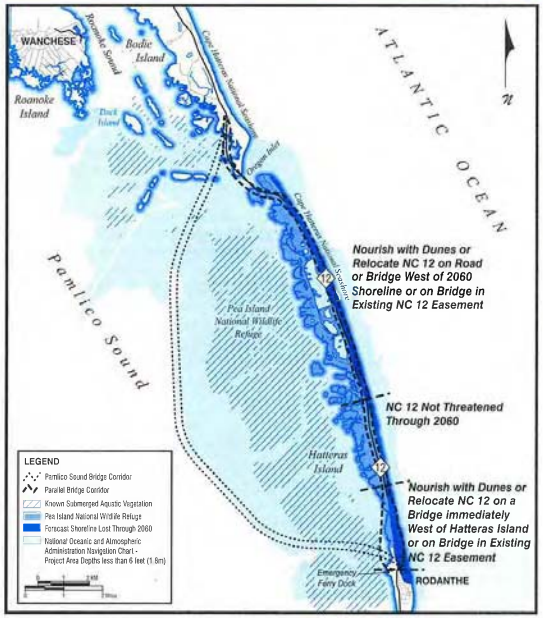
	With Phased Approach/ Rodanthe Bridge	This alternative would include a modified Oregon Inlet bridge and elevating portions of NC 12 through the Refuge and northern Rodanthe on new bridges within the existing NC 12 easement. It would be built in four phases, with the first phase being the Oregon Inlet bridge and additional phases being built as necessitated by shoreline erosion. With this alternative, the bridge and approach roadway would begin in Rodanthe approximately 1.1 miles south of the Refuge boundary (at a point that is south and west of where the projected 2060 worst-case shoreline crosses NC 12). Once all four phases are completed, the NC 12 bridge would extend from this point north to Oregon Inlet except for the 2.1 mile length of NC 12 in the southern half of the Refuge that would not be threatened by erosion prior to 2060. Access to properties adjacent to the bridge in Rodanthe would be provided by a one-lane, one-way frontage road on each side of the NC 12 bridge. Three crossovers between the two frontage roads underneath the NC 12 bridge would be provided south of the Refuge boundary.	Displaces 2 homes and a commercial building containing a business and a residence, plus 2 additional businesses partially affected; NC 12 right-of-way widened in Rodanthe; access to homes and businesses in Rodanthe maintained, but travel would become circuitous in areas with frontage roads; access to Refuge limited to two locations, so access lost to Refuge facilities except fishing at north end of Hatteras Island; would affect beach activities once shoreline erodes and bridge is located on beach or in ocean; substantial visual impacts on landscape of Refuge and in Rodanthe where an elevated roadway would be introduced into views for 1.1 miles; adverse effect on Refuge as an historic resource; adverse effect on Chicamacomico Life Saving Station and Rodanthe Historic District because of change in visual setting.	4.6 perma natural wetl wetlan plov docur
	With Phased Approach/ Rodanthe Nourishment	This alternative also would include a modified Oregon Inlet bridge and elevating portions of NC 12 through the Refuge and northern Rodanthe on new bridges within the existing NC 12 easement. It also would be built in four phases, with the first phase being the Oregon Inlet bridge and additional phases being built as necessitated by shoreline erosion. With this alternative, the bridge and approach roadway would begin in Rodanthe approximately 0.3 mile south of the Refuge boundary. Once all four phases are completed, the NC 12 bridge would extend from this point north to Oregon Inlet except for the 2.1 mile length of NC 12 in the southern half of the Refuge that would not be threatened by erosion prior to 2060. Access to properties adjacent to the bridge in Rodanthe would be provided by a one-lane, one-way frontage road on each side of the NC 12 bridge. One crossover between the one-way frontage roads would be provided immediately south of the Refuge boundary. South of the bridge, NC 12 in Rodanthe would be protected through 2060 by beach nourishment (repeated every four years) for a total distance of approximately 6,000 feet at the southern end of the Refuge and in northern Rodanthe.	No displacements; NC 12 right-of-way widened in Rodanthe; access to homes and businesses in Rodanthe maintained, but travel would become circuitous in areas with frontage roads; access to Refuge limited to two locations, so access lost to Refuge facilities except fishing at north end of Hatteras Island; would affect beach activities once shoreline erodes and bridge is located on beach or in ocean; substantial visual impacts on landscape of Refuge and in Rodanthe where an elevated roadway would be introduced into views for 0.3 mile; adverse effect on Refuge as an historic resource; uses minor amount of Refuge (a SNHA) lands for periodic nourishment of 1,500 feet of seashore.	3.7 perma natural wetl wetlan plov docun



ATURAL RESOURCE IMPACTS	OTHER CONSIDERATIONS
truction dredging for 8.0 miles.	Potential storm-related island breach location at southern end of Refuge bypassed; no Refuge compatibility determination needed.
s of natural plant community used; 4.8 acres of wetland filled.	
s of natural plant community used; 4.2 acres of wetland filled.	
tion dredging for 2,000 feet; 2,400-nstruction haul road west of Bodie Island.	Refuge compatibility determination needed.
s of natural plant community used; res of wetland filled; 6.0 acres of y wetland impacts; green sea turtle g plover (threatened species) have ocumented and habitat present in project area.	Risk of storm-related island breach at southern end of Refuge, could take 3 to 6 months to close; Refuge compatibility determination needed.
s of natural plant community used; res of wetland filled; 6.0 acres of y wetland impacts; green sea turtle g plover (threatened species) have ocumented and habitat present in project area.	Potential storm-related island breach location bridged; Refuge compatibility determination needed.

Re: Resolution urging North Carolina Department of Transportation and the U. S. Fish and Wildlife Division, U. S. Department of the Interior, to replace the aging Herbert C. Bonner Bridge over Oregon Inlet with a parallel bridge immediately

Dear Governor:

At the August 13, 2007 meeting, the Kill Devil Hills Board of Commissioners unanimously approved the *Resolution urging North Carolina Department of Transportation and the U. S. Fish and Wildlife Division, U. S. Department of the Interior, to replace the aging Herbert C. Bonner Bridge over Oregon Inlet with a parallel bridge immediately.*

The Herbert C. Bonner Bridge is a critical transportation link to and from Hatteras Island and is of vital importance to the quality of life of the residents of Hatteras Island and Dare County, North Carolina.

Issues of public safety, business and commerce, and tourism must be included when considering the importance of a safe and secure structure across Oregon Inlet. The Herbert C. Bonner Bridge has reached the end of its reasonable service life as evidenced by the recent inspection done by the North Carolina Department of Transportation, where the ***bridge received a rating of two out of 100 points for structural sufficiency.***

The North Carolina Department of Transportation has presented two alternative plans to replace the bridge and the Kill Devil Hills Board of Commissioners endorses the immediate construction of a parallel bridge.

We are pleased to provide a copy of the resolution to you and will appreciate your assistance in this area.

Sincerely yours,

Raymond P. Sturza, II

TOWN OF KILL DEVIL HILLS

Land Where Flight Began

Resolution urging the North Carolina Department of Transportation and the U.S. Fish and Wildlife Division, U.S. Department of the Interior, to replace the aging Herbert C. Bonner Bridge over Oregon Inlet with a parallel bridge immediately

WHEREAS, the Herbert C. Bonner Bridge spanning Oregon Inlet is a critical transportation link to and from Hatteras Island; and,

WHEREAS, the bridge is of vital importance to the quality of life of the residents of Hatteras Island and Dare County; and

WHEREAS, the related issues of public safety, business and commerce, and tourism must be included when considering the importance of a safe and secure structure across Oregon Inlet; and

WHEREAS, one of the primary reasons visitors come to the Outer Banks are our natural, cultural, and historic resources; and

WHEREAS, south of Oregon Inlet is located the Pea Island National Wildlife Refuge which is a popular migratory pathway for more than 400 species of birds; the majority of the Cape Hatteras National Seashore – our nation's first national seashore; the Cape Hatteras Lighthouse; the Chicamacomico Lifesaving Station; the Bodie Island Lighthouse; and miles and miles of America's greatest public beaches; and

WHEREAS, more than five million people visit Dare County's Outer Banks each year, annually generating in excess of $620 million in direct tourism expenditures; and

WHEREAS, 26% of Dare County's tourism related revenues are generated by Hatteras Island visitors, including a majority of the Northern Dare Beaches visitors who, during their stay on the Outer Banks, make a day trip to Hatteras and Ocracoke Islands, via the bridge over Oregon Inlet; and

WHEREAS, the Herbert C. Bonner Bridge has been recently inspected by the North Carolina Department of Transportation and given a Structural Sufficiency Rating of two out of 100 points; and

WHEREAS, the Herbert C. Bonner Bridge has reached the end of its reasonable service life and the North Carolina Department of Transportation has presented two alternative plans to replace the bridge; and

WHEREAS, the Kill Devil Hills Board of Commissioners deplores the loss of life caused by the recent collapse of the Interstate 35W Bridge in Minneapolis, Minnesota and has the greatest sympathy for all affected by this tragic event; and

WHEREAS, it is incumbent on all levels of government to protect human safety; and

WHEREAS, continuing to delay construction of the replacement to the Bonner Bridge places public safety, business and commerce, and tourism in our area at potential risk; and

WHEREAS, the Town of Kill Devil Hills has gone on record in support of construction of a bridge parallel to the existing Herbert C. Bonner Bridge and the preservation of the terminal rock groin on the southside of Oregon Inlet and continued fortification of the groin as the chief stabilizing defense of the northernmost end of Hatteras Island;

NOW THEREFORE BE IT RESOLVED, that the Kill Devil Hills Board of Commissioners urges the North Carolina Department of Transportation, the U.S. Fish and Wildlife Service, and all other involved entities to immediately begin construction on a bridge parallel to the existing Herbert C. Bonner Bridge, maintain the navigational channel through Oregon Inlet, and provide no less than equal access to the entirety of Hatteras Island also known as Pea Island.

Adopted this 13th day of August 2007.

Re: Resolution Urging the North Carolina Department of Transportation, U. S. Fish and Wildlife Division, and the U. S. Department of the Interior, to Replace the Aging Herbert C. Bonner Bridge Over Oregon Inlet with a Parallel Bridge Immediately

Dear Governor,

At the September 4, 2007 Town Council meeting the Kitty Hawk Town Council unanimously approved the *Resolution Urging the North Carolina Department of Transportation, U. S. Fish and Wildlife Division, and the U. S. Department of the Interior, to Replace the Aging Herbert C. Bonner Bridge Over Oregon Inlet with a Parallel Bridge Immediately.*

As you may know, the Herbert C. Bonner Bridge is a critical transportation link to and from Hatteras Island and is of vital importance to the quality of life of the residents of Hatteras Island and Dare County, North Carolina.

The issues of public safety, business, commerce, and tourism cannot be ignored when considering the safe transport of vehicles across the Oregon Inlet. The Herbert C. Bonner Bridge has reached the end of its reasonable service life as evidenced by its recent inspection by the North Carolina Department of Transportation, where the bridge received a rating of two (2) out of a possible one hundred (100) points for structural sufficiency.

The North Carolina Department of Transportation has presented two alternative plans to replace the bridge and the Kitty Hawk Town Council endorses the immediate construction of a parallel bridge.

We are pleased to provide a copy of the resolution to you and will appreciate your assistance in this regard.

Sincerely,

Clifton G. Perry, Mayor

FISH AND WILDLIFE SERVICE
Raleigh Field Office
Post Office Box 33726
Raleigh, North Carolina 27636-3726

July 10, 2008

John F. Sullivan, III, P.E.
Federal Highway Administration
310 New Bern Avenue, Suite 410
Raleigh, North Carolina 27601

Dear Mr. Sullivan:

This transmits the U.S. Fish and Wildlife Service (USFWS) Raleigh Field Office's biological and conference opinions based on our review of the proposed replacement of the Herbert C. Bonner Bridge (Bridge No. 11 over Oregon Inlet) in Dare County, North Carolina (TIP No. B-2500). These opinions assess the effects of the project on the piping plover (*Charadrius melodus*), loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas*), and leatherback sea turtle (*Dermochelys coriacea*), and proposed critical habitat for wintering piping plovers. These opinions are provided in accordance with section 7(a)(2) of the Endangered Species Act of 1973 (ESA), as amended (16 U.S.C. 1531 *et seq.*). This document addresses the requirements of the ESA but does not address other environmental statutes such as the National Environmental Policy Act or Fish and Wildlife Coordination Act. Your March 5, 2008 request for formal consultation was received on March 6, 2008.

