Mr. Gordon Box, LG Geotechnical Engineering Unit North Carolina Department of Transportation 1020 Birch Ridge Drive Raleigh, NC 27610

RE: GEOENVIRONMENTAL PHASE II INVESTIGATION OF PARCEL 2

> 4 Brothers Food Store #302, Beroth Oil Company 800 S. State St., Yadkinville, North Carolina ESP Project No. GR22.309

TIP Number: U-5809 WBS Number: 44382.1.1 **YADKIN** County:

Description: Construct median along US 601 (State Street) from US 421 to SR 1146

(Lee Avenue) and add roundabouts at both ends of project

Dear Mr. Box:

ESP Associates, Inc. (ESP) is pleased to submit this report on our GeoEnvironmental Phase II Investigation of the subject parcel. This work was performed in accordance with your Request for Proposal (RFP) dated January 25, 2019 and our Cost Proposal dated February 1, 2019.

We appreciate the opportunity to assist you during this phase of the project. If you should have any questions concerning this report, or if we may be of further assistance, please contact us.

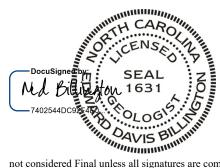

Sincerely,

ESP Associates, Inc.

Edward D. Billington, PG

Senior Geologist/Geophysicist

EDB/CJW

APPENDICES

Appendix A Soil Boring Logs

Appendix B RED Lab Laboratory Testing Report

Appendix C Chain-of-Custody Form

1.0 INTRODUCTION

The North Carolina Department of Transportation (NCDOT) is planning to construct a median along US 601 (State Street) from US 421 to SR 1146 (Lee Avenue). Roundabouts will be added at both ends of the project. The NCDOT requested that ESP Associates, Inc. (ESP) perform a Phase II Investigation of the existing right-of-way (ROW) and proposed permanent drainage utility easement (PUE) of Parcel 2 to locate possible underground storage tanks (USTs), sample soil, and delineate potential contaminated soil. Parcel 2 is located at 800 South State Street in Yadkinville, North Carolina (Figure 1). The size of the study area was approximately 0.47 acres.

2.0 HISTORY

This site is owned by Beroth Oil Company, Inc. and occupied by an active convenience store/gas station named 4 Brothers Food Store No. 302. There are 5 existing underground storage tanks (USTs) on the west side of the site. The facility ID is 00-0-000005052. According to the NCDOT RFP, a possible UST fill port was noted previously in the vacant lot on the west side of the active gas station; this was not observed during ESP's field work. Groundwater incident # 5576 is associated with this site. The NCDEQ files for Parcel 2 include the results of a 1989 investigation which report BTEX and MTBE contamination plumes in the shallow groundwater on the site. Groundwater was 8.7 feet depth and 10.3 feet depth in the ROW area at the time of the specific report (1989).

3.0 SITE OBSERVATIONS

During our February and March 2019 field work, the site was occupied by a convenience store/gas station (Figure 2). The ground in the study area was covered by asphalt pavement, concrete, and soil/grass. There were 5 active USTs on the west side of the site but outside of the proposed easement: 3 gasoline USTs (8,000 gallons each), one diesel UST (8,000 gallons), and one kerosene UST (6,000 gallons). ESP observed one abandoned monitoring well that had been grouted full on the east side of the site. There are two metal cover plates within the proposed easement on the north side of the site that appear to be associated with the active UST monitoring system. These are noted as monitoring wells on the final survey MicroStation file.

4.0 METHODS

ESP performed a geophysical study of the area designated by the NCDOT on February 19, 2019. We performed direct-push drilling, hand augering and sampling of subsurface soils within the existing ROW and proposed easement on March 5, 2019. A photoionization detector (PID) was used to screen subsurface soils in the field and select soil samples to send for laboratory analysis.

4.1 Geophysics

ESP performed an electromagnetic induction metal detector study over the accessible areas of the site using a Geonics EM61 MK2 with a line spacing of about three feet (Figures 3 through 6). Location control for the EM61 data was provided in real-time using a differential global positioning system (DGPS). We also used the DGPS to obtain the approximate location of surficial site features for correlation with the EM61 data.

4.2 Borings

ESP performed direct-push drilling and hand augering activities within the existing ROW and proposed easement of Parcel 2 using a subcontractor, SAEDACCO of Fort Mill, South Carolina. Seven borings were drilled, designated B2-1 through B2-7 (Figure 7). The soil borings were advanced using a GeoProbe 7822DT drill rig. Continuous soil samples were obtained to a depth of approximately 10 feet using two 5-foot long Macro Cores®. Soil cores varied in recovery from 1.0 to 5 feet. A hand auger was used to obtain samples from the upper 5 feet when the Macro Core recovery was low. The sampling equipment was decontaminated prior to drilling and between borings by the driller using a Liquinox® detergent solution.