Since the proposed project is a multi-phased project which will be staggered over more than 24 years, and since final designs for each phase are not yet developed, the USFWS plans to proceed with a form of a programmatic consultation known as an appended consultation. In this appended programmatic consultation, the USFWS has conducted the required analysis of the entire project based on what is known at the present time, and one programmatic biological and conference opinion has been developed for the overall project. In the following opinions we have determined that the project is not likely to jeopardize the continued existence of the piping plover, loggerhead sea turtle, green sea turtle, and leatherback sea turtle, and is not likely to destroy or adversely modify proposed critical habitat for wintering piping plovers. The USFWS has issued incidental take for these species which reflect the maximum potential take for the entire project over the proposed extended timeframe of the project.

As additional design information is developed for subsequent phases of the project, this information must be provided to us so that it may be appended to the existing biological opinion. The USFWS will then analyze the new information for each subsequent phase of the project to insure that the take associated with each future phase, cumulatively, does not exceed the maximum amount of take authorized in the incidental take statement included in this biological opinion. If the scope of future phases of the project should differ significantly from the

conceptual design information, or if the cumulative amount of take should exceed that authorized, then consultation will need to be reinitiated. The reasonable and prudent measures, and associated terms and conditions, contained within this biological opinion apply to the overall project; however, as designs for subsequent phases are developed, additional reasonable and prudent measures may be necessary to minimize the level of take.

If you have any questions concerning this biological opinion, please contact me at (919) 856-4520 (Ext. 11).

Sincerely,

Pete Benjamin
Field Supervisor

The following opinions are based on information provided in the March 2008 biological assessment (BA)(FHWA and NCDOT 2008a), the April 8, 2008 addendum to the BA (FHWA and NCDOT 2008b, *in litt.*), the *Supplement to the 2005 Supplemental Draft Environmental Impact Statement and Draft Section 4(f) Evaluation* (SSDEIS)(FHWA and NCDOT 2007), meetings, telephone conversations, emails, field investigations, and other sources of information. A complete administrative record of this consultation is on file at this office.

CONSULTATION HISTORY

1997 – The Federal Highway Administration (FHWA) initiates formal consultation on an earlier version of the proposed project.

1998 – After several months of discussions between the USFWS and the North Carolina Department of Transportation (NCDOT), both parties agreed that formal consultation was premature.

December 12, 2007 – The USFWS met with FHWA and NCDOT to discuss the preparation of a BA.

March 6, 2008 – The USFWS received a letter from the FHWA, dated March 5, 2008, with the attached BA, requesting formal consultation for the replacement of the Herbert C. Bonner Bridge.

March 13, 2008 – The USFWS sent a letter to FHWA stating that all information required for initiation of consultation was either included with their March 5, 2008 letter or was otherwise available.

April 9, 2008 – The USFWS received an addendum to the BA dated April 8, 2008. The addendum clarified several issues and provided revised Figures 1 and 4.

June 4, 2008 – The USFWS provided the FHWA and NCDOT with a draft biological opinion.

June 11, 2008 – The USFWS met with the FHWA and NCDOT to discuss the draft biological opinion and reasonable and prudent measures.

July 9, 2008 – The USFWS met with NCDOT to discuss the draft reasonable and prudent measures.

BIOLOGICAL AND CONFERENCE OPINIONS

I. DESCRIPTION OF PROPOSED ACTION

The existing Bonner Bridge is a two-lane bridge that takes NC 12 across Oregon Inlet and connects Bodie Island with Hatteras Island in Dare County, North Carolina. Bonner Bridge is 2.4 miles long and is located at the northern end of the action area. Existing NC 12 within the

action area is a two-lane paved road extending southward from the southern end of the bridge for approximately 13.5 miles to the southern project terminus at Rodanthe. The total length of the project from the north terminus to the south terminus is 16.1 miles long. However, construction will only occur along approximately 14.0 miles. The proposed action, known as the Phased Approach/Rodanthe Bridge Alternative, is a four-phased project which includes the following:

- Phase I – replace the existing Bonner Bridge with a new 2.6 mile long bridge slightly to the west of the existing bridge – approximate construction timeframe 2009-2013
- Phase II – elevate approximately 5.6 miles of NC 12 onto three bridges – to begin approximately 2013-2015
- Phase III – elevate approximately 1.9 miles of NC 12 onto one bridge – to begin approximately 2019-2020
- Phase IV – elevate approximately 2.6 miles of NC 12 onto two bridges – to begin approximately 2029-2030

On Hatteras Island, NCDOT asserts that construction will be confined to the existing NC 12 right-of-way. A more detailed project description of the Phased Approach/Rodanthe Bridge Alternative can be found in Section 2.2 of the SSDEIS (FHWA and NCDOT 2007).

The timing of the construction of Phases II to IV is based on assumptions corresponding to forecast shoreline erosion trends and maintaining minimum 230-foot buffer distance between the existing NC 12 edge of pavement and the active shoreline. These assumptions are based on worst-case scenario modeling of shoreline erosion and the location and likelihood of future breaches on Hatteras Island. Since these are forecasts only, the exact timing and scope of each phase could change based on the reality of future shoreline erosion. As such, project descriptions of Phases II, III and IV should be viewed as approximations. The USFWS suspects that one substantial hurricane in the interim could dramatically change the predictions of worst-case scenario modeling. Although Phases II to IV will initially be built over land ostensibly within existing NCDOT right-of-way, based on shoreline erosion models, up to 8.0 miles of the bridges may ultimately be in open water by 2060.

Action Area

The action area lies within the North Carolina Outer Banks and is comprised of a dynamic barrier island system formed by wind and wave action. The barrier islands that make up the Outer Banks are sand ridges with underlying layers of limestone, sand, and clay. The action area extends from Rodanthe on Hatteras Island north to the southern end of Bodie Island and includes that portion of Hatteras Island (from the east to west shore), the area of the Atlantic Ocean one-half mile east of the Hatteras Island shoreline, portions of Oregon Inlet, and the southern tip of Bodie Island. It passes through the Cape Hatteras National Seashore (CAHA) and encompasses the Pea Island National Wildlife Refuge (PINWR). Though largely undeveloped, most of the action area consists of natural vegetation communities that have been influenced by past and present human disturbances. The construction and maintenance of an artificial sand berm along the seaward side of NC 12 has significantly interrupted the natural barrier island ecosystem processes (e.g. limiting overwash and disrupting island migration).

Conservation Measures

Conservation measures represent actions, pledged in the project description, that the action agency will implement to minimize the effects of the proposed action and further the recovery of the species under review. Such measures should be closely related to the action and should be achievable within the authority of the action agency. Since conservation measures are part of the proposed action, their implementation is required under the terms of the consultation. The FHWA and NCDOT have proposed the following conservation measures.

- The Phased Approach/Rodanthe Bridge Alternative will allow natural shoreline migration and the formation of new inlet habitats to occur.
- The project will incorporate the most current BMPs to reduce habitat degradation from stormwater runoff pollution.
- Phase I of the project will be built at least 125 feet farther west of the Bonner Bridge and currently occupied piping plover habitat.
- NCDOT does not anticipate the use of explosives during construction or demolition of the existing bridge.
- The NCDOT contractor will use pipeline or clamshell dredging, rather than a hopper dredge to minimize effects to sea turtles.
- No permanent light fixtures will be installed on the bridge or the approaches (with the exception of navigation lights as required by the U.S. Coast Guard).
- Seabeach amaranth surveys will be conducted at least one year prior to initiating bridge construction activities.
- Temporary facilities such as haul roads that affect proposed critical habitat will be removed as soon as possible.

II. STATUS OF THE SPECIES/CRITICAL HABITAT

A. Species/critical habitat description

Piping plover

The piping plover is a small, pale-colored shorebird, about seven inches long with a wingspan of about 15 inches (Palmer 1967). On January 10, 1986, the piping plover was listed as endangered in the Great Lakes watershed and threatened elsewhere within its range, including migratory routes outside of the Great Lakes watershed and wintering grounds (USFWS 1985). Piping plovers were listed principally because of habitat destruction and degradation, predation, and human disturbance. Protection of the species under the ESA reflects the species' precarious status range-wide. Three separate breeding populations have been identified, each with its own recovery criteria: the Northern Great Plains (threatened), the Great Lakes (endangered), and the Atlantic Coast (threatened). The piping plover winters in coastal areas of the U.S. from North Carolina to Texas, and along the coast of eastern Mexico and on Caribbean islands from Barbados to Cuba and the Bahamas (Elliott-Smith and Haig 2004). Information from

observation of color-banded piping plovers indicates that the winter ranges of the breeding populations overlap to a significant degree.

The recovery objective for the Great Lakes population includes:

> at least 150 pairs (300 individuals), for at least five consecutive years, with at least 100 breeding pairs (200 individuals) in Michigan and 50 breeding pairs (100 individuals) distributed among sites in other Great Lakes states; five-year average fecundity is within the range of 1.5-2.0 fledglings per pair, per year, across the breeding distribution, and ten-year population projections indicate the population is stable or continuing to grow above the recovery goal; ensure protection and long-term maintenance of essential breeding and wintering habitat, sufficient in quantity, quality, and distribution to support the recovery goal of 150 pairs (300 individuals); genetic diversity within the population is deemed adequate for population persistence and can be maintained over the long-term; and, agreements and funding mechanisms are in place for long-term protection and management activities in essential breeding and wintering habitat (USFWS 2003).

The recovery objective for the northern Great Plains population includes:

> sustaining 2,300 pairs of birds for at least 15 years, meeting recovery objectives for birds in prairie Canada, and providing long term protection of essential breeding and wintering habitat.

The recovery objective for the Atlantic Coast population includes:

> verification of the adequacy of a 2,000-pair population of piping plovers to maintain heterozygosity and allelic diversity over the long term; achieve five-year average productivity of 1.5 fledged chicks per pair in each of the four recovery units; institute long-term agreements among cooperating agencies, landowners, and conservation organizations to assure protection and management sufficient to maintain the target populations in each recovery unit and average productivity; and, ensure long-term maintenance of wintering habitat, sufficient in quantity, quality, and distribution to maintain survival rates for a 2,000-pair population (USFWS 1996).

The recovery plan for the Atlantic Coast population of the piping plover (USFWS 1996) delineates four recovery units within the population: Atlantic Canada, New England, New York-New Jersey, and Southern (Delaware, Maryland, Virginia, and North Carolina). Extensive efforts to observe and report sightings of greater than 1,400 Atlantic Coast piping plovers color-banded in Virginia, Maryland, Massachusetts, and five Eastern Canadian provinces between 1985 and 2003 have documented many inter-year movements among sites within recovery units, but few records of plovers breeding outside the recovery unit where they were banded (Loegering 1992, Cross 1996, USFWS 1996, Amirault et al. 2005), supporting the premise that immigration and emigration have relatively little influence on abundance trends at the scale of the recovery unit.

Recovery criteria established within the recovery plan defined population and productivity goals for each recovery unit, as well as for the population as a whole. The recovery objective for the Atlantic Coast population is to increase and maintain for five years a total of 2,000 breeding pairs, distributed among the four recovery units – Atlantic Canada, 400 pairs; New England, 625

pairs; New York-New Jersey, 575 pairs; and, Southern, 400 pairs. Attainment of these goals for each recovery unit is an integral part of a piping plover recovery strategy that seeks to reduce the probability of extinction for a population with low rates of inter-regional dispersal by: (1) contributing to the population total, (2) reducing vulnerability to environmental variation (including catastrophes such as hurricanes, oil spills, or disease), (3) increasing likelihood of genetic interchange among subpopulations, and (4) promoting re-colonization of any sites that experience declines or local extirpations due to low productivity or temporary habitat succession. The plan further states: "A premise of this plan is that the overall security of the Atlantic Coast piping plover population is profoundly dependent upon attainment and maintenance of the minimum population levels for the four recovery units. Any appreciable reduction in the likelihood of survival of a recovery unit will also reduce the probability of persistence of the entire population."

The USFWS has designated critical habitat for the piping plover on three occasions. Two of these designations protected different breeding populations of the piping plover. Critical habitat for the Great Lakes breeding population was designated May 7, 2001 (USFWS 2001a), and critical habitat for the northern Great Plains breeding population was designated September 11, 2002 (USFWS 2002). The USFWS designated critical habitat for wintering piping plovers on July 10, 2001 (USFWS 2001b). Wintering piping plovers may include individuals from the Great Lakes and northern Great Plains breeding populations as well as birds that nest along the Atlantic coast. The three separate designations of piping plover critical habitat demonstrate the diversity of constituent elements among the two breeding populations and wintering piping plovers.

Designated critical habitat for wintering piping plovers originally included approximately 1,798 miles of mapped shoreline and 165,211 acres of mapped area along the coasts of North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas.

The primary constituent elements for piping plover wintering habitat are those biological and physical features that are essential to the conservation of the species. These areas typically include those coastal areas that support intertidal beaches and flats and associated dune systems and flats above annual high tide (USFWS 2001b). Primary constituent elements of wintering piping plover critical habitat include sand or mud flats or both with no or sparse emergent vegetation. Adjacent unvegetated or sparsely vegetated sand, mud, or algal flats above high tide are also important, especially for roosting piping plovers (USFWS 2001b). The units designated as critical habitat are those areas that have consistent use by piping plovers and that best meet the biological needs of the species. The amount of wintering habitat included in the designation appears sufficient to support future recovered populations, and the existence of this habitat is essential to the conservation of the species. Additional information on each specific unit included in the designation can be found at 66 Federal Register 36038 (USFWS 2001b).

Since the designation of wintering critical habitat, four units in North Carolina were vacated and remanded back to the USFWS for reconsideration by Court order (Cape Hatteras Access Preservation Alliance v. U.S. Department of Interior (344 F. Supp. 2d 108 (D.D.C. 2004)). The four critical habitat units vacated were NC-1, NC-2, NC-4, and NC-5, and all occurred within CAHA. On June 12, 2006, the USFWS proposed to amend and re-designate these four units as

critical habitat for wintering piping plover (USFWS 2006a). These units encompass the primary constituent elements found at Bodie Island Spit, Cape Point, Hatteras Spit and Ocracoke Spit within CAHA. On May 15, 2008, the USFWS proposed a revised designation of critical habitat which would add areas to units NC-1 and NC-4 (USFWS 2008d).

Loggerhead sea turtle

The loggerhead sea turtle, listed as a threatened species on July 28, 1978 (NMFS and USFWS 1978), inhabits the continental shelves and estuarine environments along the margins of the Atlantic, Pacific, and Indian Oceans. Loggerhead turtles nest within the continental U.S. from Louisiana to Virginia. Major nesting concentrations are found on the coastal islands of North Carolina, South Carolina, and Georgia, and on the Atlantic and Gulf coasts of Florida (Hopkins and Richardson 1984).

Adults and sub-adults have a reddish-brown carapace (top of shell). Scales on the top and sides of the head and top of the flippers are also reddish-brown, but have yellow borders. The neck, shoulders and limb bases are dull brown on top and medium yellow on the sides and bottom. The plastron (underside of shell) is also medium yellow. Adult average size is 36 inches straight carapace length; average weight is 253 pounds. Hatchlings are dull brown in color. Average size at hatching is 1.8 inches long; average weight is 0.7 ounces. Mating takes place from late March to early June, and eggs are laid throughout the summer (NMFS and USFWS 1991b).

The recovery objectives for the southeastern U.S. population of the loggerhead turtle (NMFS and USFWS 1991b) include:

> over a period of 25 years, the adult female population in Florida is increasing, and in North Carolina, South Carolina, and Georgia nesting numbers are returning to pre-listing levels. For North Carolina, that equates to 800 nests per year. For South Carolina and Georgia nesting numbers must be 10,000 and 2,000 nests per year, respectively. These above conditions must be met with data from standardized surveys which will continue for at least five years after recovery. Furthermore, at least 25 percent of all available nesting beaches must be in public ownership, distributed over the entire nesting range and encompassing at least 50 percent of the nesting activity within each state. In addition, all priority one tasks identified in the recovery plan must be successfully implemented (NMFS and USFWS 1991b).

No critical habitat has been designated for the loggerhead turtle. However, on March 5, 2008, the National Marine Fisheries Service (NMFS) announced a 90-day finding for a petition to reclassify loggerhead turtles in the western North Atlantic Ocean as a Distinct Population Segment with endangered status and designate critical habitat (NMFS 2008).

Green sea turtle

The green sea turtle was federally listed as a protected species on July 28, 1978 (NMFS and USFWS 1978). Breeding populations of the green turtle in Florida and along the Pacific Coast of Mexico are listed as endangered; all other populations are listed as threatened. The green turtle has a worldwide distribution in tropical and subtropical waters. Major green turtle nesting

colonies in the Atlantic occur on Ascension Island, Aves Island, Costa Rica, Suriname, and Trindade Island, Brazil.

Adult green turtles may reach a size of 39 inches in length and weigh 397 pounds. The carapace is smooth and is gray, green, brown, and black. The plastron is yellowish white. Hatchlings weigh about 0.9 ounces and are about two inches long. Hatchlings are black on top and white on the bottom (NMFS and USFWS 1991a).

Within the U.S., green turtles nest in small numbers in the U.S. Virgin Islands and Puerto Rico, and in larger numbers along the east coast of Florida, particularly in Brevard, Indian River, St. Lucie, Martin, Palm Beach, and Broward Counties (NMFS and USFWS 1991a). Nesting also has been documented along the Gulf coast of Florida from Escambia County through Franklin County in Northwest Florida and from Pinellas County through Collier County in Southwest Florida (FFWCC 2006b). Green turtles have been known to nest in Georgia, but only on rare occasions (GDNR 2004). The green turtle also nests sporadically in North Carolina and South Carolina (Woodson and Webster 1999, South Atlantic Fishery Management Council 2008).

Recovery objectives for the U.S. population of the green turtle (NMFS and USFWS 1991a) include:

> over a period of 25 years, that the level of nesting in Florida has increased to an average of 5,000 nests per year for at least six years where nesting data are based on standardized surveys; at least 25 percent of all available nesting beaches is in public ownership and encompasses at least 50 percent of the nesting activity; and a reduction in stage class mortality is reflected in higher counts of individuals on foraging grounds. In addition, all priority one tasks identified in the recovery plan must be successfully implemented (NMFS and USFWS 1991a).

Critical habitat for the green sea turtle has been designated for the water surrounding Culebra Island, Puerto Rico and its outlying keys.

Leatherback sea turtle

The leatherback sea turtle, listed as an endangered species on June 2, 1970 (USFWS 1970), nests on shores of the Atlantic, Pacific, and Indian Oceans. Non-breeding animals have been recorded as far north as the British Isles and the Maritime Provinces of Canada and as far south as Argentina and the Cape of Good Hope (Pritchard 1992). Nesting grounds are distributed circumglobally, with the Pacific Coast of Mexico once supporting the world's largest known concentration of nesting leatherbacks (Pritchard 1982). The largest nesting colonies in the wider Caribbean region are found in Suriname/French Guiana, Trinidad, Costa Rica, Panama, Colombia, and Guyana (NMFS and USFWS 1992; National Research Council 1990; Troëng et al. 2004).

The leatherback is the largest living turtle, and is so distinctive as to be placed in a separate taxonomic family, Dermochelyidae. The carapace is distinguished by a rubber-like texture, about 1.6 inches thick, and made primarily of tough, oil-saturated connective tissue. No sharp angle is formed between the carapace and the plastron, resulting in the animal being somewhat

barrel-shaped. The average curved carapace length for adult turtles is 61 inches and weight ranges from 441 to 1,543 pounds. Hatchlings are mostly black on top and are covered with tiny scales; the flippers are edged in white, and rows of white scales appear as stripes along the length of the back. Hatchlings average 2.4 inches long and 1.6 ounces in weight. In the adult, the skin is black and scaleless. The undersurface is mottled pinkish-white and black. The front flippers are proportionally longer than in any other sea turtle, and may span 106 inches in an adult. In both adults and hatchlings, the upper jaw bears two tooth-like projections (NMFS and USFWS 1992).

The leatherback regularly nests in Puerto Rico, the U.S. Virgin Islands, and along the Atlantic coast of Florida (NMFS and USFWS 1992). Leatherback turtles have been known to nest in Georgia, South Carolina, and North Carolina, but only on rare occasions (Rabon et al. 2003, GDNR 2004). Leatherback nesting also has been reported on the northwest coast of Florida (LeBuff 1990.

The recovery objective for U.S. population of the leatherback turtle include:

> when the adult female population increases over the next 25 years, as evidenced by a statistically significant trend in the number of nests at Culebra, Puerto Rico, St. Croix, U.S. Virgin Islands, and along the east coast of Florida, and nesting habitat encompassing at least 75 percent of nesting activity in the U.S. Virgin Islands, Puerto Rico, and Florida is in public ownership. In addition, all priority one tasks identified in the recovery plan must be successfully implemented (NMFS and USFWS 1992).

Critical habitat has been designated for the leatherback sea turtle in the U.S. Virgin Islands.

B. Life History

Piping plover

Piping plover breeding activity begins in mid-March when birds begin returning to their nesting areas (Coutu et al. 1990, Cross 1990, Goldin et al. 1990, MacIvor 1990, Hake 1993). Males establish and defend territories and court females (Cairns 1982). Piping plovers are monogamous, but usually shift mates between years (Wilcox 1959, Haig and Oring 1988, MacIvor 1990) and less frequently between nesting attempts in a given year (Haig and Oring 1988, MacIvor 1990, Strauss 1990). Plovers may begin breeding as early as one year of age (MacIvor 1990, Haig 1992); however, the percentage of birds that breed in their first adult year is unknown. Observations suggest that this species exhibits a high degree of nest site fidelity (Wilcox 1959, Haig 1985, Haig and Oring 1988).

Piping plover nests can be found above the high tide line on coastal beaches, on sand flats at the ends of sand spits and barrier islands, on gently sloping foredunes, in blowout areas behind primary dunes, and in washover areas cut into or between dunes. The birds may also nest on areas where suitable dredge material has been deposited. Nest sites are shallow, scraped depressions in substrates ranging from fine-grained sand to mixtures of sand and pebbles, shells or cobble (Bent 1929, Burger 1987a, Cairns 1982, Patterson 1988, MacIvor 1990, Strauss 1990, Flemming et al. 1992). Nests are usually found in areas with little or no vegetation; although, on

occasion, piping plovers will nest under stands of American beachgrass or other vegetation (Patterson 1988, MacIvor 1990, Flemming et al. 1992). Plover nests may be very difficult to detect, especially during the 6 to 7 day egg-laying phase when the birds generally do not incubate (Goldin 1994).

Eggs may be present on the beach from early April through late July. Clutch size for an initial nest attempt is usually four eggs, one laid every other day. Eggs are pyriform in shape, and variable buff to greenish brown in color, marked with black or brown spots. The incubation period usually lasts 27 to 28 days. Full-time incubation usually begins with the completion of the clutch and is shared equally by both sexes (Wilcox 1959, Cairns 1977, MacIvor 1990). Eggs in a clutch usually hatch within 4 to 8 hours of each other, although the hatching period of one or more eggs may be delayed by up to 48 hours (Cairns 1977, Wolcott and Wolcott 1999).

Piping plovers generally fledge only a single brood per season, but may renest several times if previous nests are lost. Chicks are precocial (Wilcox 1959, Cairns 1982). They may move hundreds of yards from the nest site during their first week of life (see Table 1 in USFWS 1996), and chicks may increase their foraging range up to 3,000 feet before they fledge (Loegering 1992). Chicks remain together with one or both parents until they fledge at 25 to 35 days of age. Depending on date of hatching, flightless chicks may be present from mid-May until late August, although most fledge by the end of July (Patterson 1988, Goldin et al. 1990, MacIvor 1990, Howard et al. 1993).

Cryptic coloration is a primary defense mechanism for this species; nests, adults, and chicks all blend in with their typical beach surroundings. Chicks sometimes respond to vehicles and/or pedestrians by crouching and remaining motionless (Cairns 1977, Tull 1984, Goldin 1993b, Hoopes 1993). Adult piping plovers also respond to intruders (avian and mammalian) in their territories by displaying a variety of distraction behaviors, including squatting, false brooding, running, and injury feigning. Distraction displays may occur at any time during the breeding season but are most frequent and intense around the time of hatching (Cairns 1977).