4.3 Soil Sample Protocol

Representative soil samples were taken from the Macro-Core tubes at approximate one-foot intervals by the ESP field representative while wearing nitrile disposable gloves. Each sample was placed in a sealed plastic bag and then kept in a warm vehicle approximately 10 minutes prior to measuring volatile organic compound (VOC) levels in the head space of the bag with the PID. The soil samples had PID readings of less than 10 parts per million (ppm) (Table 1).

Nine soil samples were selected for laboratory analysis, as listed in Table 2. For each selected sample, an approximate 10-gram soil sample was collected from the Macro-Core tube using a Terra Core Sampler and placed into a laboratory-supplied 40-milliliter volatile organic analysis (VOA) vial containing methanol. Once sealed, the vial was labeled with the sample identification number and then shaken vigorously for about one minute. The samples were packed on ice and sent via overnight delivery to RED Lab, LLC (RED Lab), located in Wilmington, North Carolina, following proper chain-of-custody procedures (Appendix C).

RED Lab used a QED Hydrocarbon Analyzer to quantitatively analyze the soil samples using the ultraviolet fluorescence (UVF) method for benzene, toluene, ethylbenzene, and xylene (BTEX); gasoline range organics (GRO); diesel range organics (DRO); total petroleum hydrocarbons (TPH); total aromatics; polycyclic aromatic hydrocarbons (PAHs); and benzo(a)pyrene (BaP).

4.4 Groundwater

Groundwater was not encountered during the drilling investigation. Perched water was encountered at 5 feet depth in one boring on the east side of the site (B2-2).

5.0 RESULTS

5.1 Geophysics

The EM61 early time gate data show the response from both shallow and deeper metallic objects (Figure 3). The differential response reduces the effect of shallow anomalies and emphasizes anomalies from larger and more deeply buried metallic objects, such as USTs (Figure 4). The EM61 differential responses corresponded to known site features, such as buried utilities and metallic features on the ground surface. Based on the EM61 differential response, ground-penetrating radar (GPR) imaging was not required.

The EM61 early time gate response and differential response are shown on the NCDOT plan sheet on Figures 5 and 6, respectively.

5.2 Sample Data

The soil sample UVF hydrocarbon analysis results for BTEX, GRO, and DRO are presented in Table 2. The RED Lab laboratory report, which also includes results for TPH, total aromatics, PAHs, and BaP, is provided in Appendix B. Values are provided in milligrams per kilogram (mg/kg or ppm).

5.3 Sample Observations

The results of the laboratory testing indicate that BTEX and GRO were below the laboratory detection limits for the 9 samples tested. DRO was detected in 6 of 9 soil samples tested but was below the NCDEQ action level of 100 ppm.

6.0 CONCLUSIONS

6.1 Interpretation of Results

The results of the Phase II Investigation of Parcel 2 of NCDOT Project U-5809 indicate the presence of 5 active USTs outside of the existing ROW and proposed easement. The geophysical data did not indicate the presence of abandoned USTs in the study area. The results of the PID field screening and the UVF laboratory testing did not indicate the presence of petroleum hydrocarbon contamination above NCDEQ action levels in the soil in the upper 10 feet within the study area.

6.2 Geophysics

The geophysical data did not indicate the presence of abandoned USTs in the study area.

6.3 Soil

The results of the PID field screening and the UVF laboratory testing did not indicate the presence of petroleum hydrocarbon contamination above NCDEQ action levels in the soil in the upper 10 feet within the study area.

7.0 RECOMMENDATIONS

No limitations on construction activities or special handling of excavated soil are recommended for Parcel 2. Groundwater was not encountered in the upper 10 feet in the study area. However, the groundwater level may fluctuate, based on the 1989 environmental investigation performed by others, and it is possible that contaminated groundwater could be encountered at the time of construction. If groundwater is encountered during construction, it should be handled and disposed of in accordance with NCDEQ regulations.

8.0 LIMITATIONS

ESP's professional services have been performed, findings obtained, and recommendations prepared in accordance with customary principles and practices in the fields of environmental science and engineering. ESP is not responsible for the independent conclusions, opinions, or recommendations made by others based on the data presented in this report.

The passage of time may result in a change in the environmental characteristics at this site and surrounding properties. ESP does not warrant against future operations or conditions, or against operations or conditions present of a type or at a location not investigated. ESP does not assume responsibility for other environmental issues that may be associated with the subject site.