Plovers feed on invertebrates such as marine worms, fly larvae, beetles, crustaceans, and mollusks (Bent 1929, Cairns 1977, Nicholls 1989). Important feeding areas include intertidal portions of ocean beaches, washover areas, mudflats, sand flats, wrack lines, sparse vegetation, and shorelines of coastal ponds, lagoons, or salt marshes (Gibbs 1986, Coutu et al. 1990, Hoopes et al. 1992, Loegering 1992, Goldin 1993a, Elias-Gerken 1994). Studies have shown that the relative importance of various feeding habitat types may vary by site (Gibbs 1986, Coutu et al. 1990, McConnaughey et al. 1990, Loegering 1992, Goldin 1993a, Hoopes 1993, Elias-Gerken 1994) and by stage in the breeding cycle (Cross 1990). Adults and chicks on a given site may use different feeding habitats in varying proportion (Goldin et al. 1990). Feeding activities of chicks are particularly important to their survival. Most time budget studies reveal that chicks spend a high proportion of their time feeding. Cairns (1977) found that piping plover chicks typically tripled their weight during the first two weeks post-hatching; chicks that failed to achieve at least 60 percent of this weight gain by the twelfth day were unlikely to survive.

During courtship, nesting, and brood rearing, feeding territories are generally contiguous to nesting territories (Cairns 1977), although instances where brood-rearing areas are widely

separated from nesting territories are common. Feeding activities of both adults and chicks may occur during all hours of the day and night (Staine and Burger 1994), and at all stages in the tidal cycle (Goldin 1993a, Hoopes 1993).

Both spring and fall migration routes of Atlantic Coast breeders are believed to occur primarily within a narrow zone along the Atlantic Coast (USFWS 1996). Some mid-continent breeders travel up or down the Atlantic Coast before or after their overland movements (Stucker and Cuthbert 2006). Use of inland stopovers during migration is also documented (Pompei and Cuthbert 2004). The pattern of both fall and spring counts at many Atlantic Coast sites demonstrates that many piping plovers make intermediate stopovers lasting from a few days up to one month during their migrations (NPS 2003, Noel et al. 2005, Stucker and Cuthbert 2006). In addition, this species exhibits a high degree of both intra- and inter-annual wintering site fidelity (Drake et. al. 2001, Noel et al. 2005, Stucker and Cuthbert 2006).

A growing body of information shows that overwash-created and -perpetuated habitats, including accessible bayside flats, unstabilized and recently healed inlets, and moist sparsely vegetated barrier flats are especially important to piping plover productivity and carrying capacity in the New York-New Jersey and Southern recovery units.

In New Jersey, Burger (1994) studied piping plover foraging behavior and habitat use at three sites that offered the birds: ocean, dune, and backbay habitats. The primary focus of the study was on the effect of human disturbance on habitat selection, and it found that both habitat selection and foraging behavior correlated inversely with the number of people present. In the absence of people on an unstabilized beach, plovers fed in ocean and bayside habitats in preference to the dunes.

Loegering and Fraser (1995) found that chicks on Assateague Island, Maryland that were able to reach bay beaches and the island interior had significantly higher fledgling rates than those that foraged solely on the ocean beach. Higher foraging rates, percentage of time spent foraging, and abundance of terrestrial arthropods on the bay beach and interior island habitats supported their hypothesis that foraging resources in interior and bayside habitats are key to reproductive rates on that site. Their management recommendations stressed the importance of sparsely vegetated cross-island access routes maintained by overwash, and the need to restrict or mitigate activities that reduce natural disturbance during storms.

Dramatic increases in plover productivity and breeding population on Assateague since the 1991-1992 advent of large overwash events corroborate Loegering and Fraser's conclusions. Piping plover productivity, which had averaged 0.77 chicks per pair during the five years before the overwash, averaged 1.67 chicks/pair in 1992-96. The nesting population on the northern five miles of the island also grew rapidly, doubling by 1995 and tripling by 1996, when 61 pairs nested there (MacIvor 1996). Habitat use is primarily on the interior and bayside.

In Virginia, Watts et al. (1996) found that piping plovers nesting on 13 barrier islands between 1986 and 1988 were not evenly distributed along the islands. Beach segments used by plovers had wider and more heterogeneous beaches, fewer stable dunes, greater open access to bayside

foraging areas, and proximity to mudflats. They note that characteristics of beaches selected by plovers are maintained by frequent storm disturbance.

At Cape Lookout National Seashore in North Carolina, 13 to 45 pairs of plovers have nested on North and South Core Banks each year since 1992 (NPS 2007d). While these unstabilized barrier islands total 44 miles long, nesting distribution is patchy, with all nests clustered on the dynamic ends of the barrier islands, recently closed and sparsely vegetated "old inlets," expansive barrier mudflats, or new ocean-to-bay overwashes. During a 1990 study, 96 percent of brood observations were on bay tidal flats, even though broods had access to both bay and ocean beach habitats (McConnaughey et al. 1990).

At CAHA, distribution of nesting piping plovers is also "clumped," with nesting areas characterized by a wide beach, relatively flat intertidal zone, brackish ponds, and temporary pools formed by rainwater and overwash (Coutu et al. 1990).

Notwithstanding the importance of bayside (soundside) flats, ephemeral pools, and sparsely vegetated barrier flats for piping plover nest site selection and chick foraging, ocean intertidal zones are also used by chicks of all ages. For example, between 1993 and 1996 on the Maryland end of Assateague Island, four to 12 percent of annual observations of plover broods occurred on the ocean beach (NPS and Maryland DNR 1993-1996). A three-year study of piping plover chick foraging activity at six sites on four Virginia barrier islands (Cross and Terwilliger 2000) documented chick use of the ocean intertidal zone at three of six study sites. Intensive observations at Chincoteague National Wildlife Refuge Overwash Zone in 2004, where chicks had unimpeded access to a large undisturbed bayside flat, documented occasional visits to the ocean intertidal zone by six of eleven broods ranging in age from one to 24 days (Hecht 2004, *in litt.*).

Wintering and migrating piping plovers on the Atlantic Coast are generally found at the accreting ends of barrier islands, along sandy peninsulas, and near coastal inlets. Wintering piping plovers appear to prefer sand flats adjacent to inlets or passes, sandy mud flats along prograding spits (areas where the land rises with respect to the water level), and overwash areas as foraging habitats. These substrate types may have a richer infauna than the foreshore of high energy beaches and often attract large numbers of shorebirds. Roosting plovers are generally found along inlet and adjacent ocean and estuarine shorelines and their associated berms and on nearby exposed tidal flats (Nicholls and Baldassarre 1990). Since tidal conditions and weather often cause plovers to move among habitat patches, diverse habitat patches may be especially important to plovers and may concentrate wintering piping plovers when roosting and feeding areas are adjacent (Johnson and Baldassarre 1988, Nicholls and Baldassarre 1990, Drake et al. 2001). Wintering plovers with small home ranges which contain safe roosts and abundant food should experience low commuting costs, and would be expected to have higher survival (Drake et al. 2001).

Cohen et al. (in press) conducted a study on wintering piping plovers at and near the Oregon Inlet during the winter of 2005/2006. They found that all plover habitat use fell into one of three habitat zones: ocean beach, sound beach, and sound island (dredged material, shoal, and other marsh and mudflat/sandflat islands). In the study, plovers were more likely to use sound islands

than ocean beach or sound beach when the intertidal area of sound islands was exposed during low tide. Plovers using ocean beach spent less time foraging (18%) than when on sound beaches (88%) and sound islands (83%).

Factors affecting the piping plover during its life cycle

Predation has been identified as a major factor limiting piping plover reproductive success at many Atlantic Coast sites (Burger 1987a, MacIvor 1990, Cross 1991, Patterson et al. 1991, Elias-Gerken, 1994). As with other limiting factors, the nature and severity of predation is highly site specific. Predators of piping plover eggs and chicks include foxes, skunks, raccoons, rats, opossums, crows, gulls, grackles, American kestrels, domestic and feral dogs and cats, and ghost crabs.

Substantial evidence exists that human activities are affecting types, numbers, and activity patterns of predators, thereby exacerbating natural predation. Non-native species such as feral cats and rats are considered significant predators at some sites (Goldin et al. 1990, Post 1991). Humans have also indirectly influenced predator populations by abetting the expansions in the populations and/or range of other species such as gulls (Drury 1973). Strauss (1990) found that the density of fox tracks on a beach area was higher during periods of more intensive human use.

Predation and nest abandonment because of predators have been implicated as a cause of low reproductive success (Cooper 1990, Coutu et al. 1990, Kuklinski et al. 1996). Predator trails (of foxes, dogs, and cats) have been seen around areas of the last known location of piping plover chicks. Predatory birds also are relatively common during their fall and spring migration along the Atlantic Ocean coastline, and there is a possibility they may occasionally take plovers.

Piping plover habitats (breeding and non-breeding) are dependent on natural forces of creation and renewal. However, storms and severe cold weather are believed to take their toll on plovers. After an intense snowstorm swept the entire North Carolina coast in late December 1989, high mortality of many coastal bird species was noted (Fussell 1990). Piping plover numbers decreased significantly from about 30 to 40 birds down to 15 birds. While no dead piping plovers were found, circumstantial evidence suggests that much of the decrease was mortality (Fussell 1990). Hurricanes may also result in direct mortality or habitat loss, and if piping plover numbers are low enough or if total remaining habitat is sparse relative to historical levels, population responses may be impaired even through short-term habitat losses. Wilkinson and Spinks (1994) suggest that, in addition to the unusually harsh December 1989 weather, low plover numbers seen in South Carolina in January 1990 (11 birds, compared with more than 50 during the same time period in 1991 to 1993) may have been influenced by effects on habitat and food availability caused by Hurricane Hugo in September 1989. Hurricane Elena struck the Alabama coast in September 1985 and subsequent surveys noted a reduction of intertidal foraging habitat on Dauphin and Little Dauphin Islands (Johnson and Baldassarre 1988). Birds were observed foraging at Sand Island, a site that was used little prior to the hurricane.

Unrestricted use of motorized vehicles on beaches is a serious threat to piping plovers and their habitats. Vehicles can crush eggs (Wilcox 1959, Tull 1984, Burger 1987b, Patterson et al. 1991, Shaffer and Laporte 1992) as well as adults and chicks. However, the mobility of newly hatched

chicks and adults does not lessen the susceptibility to mortality by vehicles. For example, in Massachusetts and New York, biologists documented 14 incidents in which 18 chicks and two adults were killed by vehicles between 1989 and 1993 (Melvin et al. 1994). Goldin (1993b) compiled records of 34 chick mortalities (30 on the Atlantic Coast and four on the northern Great Plains) due to vehicles. Biologists that monitor and manage piping plovers believe that many more chicks are killed by insufficiently-managed vehicles than are found and reported (Melvin et al. 1994). Beaches used by vehicles during nesting and brood-rearing periods.generally have fewer breeding plovers than available nesting and feeding habitat can support. In contrast, plover abundance and productivity has increased on beaches where vehicle restrictions during chick-rearing periods have been combined with protection of nests from predators (Goldin 1993b).

Typical behaviors of piping plover chicks increase their vulnerability to vehicles. Chicks frequently move between the upper berm or foredune and feeding habitats in the wrack line and intertidal zone. These movements place chicks in the paths of vehicles driving along the berm or through the intertidal zone. Chicks stand in, walk, and run along tire ruts, and sometimes have difficulty crossing deep ruts or climbing out of them (Strauss 1990, Eddings 1991, Howard et al. 1993). Chicks sometimes stand motionless or crouch as vehicles pass by, or do not move quickly enough to get out of the way (Tull 1984, Hoopes et al. 1992, Goldin 1993b).

Vehicles also significantly degrade piping plover habitat or disrupt normal behavior patterns. They may harm or harass plovers by crushing wrack into the sand and making it unavailable as cover or a foraging substrate (Hoopes et al. 1992, Goldin 1993b), by creating ruts that can trap or impede movements of chicks (Jacobs 1988, *in litt.*), and by preventing plovers from using habitat that is otherwise suitable (MacIvor 1990, Strauss 1990, Hoopes et al. 1992, Goldin 1993b, Hoopes 1994). Zonick (2000) found that ORV density negatively correlated with abundance of roosting, nonbreeding plovers on the ocean beach in Texas. Studies elsewhere (e.g. Wheeler 1979) demonstrate adverse effects of ORV driving on soundside beaches on the abundance of infauna essential to piping plover foraging requirements.

Lighting may also negatively affect piping plovers. While the extent that artificial lighting (including vehicle lights) affects piping plovers is unknown, there is evidence that American oystercatcher (*Haematopus palliatus*) chicks and adults are attracted to vehicle headlights and may move toward areas of ORV activity. During a 2005 study at Cape Lookout National Seashore, adult and chick oystercatchers were observed running or flying directly into the headlights of oncoming vehicles, and two two-day old oystercatcher chicks were run over by an all-terrain vehicle after being observed foraging with the adults near the high tide line at night (Simons et al. 2005).

Pedestrian and non-motorized recreational activities can be a source of both direct mortality and harassment of piping plovers. There are a number of potential sources for pedestrians on the beach, including those individuals driving and subsequently parking on the beach, those originating from off-beach parking areas (hotels, motels, commercial facilities, beachside parks, etc.), and those from beachfront and nearby residences.

Pedestrians on beaches may crush eggs (Burger 1987b, Shaffer and Laporte 1992, NPS 1993), or flush plovers from nests exposing their eggs to predators. Concentrations of pedestrians may also deter piping plovers from using otherwise suitable habitat. Ninety-five percent of Massachusetts plovers (n = 209) observed by Hoopes (1993) were found in areas that contained less than one person per 2 acres of beach. Elias-Gerken (1994) found that piping plovers on Jones Beach Island, New York, selected beachfront that had less pedestrian disturbance. Sections of beach at Trustom Pond National Wildlife Refuge in Rhode Island were colonized by piping plovers within two seasons of their closure to heavy pedestrian recreation. Burger (1991, 1994) found that the presence of people at several New Jersey sites caused plovers to shift their habitat use away from the ocean front to interior and bayside habitats; the time plovers devoted to foraging decreased and the time spent alert increased when more people were present. Burger (1991) also found that when plover chicks and adults were exposed to the same number of people, the chicks spent less time foraging and more time crouching, running away from people, and being alert than did the adults.

Pedestrians may flush incubating plovers from nests, exposing eggs to excessive temperatures. Repeated exposure of shorebird eggs on hot days may cause overheating, killing the embryos (Bergstrom 1989); excessive cooling may kill embryos or retard their development, delaying hatching dates (Welty 1982). Pedestrians can also displace unfledged chicks (Strauss 1990, Burger 1991, Hoopes et al. 1992, Loegering 1992, Goldin 1993b), forcing them out of preferred habitats, decreasing available foraging time, and causing expenditure of energy.

Fireworks are highly disturbing to piping plovers (Howard et al. 1993). Plovers are also intolerant of kites, particularly as compared to pedestrians, dogs, and vehicles; biologists believe this may be because plovers perceive kites as potential avian predators (Hoopes et al. 1992).

Noncompliant pet owners who allow their dogs off leash have the potential to flush piping plovers and these flushing events may be more prolonged than those associated with pedestrians or pedestrians with dogs on leash. Unleashed dogs may chase plovers (McConnaughey et al. 1990), destroy nests (Hoopes et al. 1992), and kill chicks (Cairns and McLaren 1980, Boyagian 1994, *in litt.*).

Demographic models for piping plovers indicate that even small declines in adult and juvenile survival rates will cause very substantial increases in extinction risk (Melvin and Gibbs 1994, Larson et al. 2000, Wemmer et al. 2001, Calvert et al. 2006). Furthermore, insufficient protection of non-breeding piping plovers has the potential to quickly undermine the progress toward recovery achieved at breeding sites. For example, a banding study conducted between 1998 and 2004 in Atlantic Canada found lower return rates of juvenile (first year) birds to the breeding grounds than was documented for Massachusetts (Melvin and Gibbs 1994), Maryland (Loegering 1992), and Virginia (Cross 1996) breeding populations in the mid-1980s and very early 1990s. This is consistent with failure of the Atlantic Canada population to increase abundance despite very high productivity (relative to other breeding populations) and extremely low rates of dispersal to the U.S. (Calvert et al. 2006). This suggests that maximizing productivity does not ensure population increases; management must focus simultaneously on all sources of stress on the population within management control.

Loggerhead sea turtle

Loggerheads are known to nest on average about four times within a nesting season, ranging from one to seven times (Talbert et al. 1980, Lenarz et al. 1981, Richardson and Richardson 1982, Murphy and Hopkins 1984). The interval between nesting varies around a mean of about 14 days (Dodd 1988). Mean clutch size varies from about 100 to 126 eggs per nest along the southeastern U.S. coast (NMFS and USFWS 1991b). The loggerhead returns at intervals of two to three years, but the number can vary from one to seven years (Dodd 1988). Age at sexual maturity is likely to be greater than 30 years (Snover 2002).

Green sea turtle

Green turtles deposit from one to nine clutches within a nesting season, but the overall average is about 3.3. The interval between nesting varies around a mean of about 13 days (Hirth 1997). Mean clutch size varies widely among populations. Average clutch size reported for Florida was 136 eggs in 130 clutches (Witherington and Ehrhart 1989). Only occasionally do females produce clutches in successive years. Usually two to four years intervene between breeding seasons (NMFS and USFWS 1991a). Age at sexual maturity is believed to be 20 to 50 years (Hirth 1997).

Leatherback sea turtle

Leatherbacks nest an average of five to seven times within a nesting season, with an observed maximum of 11 (NMFS and USFWS 1992). The interval between nesting is about nine to ten days. Clutch size averages 101 eggs on Hutchinson Island, Florida (Martin 1992). Most leatherbacks return at two to three-year intervals based on data from the Sandy Point National Wildlife Refuge, St. Croix, U.S. Virgin Islands (McDonald and Dutton 1996). Leatherbacks are believed to reach sexual maturity in six to ten years (Zug and Parham 1996).

Factors affecting sea turtles during portions of their life cycle

Artificial lighting is one of the most significant impacts on sea turtle survival, especially of post-emergent hatchlings (Mann 1977, Ehrhart and Witherington 1987, Witherington 1992). Visual cues are the primary sea-finding mechanism for hatchlings (Mrosovsky and Carr 1967, Mrosovsky and Shettleworth 1968, Dickerson and Nelson 1989, Witherington and Bjorndal 1991). Hatchlings show a tropotactic response to light upon emergence, so any visual stimulus in the field of vision has some effect on the direction chosen by the hatchlings (Mrosovsky 1970). Hatchlings instinctively orient to the brightest horizon, which, in the absence of artificial lights, is usually the ocean horizon. It is possible to attract hatchlings out of the surf with a bright light, demonstrating the importance of light stimulus in hatchling behavior (Carr and Ogren 1960, Ehrhart and Witherington 1987).

Artificial lighting cues can cause misorientation (hatchlings travel along a consistent course toward a light source) or disorientation (hatchlings are not able to set a particular course and wander aimlessly) (Philibosian 1976, Mann 1977, Witherington 1990). Hatchlings are frequently attracted to point source lights on buildings and roadways in urban areas (McFarlane

1963, Philibosian 1976, Mann 1978, Witherington 1992). Urban areas may also have a non-point source nighttime glow which may disorient hatchlings from otherwise dark sections of beach (Witherington 1993, Tuxbury and Salmon 2005). Light intensities from sky measurements taken on the beach can be higher than the ocean horizon (Salmon et al. 1995a).

Once disoriented, turtles often enter conflicting light environments as they head landward. As hatchlings approach buildings and roads, they encounter obstacles that may screen the source of artificial light (Salmon et al. 1995b). They may then re-orient themselves correctly toward the ocean or continue along the obstruction (e.g. seawall, deep ruts, buildings) until they can see the original or perhaps another source of artificial light. If the obstructions are high enough and continuous enough to prevent the hatchlings from leaving the beach, the lightening sky as sunrise approaches often becomes a dominant influence and attracts the hatchlings to the surf. Mann (1977) also found that most turtles in artificial light-dominated areas oriented correctly on brightly moonlit nights. On moonless nights, hatchlings were more easily disoriented by artificial lights.

The correlation between level of light-caused disruption and survivorship has not, however, been identified. It has been demonstrated that there are relative degrees of sub-lethal and lethal effects, ranging from mild misorientation of a few hatchlings to strong disorientation of a whole clutch resulting in mortality for many hatchlings (Salmon et al. 1995a, Witherington et al. 1996).

Both Mann (1977) and Ehrhart and Witherington (1987) found high mortality in the emergences where the majority of the hatchlings were strongly disoriented. If the hatchlings do not manage to enter the surf, they may enter the vehicle corridor where they are subject to being run over, trapped in tire ruts and become vulnerable to predators, or become irretrievably lost from finding their way to the surf. The protracted wanderings of disoriented hatchlings also lengthens the time they are susceptible to predation from raccoons, ghost crabs, seabirds, fish crows, night herons and possibly dogs and cats. The prolonged exposure can exhaust and/or dehydrate the turtles to the point of death or limit their chance of survival once in the water. Weakened hatchlings that eventually reach the water may be more vulnerable to marine predators, which are abundant in nearshore waters (Wyneken et al. 1994).

Research has also documented significant reduction in sea turtle nesting activity on beaches illuminated with artificial lights (Witherington 1992). Lights may deter females from coming ashore to nest or disorient females trying to return to the surf after a nesting event. However, artificial lighting does not appear to be as problematic for nesting adult female sea turtles as compared to hatchlings. They seem to use a straight-ahead method to select a nest site. They do not appear to be affected as much by artificial lights along the beach as they are by bright lights immediately in front of them upon emerging from the surf (Salmon et al. 1995b, Witherington 1992). Distant point sources and urban glow are more likely to affect hatchlings than adult females (Salmon et al. 1995b). The effects of lights on the female's decision of where to emerge remain unknown.

Hurricanes and other storms during late summer and fall on the east coast of the U.S. create conditions that often result in beach erosion and the subsequent loss of sea turtle nests. Nests may be washed out or inundated long enough to result in egg mortality. In the last several years,

numerous hurricanes and tropical storms have resulted in substantial impacts to the coastal environment along most of the eastern United States. Erosion resulted in a reduction of beach profile in some areas and an accretion of sand in others. High tides and storm surges from these tropical systems overwashed, washed out, buried, or inundated sea turtle nests. Due to nesting chronology, most of the nests lost to storm events will be loggerhead and a few green sea turtle nests. Leatherback sea turtles typically nest earlier in the season and most, if not all, nests have hatched prior to the peak of the tropical storm season.

The use of ORVs on sea turtle nesting beaches can adversely affect the egg, hatchling, and nesting life stages of sea turtles. Vehicles can directly impact sea turtles by running over nesting females and hatchlings making their way to the ocean; crushing nests; deterring females from nesting and approaching nesting beaches; and changing the beach profile and nesting habitat (e.g., compacting sand and making nest excavation difficult, producing ruts in the sand that trap hatchlings, and creating escarpments that prevent females from accessing the beach). Vehicles on beaches, especially during night hours, run the risk of striking adult females emerging on the beach to nest or hatchlings making their way towards the surf after emerging from the nest (National Research Council 1990).

Driving on dune systems alters beach habitat for turtle nesting. Vehicles change the character of the beach profile (Hosier and Eaton 1980), thus increasing the chance of unsuitable nesting habitat for turtles and reducing the number of nests laid and/or hatchlings produced. Erosion can increase in areas with vehicular traffic (National Research Council 1990), which can create escarpments that prevent females from reaching the nesting area of the beach or act as obstacles to hatchlings trying to reach the ocean.

Ruts caused by ORVs reduce the number of hatchlings that make it to the ocean (Lamont et al. 2002). The ruts act as barriers which trap hatchlings making them prone to desiccation and predation. Live and desiccated turtles have been observed in deep vehicle ruts (LeBuff 1990). The ruts can also act as pathways, leading hatchlings away from the ocean. Apparently, hatchlings become diverted not necessarily because they cannot physically climb out of the rut (Arianoutsou 1988, Hughes and Caine 1994), but because the sides of the track cast a shadow and the hatchlings lose their line of sight to the ocean horizon (Mann 1977). If hatchlings are detoured along vehicle ruts, they are at greater risk to vehicles, predators, fatigue, and desiccation. However, hatchling turtles also have a greater probability of overturning when they have to maneuver over ruts in the sand (Hosier 1981; Hosier et al. 1981), which can expose them to desiccation and predation. At least two studies have confirmed hatchling disorientation by vehicular ruts (Cox et al. 1994, Hosier et al. 1981).