RE: GEOENVIRONMENTAL PHASE II INVESTIGATION OF PARCEL 6

Valero Gas Station, FAW JC

801 S. State St., Yadkinville, North Carolina

ESP Project No. GR22.309

TIP Number: U-5809 WBS Number: 44382.1.1 County: YADKIN

Description: Construct median along US 601 (State Street) from US 421 to SR 1146

(Lee Avenue) and add roundabouts at both ends of project

Dear Mr. Box:

ESP Associates, Inc. (ESP) is pleased to submit this report on our GeoEnvironmental Phase II Investigation of the subject parcel. This work was performed in accordance with your Request for Proposal dated January 25, 2019 and our Cost Proposal dated February 1, 2019.

We appreciate the opportunity to assist you during this phase of the project. If you should have any questions concerning this report, or if we may be of further assistance, please contact us.

Sincerely,

ESP Associates, Inc.

Edward D. Billington, PG

Senior Geologist/Geophysicist

EDB/CJW

Appendix B RED Lab Laboratory Testing Report

Appendix C Chain-of-Custody Form

Appendix D March 2003 Phase II LSA Report (selected portions)

1.0 INTRODUCTION

The North Carolina Department of Transportation (NCDOT) is planning to construct a median along US 601 (State Street) from US 421 to SR 1146 (Lee Avenue). Rounabouts will be added at both ends of the project. The NCDOT requested that ESP Associates, Inc. (ESP) perform a Phase II Investigation of the proposed right-of-way (ROW) and proposed easement of Parcel 6 to locate possible underground storage tanks (USTs), sample soil, and delineate potential contaminated soil. The study area of Parcel 6 is approximately 0.1 acre and located at 801 South State Street in Yadkinville, North Carolina.

2.0 HISTORY

This site is occupied by an active convenience store/gas station that is named Fast Track No. 116 and is owned by FAW JC. According to the NCDEQ UST Section Registry there are 3 existing USTs on the south side of the convenience store. Several monitoring wells were identified during the Phase I site visit. Two 10,000-gallon USTs reportedly were removed from a tank pit in the northwest corner of the site in 1998. The NCDEQ files indicated that a groundwater incident (#3708) was associated with this site and was closed out in 2003. NCDEQ files indicated benzene and volatile petroleum hydrocarbons (VPH) contamination were present onsite and attributed this contamination to an offsite source. Groundwater was measured at 11.1 and 13.2 feet depth below ground surface within the proposed easement in March 2003. A copy of selected portions of the site's March 2003 Limited Site Assessment report is attached as Appendix D.

3.0 SITE OBSERVATIONS

During our February and March 2019 field work, the site was occupied by a convenience store/gas station (Figure 2). The ground in the study area was covered by asphalt pavement, concrete, and grass. There were 3 active USTs on the south side of the existing building but outside of the proposed easement. None of the existing monitoring wells were within the proposed easement.

4.0 METHODS

ESP performed a geophysical study of the area designated by the NCDOT on February 19 and 27, 2019. We performed direct-push drilling and sampling of subsurface soils within the proposed ROW/easement on March 6, 2019. A photoionization detector (PID) was used to screen subsurface soils in the field and select soil samples to send for laboratory analysis. Groundwater was not encountered during the drilling investigation.

4.1 Geophysics

ESP performed a metal detector study over the accessible areas of the study area using a Geonics EM61 MK2 with a line spacing of about three feet (Figures 3 and 4). Location control was provided

in real-time using a differential global positioning system (DGPS). We collected ground-penetrating radar (GPR) data over selected EM61 anomalies using our Sensors and Software Noggin 250 GPR system. The GPR data were collected using a line spacing of one to two feet.

4.2 Borings

ESP performed direct-push drilling activities within the proposed ROW/easement of Parcel 6 using a subcontractor, SAEDACCO of Fort Mill, South Carolina. Four borings were drilled, designated B6-1 through B6-4 (Figure 7). The soil borings were advanced using a GeoProbe 7822DT drill rig. Soil samples were obtained to a depth of approximately 10 feet using two 5-foot long Macro Cores®. Soil cores varied in recovery from 3.4 to 5 feet. The sampling equipment was decontaminated prior to drilling and between borings by the driller using a Liquinox® detergent solution.

4.3 Soil Sample Protocol

Representative soil samples were taken from the Macro-Core tubes at approximate one-foot intervals by the ESP field geologist while wearing nitrile disposable gloves. Each sample was placed in a sealed plastic bag and then kept in a warm area for 5 to 10 minutes prior to measuring volatile organic compound (VOC) levels in the head space with the PID. The soil samples had PID readings of less than 10 parts per million (ppm), except for the samples from Boring B6-2, which had readings ranging from 9.4 to 46.8 ppm (Table 1 and Appendix A).