Sand compaction resulting from ORVs may increase the length of time required for female sea turtles to excavate nests. If sediments become too compacted, a female turtle may have difficulty excavating an egg chamber of adequate depth or dimensions (Raymond 1984, Ryder 1990, Carthy 1994). Compression of sand by vehicles also causes reduced hatching success of loggerhead turtle nests (Mann 1977). Nesting areas with vehicle traffic have a lower hatchling emergence due to egg chamber cave-ins, making it harder for hatched turtles to emerge to the surface (Mann 1977). Mortality while hatching out of eggs is also higher on beaches open to public access than beaches with restricted access (Kudo et. al. 2003).

Pedestrian traffic on the beach can have a wide variety of adverse affects on sea turtles. People often walk on beaches at night seeking encounters with nesting female sea turtles. These interactions can interfere with the successful excavation of a nest chamber and/or deposition of eggs and may result in abandonment of nesting attempts (McFarlane 1963, Johnson et al. 1996). Once a turtle leaves the beach, she may return to the same location or select a new site later that night or the following night. However, repeated interruption of nesting may cause a turtle to construct her nest in a sub-optimal incubation environment, postpone nesting for several days, prompt movement many miles from the original chosen nesting site, or cause the turtle to shed her eggs at sea (Murphy 1985). Studies of pedestrian impacts on loggerhead sea turtle nests in Japan have shown that beaches with full pedestrian access have significantly lower emergence success, compared to nests laid on beaches with restricted pedestrian access (Kudo et al. 2003). The full extent to which nighttime beach use by humans may affect sea turtles is not known.

Increased pedestrian use increases the amount of trash left behind on the beach. This waste becomes a threat to hatchlings and adult turtles on the beach and in the water. Sea turtles ingest waste products, especially plastics, due to their resemblance to jellyfish, a turtle food source (National Research Council 1990). Bugoni et al. (2001) found as much as 60 percent of the turtles investigated had ingested marine debris. Beach trash can also impede the movement of hatchlings to the ocean.

Dogs running freely on beaches have been identified as potential predators of eggs, hatchlings and even adult sea turtles (Dodd 1988, Santos and Godfrey 2001).

C. Population dynamics

Piping plover

Great Lakes Population

The Great Lakes plovers once nested on Great Lakes beaches in Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, Wisconsin, and Ontario. Russell (1983) reviewed historical records to estimate the pre-settlement populations of the plover throughout this range. While estimates may be high for some Great Lakes states, no other historic estimates are available. Total population estimates ranged from 492 to 682 breeding pairs in the Great Lakes region; Michigan alone may have had the most with as many as 215 pairs. When listed, the Great Lakes population numbered only 17 known breeding pairs that nested in northern Michigan. Gradual increases in this population have been documented since listing and these birds are now known to have expanded to the south and west (USFWS 2003). Twenty-nine breeding pairs were observed in 2001 (Ferland and Haig 2002). As of 2007, there were an estimated 63 nesting pairs (Dingledine 2008, *in litt.*).

Great Lakes piping plovers nest on wide, flat, open, sandy or cobble shoreline with very little grass or other vegetation. Reproduction is adversely affected by human disturbance of nesting areas and predation by foxes, gulls, crows and other avian species. Shoreline development, such

as the construction of marinas, breakwaters, and other navigation structures, has adversely affected nesting and brood rearing.

Northern Great Plains Population

The Northern Great Plains plover breeds from Alberta to Manitoba, Canada and south to Nebraska; although some nesting has recently occurred in Oklahoma. Currently the most westerly breeding piping plovers in the United States occur in Montana and Colorado.

Nesting occurs on sand flats or bare shorelines of rivers and lakes, including sandbar islands in the upper Missouri River system, and patches of sand, gravel, or pebbly-mud on the alkali lakes of the northern Great Plains. Breeding surveys in the early 1980s reported 2,137 to 2,684 adult plovers in the northern Great Plains/Prairie region (Haig and Oring 1985). In 1991, 2,032 adult plovers were observed in the U.S. portion of the northern Great Plains (Haig and Plissner 1993). The number declined to 1,599 in 1996 (Plissner and Haig 1997), a reduction of 21 percent from 1991. Part of this reduction may be an artifact of increased numbers of plovers nesting in Canada in 1996 due to high water levels in the U.S. (Plissner and Haig 1997). Overall in both the U.S. and Canadian portion of the northern Great Plains, 3,469 adult piping plovers were observed in 1991; 3,286 were observed in 1996; and 2,953 were observed in 2001 (Ferland and Haig 2002). The 2001 figure includes 1,291 breeding pairs.

The decline of piping plovers on rivers in the Northern Great Plains has been largely attributed to the loss of sandbar island habitat and forage base due to dam construction and operation. While piping plovers do nest on shorelines of reservoirs created by the dams, reproductive success is often low and reservoir habitat is not available in many years due to high water levels or vegetation. Dams operated with steady constant flows allow vegetation to grow on potential nesting islands, making these sites unsuitable for nesting. Population declines in alkali wetlands are attributed to wetland drainage, contaminants, and predation.

Atlantic Coast Population

The Atlantic Coast piping plover breeds on coastal beaches from Newfoundland and southeastern Quebec to North Carolina. Historical population trends for the Atlantic Coast piping plover have been reconstructed from scattered, largely qualitative records. Nineteenth-century naturalists, such as Audubon and Wilson, described the piping plover as a common summer resident on Atlantic Coast beaches (Haig and Oring 1987). However, by the beginning of the 20th Century, egg collecting and uncontrolled hunting, primarily for the millinery trade, had greatly reduced the population, and in some areas along the Atlantic Coast, the piping plover was close to extirpation. Following passage of the Migratory Bird Treaty Act (40 Stat. 775; 16 U.S.C. 703-712) in 1918, and changes in the fashion industry that no longer exploited wild birds for feathers, piping plover numbers recovered to some extent (Haig and Oring 1985).

Available data suggest that the most recent population decline began in the late 1940s or early 1950s (Haig and Oring 1985). Reports of local or statewide declines between 1950 and 1985 are numerous, and many are summarized by Cairns and McLaren (1980) and Haig and Oring (1985). While Wilcox (1939) estimated more than 500 pairs of piping plovers on Long Island, New

York, the 1989 population estimate was 191 pairs (see Table 4, USFWS 1996). There was little focus on gathering quantitative data on piping plovers in Massachusetts through the late 1960s because the species was commonly observed and presumed to be secure. However, numbers of piping plover breeding pairs declined 50 to 100 percent at seven Massachusetts sites between the early 1970s and 1984 (Griffin and Melvin 1984). Piping plover surveys in the early years of the recovery effort found that counts of these cryptically colored birds sometimes went up with increased census effort, suggesting that some historic counts of piping plovers by one or a few observers may have underestimated the piping plover population. Thus, the magnitude of the species decline may have been more severe than available numbers imply.

The Atlantic Coast population has increased from 790 pairs since listing to a preliminary estimate of 1,887 pairs in 2007 (USFWS 2008a)(final 2006 estimate of 1,749 pairs, USFWS 2006b). Population growth has been greatest in the New England and New York-New Jersey recovery units, with a more modest and recent increase in the Southern unit and an even smaller increase in Atlantic Canada. Periodic rapid declines in abundance of breeding pairs at the level of the recovery unit, including a 68 percent decline in the southern half of the Virginia barrier island chain and North Carolina between 1995 and 2001, illustrate continued population vulnerability. As of 2007, the Southern recovery unit had 333 nesting pairs (USFWS 2008a). The abundance objectives for the Atlantic Coast population and the Southern recovery unit are 2,000 and 400 breeding pairs, respectively, and must be sustained for five years (USFWS 1996).

Species as a whole

The 2001 International Piping Plover Breeding Census resulted in 2,747 breeding pairs distributed across all three breeding populations (Ferland and Haig 2002). Total population numbers have fluctuated over time with some areas experiencing increases and others decreases.

Loggerhead sea turtle

From 1989 to 1998, total estimated loggerhead nesting in the southeastern U.S. ranged from approximately 53,000 to 92,000 nests per year, with well over 90% of the nests occurring in Florida (Turtle Expert Working Group 2000). In 1998, 85,988 nests were documented in Florida alone. However, that number had declined to 49,776 nests in 2006 (FFWCC 2006a). An analysis of nesting data from the Florida Index Nesting Beach Survey (INBS) Program from 1989 to 2007, a more consistent and accurate index survey that includes a subset of the total Florida beach length, showed an overall decrease in loggerhead nesting of 37% (FFWCC 2007).

Standardized monitoring of nearly all ocean-facing beaches in North Carolina was implemented in the mid-1990s. Data collected to date on annual numbers of nests in North Carolina are insufficient to detect a trend. An analysis of a longer-term dataset available for several nesting beaches in the southern reach of North Carolina showed that there was no increasing or decreasing trend in annual nest numbers (Hawkes et al. 2005). Additional, long-term nesting data are needed to determine whether current declines in nesting are part of the inherent variability in sea turtle nesting patterns or the result of other factors.

From a global perspective, the southeastern U.S. nesting aggregation is of importance to the survival of the species and is second in size only to that which nests on islands in the Arabian Sea off Oman (Ross 1982, Ehrhart 1989, NMFS and USFWS 1991b). The status of the Oman loggerhead nesting population, reported to be the largest in the world (Ross 1979), is uncertain because of the lack of long-term standardized nesting or foraging ground surveys and its vulnerability to increasing development pressures near major nesting beaches and threats from fisheries interactions on foraging grounds and migration routes (Possardt 2005, *in litt.*). The loggerhead nesting aggregations in Oman, the southeastern U.S., and Australia have been estimated to account for about 88 percent of nesting worldwide (NMFS and USFWS 1991b).

Green sea turtle

Based on an analysis of 46 green turtle nesting concentrations worldwide, approximately 109,000 to 151,000 females nest annually (NMFS and USFWS 2007a). However, this is a crude estimate since not all nesting sites are included, and some data are not fully verifiable. Since 1989, approximately 579 to 9,642 green turtles have annually nested in Florida, with the all-time high number occurring in 2005 (FFWCC 2006a). Green turtles sporadically nest in North Carolina, South Carolina and Georgia in small numbers. In 2007, 15 green turtles nests were observed in North Carolina (SCDNR 2007). In the U.S. Pacific, over 90 percent of nesting throughout the Hawaiian archipelago occurs at the French Frigate Shoals, where about 200 to 700 females nest each year (NMFS and USFWS 1998). Elsewhere in the U.S. Pacific, nesting takes place at scattered locations in the Commonwealth of the Northern Marianas, Guam, and American Samoa. In the western Pacific, the largest green turtle nesting aggregation in the world occurs on Raine Island, Australia, where tens of thousands of females nest nightly in an average nesting season (Limpus et al. 1993). In the Indian Ocean, major nesting beaches occur in Oman where 30,000 females are reported to nest annually (Ross and Barwani 1995).

Leatherback sea turtle

Pritchard (1982) estimated 115,000 female leatherback turtles worldwide, of which 60% nested along the Pacific coast of Mexico. Spotila et al. (1996) later estimated that only 34,500 females (with confidence limits of 26,200 to 42,900) remained worldwide. The most recent population size estimate for North America alone is from 34,000 to 94,000 adult leatherbacks (Turtle Expert Working Group 2007). A dramatic drop in nesting numbers has been recorded on major nesting beaches along the Pacific Ocean, although a sizeable nesting population exists in Papua-Indonesia (Dutton et al. 2007, Hitipeuw et al. 2007). Severe declines in leatherback nesting have occurred over the last two decades along the Pacific coasts of Mexico and Costa Rica (Spotila et al. 2000). The Pacific Mexican leatherback nesting population, once considered to be the world's largest leatherback nesting population (historically estimated to be 65 percent of worldwide population), is now less than one percent of its estimated size in 1980 (Pritchard 1982, Sarti Martinez et al. 2007). The Malaysian nesting population has collapsed and is near extirpation (Chan and Liew 1996). In the Atlantic Ocean, overall, there appears to be an increasing or stable population trend in all regions except the Western Caribbean and West Africa (for the latter, no long-term data are available)(Turtle Expert Working Group 2007).