Six soil samples were selected for laboratory analysis, as listed in Table 2. For each selected sample, an approximate 10-gram soil sample was collected from the Macro-Core tube using a Terra Core Sampler and placed into a laboratory-supplied 40-milliliter volatile organic analysis (VOA) vial containing methanol. Once sealed, the vial was labeled with the sample identification number and then shaken vigorously for about one minute. The samples were packed on ice and sent via overnight delivery to RED Lab, LLC (RED Lab), located in Wilmington, North Carolina, following proper chain-of-custody procedures (Appendix C).

RED Lab used a QED Hydrocarbon Analyzer to quantitatively analyze the soil samples using the ultraviolet fluorescence (UVF) method for benzene, toluene, ethylbenzene, and xylene (BTEX); gasoline range organics (GRO); diesel range organics (DRO); total petroleum hydrocarbons (TPH); total aromatics; polycyclic aromatic hydrocarbons (PAHs); and benzo(a)pyrene (BaP).

4.4 Groundwater

Groundwater was not encountered in the four borings drilled on the site.

5.0 RESULTS

5.1 Geophysics

The EM61 early time gate data show the response from both shallow and deeper metallic objects (Figure 3). The differential response reduces the effect of shallow anomalies and emphasizes anomalies from larger and more deeply buried metallic objects, such as USTs (Figure 4). The EM61 differential responses corresponded to known site features, such as storm drains, buried utilities, and reinforced concrete. GPR data were collected over selected EM61 anomalies. The GPR data did not indicate the presence of unknown USTs within the study area.

The EM61 early time gate response and differential response are shown on the plan sheet on Figures 5 and 6, respectively.

5.2 Sample Data

The soil sample UVF hydrocarbon analysis results for BTEX, GRO, DRO, and PAHs are presented in Table 2. The RED Lab laboratory report, which includes results for TPH, total aromatics, and BaP, is provided in Appendix B. Values are provided in milligrams per kilogram (mg/kg or ppm).

5.3 Sample Observations

The results of the laboratory testing indicated that BTEX and GRO were below the laboratory detection limits for the 6 samples tested. DRO were detected above the NCDEQ action level of 100 ppm with a concentration of 159.3 ppm in sample B6-2 S1 and above laboratory detection limits in 4 of the 5 other samples. PAHs were detected in 5 out of 6 soil samples tested with values ranging from 0.002 to 2.0 ppm. BaP was below the NCDEQ Maximum Soil Contamination Concentration (MSCC) for soil-to-water of 0.096 ppm.

6.0 CONCLUSIONS

6.1 Interpretation of Results

The results of the Phase II Investigation for Parcel 6 of NCDOT Project U-5809 indicate the presence of 3 active USTs outside of the proposed easement and no abandoned USTs within the proposed easement. Petroleum hydrocarbon soil contamination was detected above the NCDEQ action level for DRO of 100 ppm in Boring B6-2, Sample S1 from a depth of 1.0 to 1.5 feet below ground surface. The RED Lab report classified the contaminant in B6-2 S1 as bituminous road tar 96.2%, suggesting the contaminant may have come from relic road bed material.

6.2 Geophysics

The geophysical data did not indicate the presence of abandoned USTs in the study area.

6.3 Soil

The results of the laboratory UVF hydrocarbon analyses indicate the presence of contaminated soil below the NCDEQ action levels for DRO of 100 ppm, except in one sample from Boring B6-2 (Figure 8). Petroleum hydrocarbon soil contamination was detected above the NCDEQ action level for DRO of 100 ppm in Boring B6-2, Sample S1 from a depth of 1.0 to 1.5 feet below ground surface within the proposed easement.

6.4 Estimated Quantities

Assuming a contaminated soil thickness of 3.0 feet and a radius of 10 feet, the volume of contaminated soil within the proposed permanent drainage/utility easement (DUE) in the vicinity of Boring B6-2 is estimated as follows:

$$\pi * R^2 * 3.0 = 942$$
 cubic feet = 35 cubic yards

7.0 RECOMMENDATIONS

ESP recommends that the soil removed from the site as part of NCDOT construction activities in the upper 3.0 feet in the vicinity of Boring B6-2 be screened for petroleum hydrocarbon contamination, properly handled, segregated, and disposed of in accordance with NCDEQ regulations.

Groundwater was not encountered in the upper 10 feet in the study area. However, the 2003 LSA report (Appendix D) indicates that benzene contamination is present in the groundwater. If groundwater is encountered during construction, it should be handled and disposed of in accordance with NCDEQ regulations.

8.0 LIMITATIONS

ESP's professional services have been performed, findings obtained, and recommendations prepared in accordance with customary principles and practices in the fields of environmental science and engineering. ESP is not responsible for the independent conclusions, opinions, or recommendations made by others based on the data presented in this report.

The passage of time may result in a change in the environmental characteristics at this site and surrounding properties. ESP does not warrant against future operations or conditions, or against operations or conditions present of a type or at a location not investigated. ESP does not assume responsibility for other environmental issues that may be associated with the subject site.

Phase II Limited Site Assessment Former Pantry Store 801 S. State Street (Hwy. 601) Yadkinville, North Carolina

H&H Job No. YOC-003

1.0 Executive Summary

Hart & Hickman, PC (H&H) has completed a Phase II Limited Site Assessment (LSA) at the former Pantry store located at 801 S. State Street (Hwy. 601) in Yadkinville, Yadkin County, North Carolina. The property is currently occupied by Texaco Fast Track, a gas station/convenience store. This Phase II LSA addresses impacts related to a former underground storage tank (UST) basin, which contained two 10,000-gallon gasoline USTs. The subject USTs were removed by others on July 10, 1988. This report was prepared on behalf of YOCO, Inc.

Soil excavation activities were conducted following UST removal in 1988. The excavation was extended to the water table. The total amount of soil removed was reported to be approximately 100 cubic yards. Following the soil removal, gasoline-range total petroleum hydrocarbons (TPH; 1,200 mg/kg) were detected in soil near the water table beneath the former excavation.

Following the detection of TPH near the water table, three monitoring wells were installed and sampled. Ground water samples collected from two monitoring wells in 1989 indicated the presence of benzene at concentrations up to 1,230 µg/l in source area monitoring well MW-1 and up to 631 µg/l in downgradient monitoring well MW-2. Both of these concentrations exceed the North Carolina ground water standard of 1 µg/l for benzene. Benzene was not detected in the ground water sample collected from "auger hole #1" (AH #1), which was situated cross-gradient of the former UST basin.

In response to the above information, the North Carolina Department of Environment and Natural Resources (DENR) issued a Notice of Regulatory Requirements (NORR) letter dated November 27, 2002. The NORR requested that it be demonstrated that impacted soils were removed to applicable

standards at the time of tank closure or that a LSA be completed. Because soil impacts were detected following tank closure excavation activities, H&H conducted a LSA.

In January 2003, H&H conducted Phase I LSA soil sampling, collected a ground water sample from existing monitoring well MW-1, and performed the land use and receptor survey. Benzene was detected in the ground water sample from MW-1 at a concentration of 44 µg/l. Since this benzene concentration exceeds the ground water standard for benzene by a factor of ten, H&H proceeded with a Phase II LSA in March 2003 in accordance with DENR guidelines.

Land Use/Risk Characterization

As part of the LSA, H&H performed a land use and risk characterization survey. The site is located in a heavily commercialized corridor along S. State Street (Hwy 601) in the Town of Yadkinville. The property is used for a gas station/convenience store, and the site is zoned Highway Business. Based on the site zoning and use, the site appears to qualify for a commercial land use classification.

No active water supply wells were identified within 1,500 ft of the subject site. Municipal water is available to the site and surrounding areas. No surface water bodies were identified within 500 ft of the site. Ground water analytical results indicate that constituent concentrations are below DENR-defined Gross Contamination Levels (GCLs). Based on the above information, the site appears to qualify for a low risk classification.

LSA Results

Soil Results

One soil boring (DPT-1) was advanced in the former UST basin to confirm the area where soil was previously removed to the water table. The soils encountered appeared to be backfill from the previous excavation. Therefore, an additional soil boring (DPT-2) was advanced adjacent to the former UST basin. Soil samples were collected in 5 ft intervals from boring DPT-2 above the water table and submitted for laboratory analyses for volatile organic compounds (VOCs), including isopropyl ether (IPE) and methyl tert-butyl ether (MTBE), and volatile petroleum hydrocarbons (VPH) by the Massachusetts Department of Environmental Protection (MADEP) Method. Soil

impacts were not detected above soil to ground water, residential, or commercial Maximum Soil Contaminant Concentrations (MSCCs).

Ground Water Results

Ground water samples were collected from four permanent shallow monitoring wells and one deeper monitoring well. The shallow wells included MW-1 (source area), MW-3 (upgradient), and MW-2 and MW-4 (both downgradient). Target compounds were detected above North Carolina standards in each of the wells sampled. Target ground water constituent concentrations do not exceed GCLs. Data from the off-site upgradient monitoring well MW-3 and on-site deeper well MW-1D indicate that an off-site source is impacting the site. Off-site gas stations are located cross-gradient and cross-gradient to upgradient of the site.

Recommendations

Based on the data collected, the site appears to qualify as a low risk commercial site. No soil impacts exceed MSCCs. Although ground water is impacted above ground water standards, impacts do not exceed GCLs, and ground water at the site has been impacted by an off-site source. No ground water remediation is required at low risk sites. As such, H&H recommends that DENR issue a risk-based no further action letter for the site.