The largest nesting populations at present occur in the western Atlantic Ocean in Trinidad and Suriname/French Guiana (4,500 to 7,500 females nesting/year) and in the eastern Atlantic Ocean in Gabon (Billes et al. 2000). In the U.S., most nesting occurs in Florida, U.S. Virgin Islands and Puerto Rico. From 1989 to 2006, 98 to 935 nests were observed in Florida (FFWCC 2006a). An analysis of the Florida Index Nesting Beach Survey shows an overall increase in leatherback nesting from 1989 to 2006 (FFWCC 2007). The U.S. Virgin Islands and Puerto Rico nesting populations also appear to be increasing (Dutton et al. 2005, Turtle Expert Working Group 2007). Leatherback nesting is low in number and sporadic in North Carolina. In 2007, 10 leatherbacks nested in North Carolina (SCDNR 2007)

D. Status and distribution

Piping plover

Populations of piping plovers have declined from historic numbers. Unregulated hunting drove plovers to near extinction in the early 1900s, but protective legislation resulted in population recovery by the mid-1920s. However, piping plover numbers declined again in the 1940s and 1950s due to shoreline development. River flow alteration, channelization, and reservoir construction also contributed to declines during this period.

The endangered Great Lakes population is at a low level. From an all-time low of 12 nesting pairs in 1990, the population has increased to an estimated 63 nesting pairs in 2007 (Dingledine 2008, *in litt.*). During this period most nesting occurred in Michigan, but recently, as many as five pairs have nested along the Lake Superior shoreline in Wisconsin. Also, in 2007 the first successful nesting pair in over 30 years was recorded in the Great Lakes region of Ontario, Canada (Dingledine 2008, *in litt.*).

The Northern Great Plains breeding population continues to decline. Overall, there were an estimated 1,291 northern Great Plains nesting pairs in the U.S. and Canada in 2001. Current estimates of piping plover survival rates are limited, but most mortality was thought to occur during migration or on wintering grounds (Root et al. 1992). The decline of this population has been attributed to the construction of reservoirs that result in the loss of sandbar habitat.

The Atlantic Coast breeding population has experienced an overall increase since listing, but these increases are regionally variable with some areas continuing to experience periodic population declines (USFWS 2008b). The Atlantic Coast population of piping plovers has increased from 790 nesting pairs in 1986 to a preliminary estimate of 1,887 nesting pairs in 2007 (USFWS 2008a). However, the increase is unevenly distributed (with most pairs occurring in New England and New York-New Jersey). Growth of the Atlantic Coast population has followed intensive, expensive, and sustained protection of breeding pairs by USFWS, Canadian Wildlife Service, state, and provincial wildlife agencies; federal, state, municipal, and private landowners; non-government organizations, academic organizations, and interested individuals.

Much of the plover's historic habitat along the Atlantic Coast has already been destroyed or permanently degraded by development and human use. The construction of houses and commercial buildings on and adjacent to barrier beaches directly removes plover habitat and

results in increased human disturbance. Additional disturbance comes in the form of recreational use of beach habitats. While legal restrictions on coastal development may slow the future pace of physical habitat destruction, the trend in habitat availability for this species is inexorably downward. Furthermore, habitat availability for the species is compromised by the ever increasing human access to, and recreational use of, these coastal habitats. The decrease in habitat availability, especially with regard to the dynamic nature of these coastal areas, may force birds to nest in suboptimal habitats, the effects of which could manifest itself in poor future reproductive success.

The decrease in the functional suitability of the plover's habitat due to accelerating recreational activity on the Atlantic Coast may impact productivity. Functional habitat loss occurs when suitable nesting sites are made unusable because high human and/or animal use precludes the birds from successfully nesting. Population growth along both the U.S. and Canadian coasts fosters an ever increasing demand for beach recreation. In 2004, about 30 percent of the U.S. Atlantic Coast population of piping plovers nested on federally owned beaches where some protection is afforded under section 7 of the ESA. The remaining 70 percent of the birds nested on state, town, or privately-owned beaches where plover managers are implementing protections in the face of increasing disturbance from recreation and development. Unfortunately for the piping plover, recreational activities and public use of federally owned beaches have also increased. Pressure on Atlantic Coast beach habitat from development and human disturbance continues (USFWS 1996).

Piping plovers winter in coastal areas of the U.S. from North Carolina to Texas and in portions of Mexico and the Caribbean. Birds from the three breeding populations overlap in their use of wintering habitat. In 2001, 2,389 piping plovers, accounting for approximately 40 percent of the known breeding birds recorded during a breeding census were located during a winter census (Haig et al. 2005). While only 16 percent of all nonbreeding birds counted during the 2001 census were found on the Atlantic Coast, observations of banded migrating and wintering piping plovers from the Great Lakes and Atlantic Canada breeding populations were heavily concentrated on the southern U.S. Atlantic Coast (Amirault et al. 2005, Stucker and Cuthbert 2006). The status of wintering piping plovers is difficult to assess, but threats to piping plover wintering habitat identified by the USFWS during its designation of critical habitat continue to affect the species. Unregulated motorized and pedestrian recreational use, inlet and shoreline stabilization projects, beach maintenance and nourishment, and pollution affect most wintering areas. Conservation efforts at some locations have likely resulted in the enhancement of wintering habitat.

We are aware of the following site-specific conditions that affect the status of several wintering piping plover habitats, including critical habitat units. In Texas, one critical habitat unit was afforded greater protection due to the acquisition of adjacent upland properties by the local Audubon chapter. In another unit in Texas, vehicles were removed from a portion of the beach, thus decreasing the likelihood of automobile disturbance to plovers. In Florida, land acquisition has been initiated within portions of one critical habitat unit in the panhandle. The USFWS remains in a contractual agreement with the U.S. Department of Agriculture for predator control within limited coastal areas in the panhandle, including portions of some critical habitat units. Continued removal of potential terrestrial predators is likely to enhance survivorship of wintering

piping plovers. In North Carolina, one critical habitat unit was afforded greater protection when the local Audubon chapter agreed to manage the area specifically for piping plovers and other shorebirds following the relocation of the nearby inlet channel.

Loggerhead sea turtle

Genetic research involving analysis of mitochondrial DNA has identified five different loggerhead subpopulations/nesting aggregations in the western North Atlantic:

- Northern subpopulation occurring from North Carolina to around Cape Canaveral, Florida (about 29° N.);
- South Florida subpopulation occurring from about 29° N on Florida's east coast to Sarasota on Florida's west coast;
- Dry Tortugas, Florida, subpopulation;
- Northwest Florida subpopulation occurring at Eglin Air Force Base and the beaches near Panama City; and
- Yucatán subpopulation occurring on the eastern Yucatán Peninsula, Mexico.

These data indicate that maternally based gene flow between these five regions is very low. If nesting females are extirpated from one of these regions, regional dispersal will not be sufficient to rapidly replenish the depleted nesting subpopulation (Bowen 1995, *in litt*; Bowen et al. 1993; Encalada et al. 1998; Pearce 2001).

The Northern subpopulation has declined substantially since the early 1970s. Standardized ground surveys of 11 North Carolina, South Carolina and Georgia nesting beaches showed a significant declining trend of 1.9% annually from 1983 to 2005 (NMFS and USFWS 2007b). Nest totals from aerial surveys conducted by the South Carolina Department of Natural Resources showed a 3.1% annual decline from 1980 to 2002 (NMFS and USFWS 2007b). Although long-term data are not available for all beaches in North Carolina, an analysis of annual nest totals on beaches in the southern part of NC showed no discernable increasing or decreasing trend (Hawkes et al. 2005).

An analysis of nesting data from the Florida Index Nesting Beach Survey (INBS) Program from 1989 to 2007 showed an overall decrease in loggerhead nesting of 37% (FFWCC 2007). The Florida Panhandle subpopulation shows a significant declining trend of 6.8% annually from 1995 to 2005 (NMFS and USFWS 2007b).

Current threats include loss or degradation of nesting habitat from coastal development and beach armoring; confusion of hatchlings by beachfront lighting; excessive nest predation by native and non-native predators; degradation of foraging habitat; marine pollution and debris; watercraft strikes; disease; and incidental take from channel dredging and commercial trawling, longline, and gill net fisheries. There is particular concern about the extensive incidental take of juvenile loggerheads in the eastern Atlantic by longline fishing vessels from several countries (Lutcavage et al. 1997, Lewison et al. 2004).

Green sea turtle

Total population estimates for the green turtle are unavailable, and trends based on nesting data are difficult to assess because of large annual fluctuations in numbers of nesting females. Some nesting localities appear to be stable or increasing, while others appear to be declining. Trend data are unavailable for many locations (NMFS and USFWS 2007a). The endangered Florida nesting population appears to have increased from 1989 to 2006. This may partially be due to increased protections through state legislation in Florida (NMFS and USFWS 2007a).

A major factor contributing to the green turtle's decline worldwide has been commercial harvest for eggs and food. Fibropapillomatosis, a disease of sea turtles characterized by the development of multiple tumors on the skin and internal organs, is also a mortality factor and has seriously impacted green turtle populations in Florida, Brazil, Hawaii, and other parts of the world. The tumors interfere with swimming, eating, breathing, vision, and reproduction. Heavy tumor burdens are fatal to the turtles (Herbst 1994). Other threats include loss or degradation of nesting habitat from coastal development and beach armoring; confusion of hatchlings by beachfront lighting; excessive nest predation by native and non-native predators; degradation of foraging habitat; marine pollution and debris; watercraft strikes; and incidental take from channel dredging and commercial fishing operations (Lutcavage et al. 1997).

Leatherback sea turtle

Leatherbacks are less common in the Indian Ocean and in very low numbers in the western Pacific Ocean. The East Pacific and Malaysia leatherback populations have collapsed. Using an age-based demographic model, Spotila et al. (1996) determined that leatherback populations in the Indian Ocean and western Pacific Ocean cannot withstand even moderate levels of adult mortality. They concluded that leatherbacks are on the road to extinction and further population declines can be expected unless action is taken to reduce adult mortality and increase survival of eggs and hatchlings. The largest populations are in the Atlantic Ocean, in Suriname/French Guiana, Gabon, Trinidad and Costa Rica/Panama (Troëng et al. 2004). The North Atlantic population is estimated at 34,000 to 94,000 adults (Turtle Expert Working Group 2007) and appears stable.

The crash of the Pacific leatherback population is believed primarily to be the result of exploitation by humans for the eggs and meat, as well as incidental take in numerous commercial fisheries of the Pacific (Chan and Liew 1996, Spotila et al. 2000). Other factors threatening leatherbacks globally include loss or degradation of nesting habitat from coastal development, confusion of hatchlings by beachfront lighting, excessive nest predation by native and non-native predators, degradation of foraging habitat, marine pollution and debris, and watercraft strikes (Lutcavage et al. 1997).

E. Analysis of the species/critical habitat likely to be affected

Piping plovers

Piping plovers from the Atlantic Coast population are the focus of these biological and conference opinions when referencing breeding birds. Since recovery units have been established in an approved recovery plan for the piping plover (USFWS 1996), these biological and conference opinions will also consider the effects of the proposed project on plovers in the Southern recovery unit. Piping plovers from all three breeding populations are referenced when discussing effects of the proposed action on migrating and wintering plovers. The proposed action has the potential to adversely affect nesting and non-nesting adults, eggs, chicks, and juveniles during the nesting season, and adults and juveniles during the migrating and wintering seasons within the proposed project area

Sea turtles - all species

The proposed action has the potential to adversely affect nesting females, eggs, hatchlings, and post-hatchling washbacks within the action area. The effects of the proposed action on sea turtles will be considered further in the remaining sections of these biological and conference opinions. For loggerhead turtles, specifically, the focus of these biological and conference opinions will consider the effects of the proposed action on nesting loggerheads from North Carolina and the Northern subpopulation, as well as the southeastern U.S. population as a whole.

Other Species

In addition to the four species and proposed critical habitat that are the subject of this formal consultation and conference, the FHWA has determined that, based on lack of habitat, the project will have no effect on the red-cockaded woodpecker (*Picoides borealis*) and red wolf (*Canis rufus*). We concur with these determinations. Also, the FHWA has determined that the project may affect, but is not likely to adversely affect the roseate tern (*Sterna dougallii*), West Indian manatee (*Trichechus manatus*) and seabeach amaranth (*Amaranthus pumilus*). Based on available information, the USFWS concurs with these determinations. The hawksbill sea turtle (*Eretmochelys imbricata*) and Kemp's ridley sea turtle (*Lepidochelys kempii*) do not normally nest in North Carolina, but occur in waters off the North Carolina coast. These two turtle species, along with the shortnose sturgeon (*Acipenser brevirostrum*), fall within the purview of the NMFS. The species discussed in this paragraph will not be considered further in this consultation.