2.0 Introduction and Site History

This Phase II LSA report documents assessment activities related to a previous release detected at a former gasoline UST basin at the former Pantry store located at 801 S. State Street (Hwy. 601) in Yadkinville, Yadkin County, North Carolina (Figure 1). The property is currently occupied by Texaco Fast Track, a gas station/convenience store. This Phase II LSA addresses impacts related to a former UST basin, which contained two 10,000-gallon gasoline USTs that were removed by others on July 10, 1988. This report was prepared on behalf of YOCO, Inc.

Soil excavation activities were conducted following UST removal in 1988. The excavation was extended to the water table. The total amount of soil removed was reported to be approximately 100 cubic yards. Following soil removal, gasoline-range TPH (1,200 mg/kg) were detected in soil near the water table beneath the former excavation.

Following the detection of TPH near the water table, three monitoring wells were installed and sampled. Ground water samples collected from two monitoring wells in 1989 indicated the presence of benzene at concentrations up to 1,230 µg/l in source area monitoring well MW-1 and up to 631 µg/l in downgradient monitoring well MW-2. Both of these concentrations exceed the North Carolina ground water standard of 1 µg/l for benzene. Benzene was not detected in the ground water sample collected from AH #1, which was situated cross-gradient of the former UST basin. Monitoring wells MW-1 and MW-2 remain at the site, but AH#1 was not located.

In response to the above information, DENR issued a NORR letter dated November 27, 2002. The NORR requested that it be demonstrated that impacted soils were removed to applicable standards at the time of tank closure or that a LSA be completed. Because soil impacts were detected following tank closure excavation activities, H&H conducted a LSA.

3.0 Receptor Information and Risk Characterization

A LSA Risk Classification and Land Use Form are provided in Appendix A. A discussion of potential receptors and land use is provided below.

3.1 Receptor Information

3.1.1 Water Supply Survey

H&H conducted a water supply well survey for the area within a 1,500-ft radius of the former UST basin. The survey was conducted by performing drive-by reconnaissance, contacting the Town of Yadkinville concerning municipal water availability, and door-to-door interviews with available property owners located within the survey area.

No active water supply wells were identified within 1,500 ft of the subject site. However, six out-of-service water supply wells were identified within 1,500 ft of the site (Figure 2). The Town of Yadkinville supplies water to all properties within the town limits, which includes the site and surrounding area. H&H observed evidence of municipal water availability (i.e., water meters and fire hydrants) in the entire survey area. According to Town of Yadkinville water department personnel, no water supply wells are to be used for any reason within the town limits, and municipal water must be used. Home owners/occupants in the area where water supply wells were observed confirmed that municipal water is used and that the observed water supply wells are not in service.

3.1.2 Surface Water

No surface water bodies were observed within 500 ft of the site. A pond is shown on the USGS topographic map of the site area approximately 500 ft west of the site; however, no pond was observed during site reconnaissance. Therefore, this pond was likely drained and/or filled.

3.1.3 Subsurface Structures

Visual observations were made for potential subsurface conduits in the vicinity of the former UST basin area. No subsurface conduits were observed in the area of the former UST basin.

3.1.4 Municipal Water Source

According to the Town of Yadkinville water department, the source of the Town of Yadkinville water is South Deep Creek which is located approximately 1 mile south of the site.

3.1.5 Property Owners and Land Use

The site is located in a heavily commercialized corridor along S. State Street (Hwy 601) in the Town of Yadkinville. The property is used for a gas station/convenience store. Access to the site is not restricted; however, the area of the former UST basin is covered with an asphalt surface. According to the Yadkin County Tax Assessors office, the subject property is owned by the Williams Family Partnership.

The site and adjacent properties located to the north, south and west are zoned Highway Business. The properties located to the east of the site are zoned Residential (Figure 2). The closest house to the subject site is located approximately 350 ft to the east. Contiguous property owners and property uses are provided in Table 1.

3.2 Risk and Land Use Characterization

The site is located in a heavily commercialized corridor along S. State Street (Hwy 601) in the Town of Yadkinville. The property is used for a gas station/convenience store, and the site is zoned Highway Business. Based on the site zoning and use, the site appears to qualify for a commercial land use classification.

No active water supply wells were identified within 1,500 ft of the subject site. Municipal water is available to the site and surrounding areas, and the Town of Yadkinville prohibits the use of water supply wells within the town limits. No surface water bodies were identified within 500 ft of the site. Ground water analytical results indicate that constituent concentrations are below GCLs (See Section 5.0). Based on the above information, the site appears to qualify for a low risk classification.

4.0 Geology and Hydrogeology

4.1 Regional Geology and Hydrogeology

According to the North Carolina Geological Survey 1985 Geologic Map of North Carolina, the site lies within the southern edge of the Sauratown Mountain Anticlinorium. The underlying bedrock of the Sauratown Mountain Anticlinorium is described as metagraywacke of Cambrian to Late Pre-Cambrian age containing quartz and mircocline porphyroblasts.

In the site area, the bedrock is generally overlain by a mantle of weathered rock termed saprolite or residuum. The saprolite consists of unconsolidated clay, silt, and sand with lesser amounts of rock fragments. Due to the range of parent rock types and their variable susceptibility to weathering, the saprolite ranges widely in color, texture and thickness. Generally, the saprolite is thickest near interstream divides and thins toward streambeds. In profile, the saprolite normally grades from clayey soils near the land surface to highly weathered rock above competent bedrock.

The occurrence and movement of ground water is typically within two separate but interconnected water-bearing zones. A shallow water-bearing zone occurs within the saprolite, and a deeper water-bearing zone occurs within the underlying bedrock.

Ground water in the shallow saprolite zone occurs in the interstitial pore spaces between the grains comprising the saprolite soils. Ground water in this zone is typically under water table or unconfined conditions. Ground water movement is generally lateral from recharge areas to small streams that serve as localized discharge points.

Secondary joints, fractures, faults, and dikes within the bedrock control the occurrence and movement of ground water in the underlying water-bearing zone within the crystalline bedrock. On a regional scale, the direction of ground water flow is typically from uplands to major streams and ground water sinks. The saprolite has a higher porosity than the bedrock and serves as a reservoir that supplies water to a network of fractures in the bedrock.

4.2 Site Geology

As part of the LSA, H&H installed two soil borings (DPT-1 and DPT-2) by direct push technology (DPT) and three additional monitoring wells (MW-3, MW-4, and MW-1D). Soils observed during the advancement of the soil borings were primarily silty clay fill with some sandy silt lenses or layers. Soil cuttings from monitoring wells on the subject property generally consisted of clayey silt and silty clay underlain by sandy to clayey silts. Soils encountered in the boring for MW-3 located on the adjacent Burger King property consisted of sandy silts. Bedrock was encountered in the deep monitoring well boring at a depth of approximately 53 ft below grade. Boring logs and well construction records are provided in Appendix B.

4.3 Site Hydrogeology

H&H surveyed the top of casing (TOC) elevation for each of the monitoring wells using an arbitrary fixed reference point. Depth to water measurements from TOC were then collected for each well, and the corresponding water surface elevations were calculated. On March 9, 2003 the depth to ground water ranged from 11.65 ft below TOC in deep monitoring well MW-1D to 15.18 ft below TOC in MW-3 (Table 2).

Based on March 2003 ground water elevations, a shallow ground water potentiometric map was constructed (Figure 4). As shown in the figure, the flow direction is generally to the south. This flow direction is consistent with previous ground water flow information collected by others and with the surface topography of the area. Based on the higher ground water elevation in deep well MW-1D as compared to shallow ground water elevations in the area, there appears to be an upward hydraulic gradient in the area of the former UST basin.

5.0 Sampling Results

5.1 Sample Collection

On January 19, 2003 H&H installed two soil borings (DPT-1 and DPT-2) using a direct push technology (DPT) rig (Figure 3). During boring advancement, soil samples were collected using a DPT sampler equipped with dedicated liners. DPT-1 was installed in the approximate center of the former UST basin to confirm the previous removal of impacted soil. This boring was advanced to a depth of 15 ft below grade. The soils encountered in boring DPT-1 appeared to be composed of fill soils to a depth of 14 ft where the water table was encountered. Because this soil boring confirmed that soil was previously removed to the water table, no soil samples were collected for laboratory analyses from this boring.

DPT-2 was installed immediately adjacent to the former UST basin excavation area. Soil samples from DPT-2 also indicated the presence of fill soils; however, the soils were much more compact than soil encountered in DPT-1 in the former UST excavation. DPT-2 was advanced to approximately 15 ft below grade. In accordance with DENR guidance, soil samples were collected at approximate 5 ft intervals above the water table surface. Therefore, two soil samples were collected at depth intervals of 2.5 to 5 ft and 7.5 to 10 ft below grade. The samples were submitted to Test America, Inc., a North Carolina certified laboratory, for analyses of VOCs (including IPE and MTBE) by EPA Method 8260B and VPH by the MADEP Method.

A ground water sample was collected from existing source area monitoring well MW-1 in January 2003 and analyzed for VOCs (including IPE, MTBE and ethylene dibromide [EDB]) by EPA Method 6210D, VPH by the MADEP Method, and total lead by EPA Method 6010B using 3030C preparation. Prior to sample collection, the monitoring well was purged using a disposable polyethylene bailer until pH, conductivity, and temperature stabilized.

Based on ground water impacts detected in MW-1 more than 10 times ground water standards, H&H sampled existing well MW-2 and installed three additional well in March 2003. With these

wells, the Phase II LSA monitoring wells included MW-1 (source area), MW-3 (upgradient), MW-2 and MW-4 (both downgradient), and MW-1D (deep source area).

The monitoring wells were installed by Richard Simmons Drilling, Inc., a North Carolina certified well driller, using air rotary drilling techniques. Prior to installation of off-site monitoring well MW-3, H&H obtained an access agreement with Burger King Corporation and obtained a monitoring well construction permit (no. UST-MO040177) from DENR. Monitoring well MW-3 was completed to a depth of 25 ft below grade, and MW-4 was completed to a depth of 20 ft below grade. The shallow wells consist of 2-inch diameter PVC that includes a 15 ft screen interval placed to bracket the water table. The deeper well MW-1D is a Type III well with a 6-inch diameter PVC surface casing to a depth of 40 ft and a 2-inch diameter inner PVC casing and screen to a depth of 53 ft with a 5 ft bottom screen interval. A summary of well completion data is provided in Table 2.

Following well development and purging, ground water samples were collected from MW-2, MW-3, MW-4, and MW-1D on March 6 and 7, 2003. These ground water samples were submitted for analyses of VOCs including IPE and MTBE by EPA Method 6210D, EDB by EPA Method 504.1, VPH by the MADEP Method, and lead by EPA Method 6010B using 3030C preparation. In addition, monitoring well MW-1 was sampled on March 6, 2003 for EDB analyses by EPA Method 504.1.

Laboratory-supplied sample bottles were used for sample collection for both soil and ground water samples. A chain-of-custody record was completed for samples collected and included sample description, date collected, time collected, matrix, sample container information, and analyses required. The chain-of-custody was signed by H&H prior to placement in an iced cooler for shipment to the laboratory. Laboratory analytical data sheets are provided in Appendix C.

5.2 Soil Sampling Results

Analytical results from the two soil samples collected from soil boring DPT-2 indicate the presence of low concentrations of acetone (0.0421 mg/kg) in the shallow sample and carbon disulfide (up to 0.00233 mg/kg) in both samples (Table 3). These compounds were not detected in ground water

and may be laboratory contaminants. Nevertheless, these soil constituent concentrations do not exceed soil-to-ground water, residential, or commercial MSCCs. No other analyzed constituents were identified in soil above laboratory method detection limits.

5.3 Ground Water Sampling Results

The ground water analytical results indicate constituents exceeding North Carolina standards in each of the monitoring wells sampled (Table 4). Constituents identified in at least one monitoring well above standards included benzene (up to 119 μ g/l), 1,2-dichloloroethene (up to 5.3 μ g/l), MTBE (up to 276 μ g/l), VPH as C5-C8 aliphatics (up to 1,320 μ g/l), and VPH as total C9-C22 aromatics (up to 294 μ g/l). None of the ground water detections exceed DENR-defined GCLs. The ground water plume extent as estimated using benzene concentrations is depicted on Figure 5.

The highest benzene and VPH concentrations were detected in upgradient off-site monitoring well MW-3. Based on the detections in monitoring well MW-3, it appears that an off-site plume is impacting the subject property. Based on the potentiometric map, the most likely location for an off-site source would be located to the north or north-northwest of the subject property. Currently, there are two gas stations in the site area, an Amoco located approximately 100 ft to the west and a Phillips 66 gas station located approximately 250 ft to the northwest (Figure 2).

1,2-dichloroethane (DCA) was detected in UST area well MW-1 (5.3 µg/l) but was not detected in upgradient well MW-3. DCA was a constituent in older (leaded) gasoline. In addition, impacted source area soils were removed from the subject property UST basin. Based on the DCA detection and previous source area removal, a portion of the impacted ground water on the subject property may be from the former UST basin located on the subject property.

Ground water impacts were detected in the deeper monitoring well MW-1D. VOCs and VPH as C5-C8 aliphatics were detected in MW-1D. The only VOCs detected in MW-1D above standards are benzene and MTBE, which are considered to be relatively mobile gasoline constituents. The VOC concentrations in MW-1D are similar in magnitude to those detected in nearby source area

shallow well MW-1. The low level impacts detected in monitoring well MW-1 would not typically expected to cause similar concentrations 30 to 35 ft below the water table such as detected in MW-1D. Further, 1,2-DCA was not detected in monitoring well MW-1D. In addition, as mentioned in Section 4.3, there appears to be an upward hydraulic gradient near the source area. Based on these considerations, the impacts in MW-1D appear to be primarily related to the off-site source.