III. ENVIRONMENTAL BASELINE

Under section 7(a)(2) of the ESA, when considering the "effects of the action" on federally listed species, the USFWS is required to take into consideration the environmental baseline. The environmental baseline includes past and ongoing natural factors and the past and present impacts of all federal, state, or private actions and other activities in the action area (50 CFR 402.02), including federal actions in the area that have already undergone section 7 consultation,

and the impacts of state or private actions which are contemporaneous with the consultation in process.

A. Status of the Species Within the Action Area

Piping Plover

Piping plover habitat within the action area occurs within an area affected by dynamic coastal processes and ongoing human uses. Suitable piping plover habitat appears to be present at and near Oregon Inlet, Green Island and along the ocean shoreline. Along the existing NC 12, artificial berms are constructed and maintained to protect NC 12 from rising high tide lines and erosion. The longshore transport of sediments continues to operate, but not the cross-island transport that maintains optimal piping plover habitat. This may result in the species currently concentrating near Oregon Inlet.

There is minimal piping plover breeding activity within the action area. Breeding activity has only been observed along both sides of Oregon Inlet. One breeding pair has been recorded at Bodie Island Spit on the north side of Oregon Inlet during five out of the last ten years (2001, 2002, 2004, 2006 and 2007)(Cameron 2008a, *in litt.*; NCWRC 2008b). During this same timeframe, one nest was observed in each of the years 2001, 2002, 2004 and 2007. In 2007, three chicks hatched, and one fledged, from a nest on Bodie Island Spit approximately 1700 feet northeast of the existing Bonner Bridge (NPS 2007a, NPS 2007b). One or two breeding pairs were observed on the south side of Oregon Inlet on PINWR during each of the years from 1998 to 2003 (Cameron 2008a, *in litt.*; NCWRC 2008b), with one nest being observed in 2001 and 2002 (Sue Cameron, NCWRC waterbird biologist, pers. comm. March 24, 2008). Vegetation succession on the south side of Oregon Inlet has reduced favorable nesting habitat there. In 2007, the action area accounted for only 1.6% of piping plover breeding activity within North Carolina (one out of 61 breeding pairs)(Cameron 2008b, *in. litt.*; NCWRC 2008c).

The number of piping plovers within the action area during the winter or migration is more difficult to assess. Regular surveys have not been conducted for non-breeding (including migrating and overwintering) plovers. However, non-breeding piping plovers have been observed within the action area, primarily at Bodie Island Spit (Cameron 2008, *in litt.*; NCWRC 2008a, NPS 2007a, NPS 2006b). Cohen et al. (in press) found that wintering plovers used ocean beach, sound beach and sound islands near Oregon Inlet. They estimated a minimum total wintering population of 11 birds in the vicinity of Oregon Inlet (including Green Island) during the winter of 2006/2007.

Proposed critical habitat for wintering piping plovers, Unit NC-1 Oregon Inlet, lies within the action area (USFWS 2008d). This unit contains a mix of intertidal beach and sand and/or mud flats (between annual low tide and annual high tide) with no or very sparse emergent vegetation, and adjacent areas of unvegetated or sparsely vegetated dune systems and sand and/or mud flats above annual high tide. Unit NC-1 is the northernmost critical habitat unit proposed within the wintering range of the piping plover. Consistent use by wintering plovers has been reported at Oregon Inlet dating from the mid-1960s. As many as 39 plovers have been reported from single day surveys during the fall migration (NCWRC 2008a). Cohen et al. (in press) reported

wintering birds using portions of the proposed Unit NC-1. Recent surveys have also recorded use of proposed Unit NC-1 by at least one banded piping plover from the endangered Great Lakes breeding population, with at least nine other birds recorded at other sites within the Dare County portion of the Outer Banks (Stucker and Cuthbert 2006). Until recently, limited banding has been done in the Great Plains population, so it is uncertain whether or to what extent birds from this population winter in this unit.

Loggerhead sea turtle

Loggerhead turtles usually nest from late April or early May through mid-September (Meylan et al. 1995). From 1996 to 2006, there were a total 126 loggerhead nests observed within the action area, averaging 11.5 nests per year (Godfrey 2008, *in litt.*).

Green sea turtle

Green turtles usually nest from late May or early June to early or mid-September (Woodson and Webster 1999). From 1996 to 2006, there were 5 or 6 green turtle nests observed within the action area, averaging 0.5 nests per year (Godfrey 2008, *in litt.*; USFWS 2008c, *in litt.*).

Leatherback sea turtle

Nesting by leatherback turtles is rare in North Carolina, with only 10 nests documented statewide in 2007 (SCDNR 2007). From 1996 to 2006, no leatherback nests were documented within the action area (Godfrey 2008, *in litt.*).

Summary of the status of sea turtles at within the action area

From 2000 to 2006, the extent of sea turtle nesting within the action area annually represented 0.9 to 2.3% of total sea turtle nesting in North Carolina (Godfrey 2008, *in litt.*; NPS 2007c). Although the USFWS recognizes sea turtles can occur and will nest within the action area, the total number of turtle nests potentially affected is relatively small when compared to the recovery and survival needs of each species.

B. Factors affecting species environment within the action area

A number of ongoing anthropogenic and natural factors may affect the species addressed in these biological and conference opinions. Many of these effects have not been evaluated with respect to biological impacts on the species. In addition, some are interrelated and the effects of one cannot be separated from others. Known or suspected factors affecting the species addressed in these biological and conference opinions are discussed below.

Manteo (Shallowbag) Bay Project

The Army Corps of Engineers (COE) completed formal consultation, pursuant to section 7 of the ESA, with the USFWS in December 1990 for maintenance dredging at Oregon Inlet that would place about 1.5 million cubic yards of dredged sediments per year on the ocean beaches at

PINWR. The COE subsequently reinitiated consultation four times, with the USFWS subsequently providing amendments to the original biological opinion on July 12, 1991; August 1, 2001; June 11, 2002; and May 22, 2008. The June 2002 amendment addressed the modification of the inlet dredging to include the removal of 1.3 to 1.8 million cubic yards of sediments from the inlet and the southern end of Bodie Island spit and disposal of the material on the beaches of PINWR. The biological opinion allowed incidental take of up to one sea turtle nest. This take could take the form of burial or crushing of a nest, or inhibition of nesting due to beach disturbance or scarp formation associated with the placement of dredge material on the beach.

Terminal Groin

Oregon Inlet is part of a migrating barrier island system. Oregon Inlet is migrating south-southwest and historically was eroding the north end of Hatteras Island. In order to protect the Bonner Bridge, the NCDOT completed the construction of a terminal groin on the north end of Hatteras Island in 1991. This structure armored the north shore of Hatteras Island and ended the migration of the north end of the island. As a result, the natural barrier island processes which create piping plover habitat have stopped at the south side of Oregon Inlet. Furthermore, armoring the shore has resulted in increased vegetation coverage and succession which reduces the quantity and quality of piping plover habitat.

Sand Berm Construction

The NCDOT regularly reconstructs the sand berms along portions of NC 12 in PINWR and CAHA. The project varies in scale and scope, but typically entails placing sand that has washed or blown from the seaward dune onto the road back into the footprint of the seaward dune, and is intended to maintain access along NC Highway 12. Typically, the federal nexus for these projects are the required special use permits issued by PINWR and CAHA. Before a special use permit can be issued, the appropriate office must first consult with the USFWS's Raleigh Field Office under the provisions of the ESA.

The sand berm construction occurs in areas potentially used by piping plovers for foraging. Anticipated impacts of sand berm construction on piping plovers include:

- harassment in the form of disturbing foraging, migrating or wintering birds;
- preclusion of cross-island transport processes that form and maintain optimal habitat; and,
- destruction of foraging habitat.

Sand berm construction also occurs in areas used by sea turtles for nesting. Anticipated impacts of sand berm construction on sea turtles include:

- destruction of sea turtle nests and deposited eggs that may have been missed by a nest survey and egg relocation program;
- reduced hatching success due to egg mortality during relocation and adverse conditions at the relocation site;

- harassment in the form of disturbing or interfering with female sea turtles attempting to nest within the construction area or adjacent beaches as a result of construction activities;
- disorientation of hatchling sea turtles on beaches adjacent to the construction area as they emerge from nests and crawl to the water because of project lighting; and
- limiting the width of the nesting beach.

Lighting

The extent that lighting affects piping plovers is unknown. However, there is evidence that American oystercatcher (*Haematopus palliatus*) chicks and adults are attracted to vehicle headlights and may move toward areas of ORV activity. During a 2005 study at Cape Lookout National Seashore, adult and chick oystercatchers were observed running or flying directly into the headlights of oncoming vehicles, and two two-day old oystercatcher chicks were run over by an all-terrain vehicle after being observed foraging with the adults near the high tide line at night (Simons et al. 2005). ORV driving is prohibited within most of the action area, being limited to the northernmost portion of the action area on the southern end of Bodie Island at Oregon Inlet, and approximately 1.1 miles of beach southward from the southern boundary of PINWR.

Although extensive monitoring of the effects of lighting on sea turtles has not been conducted within the action area, the southern end of the action may be affected by light originating from the village of Rodanthe.

Predation

Predation of piping plovers has not been directly observed within the action area, but predation and nest abandonment because of predators have been implicated as a cause of low reproductive success at CAHA (Cooper 1990, Coutu et al. 1990, Kuklinski et al. 1996). Mammalian and avian predators are relatively common within the action area. Red foxes (*Vulpes vulpes*) are relatively recent arrivals within the action area. Red foxes were first observed within CAHA on Bodie Island in 1996 and on Hatteras Island in 2000 (NPS 2001). Due to the presence of tracks, red foxes are suspected in disappearances of piping plovers and nest abandoning. Predation of sea turtle nests and hatchlings at CAHA has been documented. Red foxes and ghost crabs (*Ocypode* spp.) have been known to depredate sea turtle nests (NPS 2007c).

Stochastic (Random) Events

The impacts of tropical storms and associated coastal erosion on piping plovers within the action area have not been assessed. However, such events have the potential to destroy nests. Extremely cold temperatures may also adversely affect wintering birds.

High tides and storm surges from tropical weather systems can overwash, wash out, or inundate sea turtle nests. In the last several years, hurricanes and tropical storms have resulted in substantial impacts to the coastal environment along the action area. Erosion resulted in a reduction of beach profile in some areas and an accretion of sand in others. In the last ten years

(1998 to 2007), zero to nine sea turtle nests per year were lost within PINWR to storms and inundation (USFWS 2008c).

Habitat Management and Protection

With the exception of the southern terminus of the action area near Rodanthe, the coastline of the action area is under public ownership, either as CAHA or PINWR. Public ownership confers some conservation benefit to listed species, but land use decisions by the government agencies managing these lands ultimately determines the extent of conservation value these areas will have for threatened or endangered species.

In all cases, public ownership removes some threats that might otherwise be present if the properties were owned by private landowners and subsequently developed according to existing zoning regulations. In most cases, public ownership precludes the need for coastal armoring or beach nourishment, since these activities on public lands are rarely deemed appropriate (but see **Manteo Bay Project** section above). Thus, adverse effects to sea turtles and piping plovers associated with these activities are avoided or minimized on public lands. Public ownership also minimizes the likelihood that light pollution from homes and other development will become a significant problem since no commercial and residential development will occur on public lands. Therefore, along the shoreline of public parcels, disorientation of adult or hatchling sea turtles or piping plovers due to artificial lighting of homes or businesses will have been avoided or greatly reduced with public ownership.

Vehicle Use on the Beach

Oregon Inlet is one of the first beach access points for ORVs within CAHA when traveling from the developed coastal communities of Nags Head, Kill Devil Hills, Kitty Hawk, and Manteo. As such, the inlet spit is a popular area for ORV users to congregate. A recent visitor use study of the park reported that Oregon Inlet is the second most popular ORV use area in the park (Vogelsong 2003). As a result, sandy beach and mud and sand flat habitat being proposed as critical habitat in this unit may require special management considerations or protection. The Bodie Island Spit and an approximately 1.1 mile section of beach south of the southern boundary of PINWR are the only portions of the action area where vehicles are allowed on the beach.

Vehicles can significantly degrade piping plover habitat and disrupt normal behavior patterns of the birds. ORV users routinely violate bird closure areas (NPS 2006a, NPS 2007a). While there are no records of plover mortality at Oregon Inlet due to vehicles or tire ruts, the prospects of finding a dead, small, sand-colored bird or chick is unlikely. During the winter of 2005/2006, Cohen et al. (in press) found that when piping plovers used ocean beach habitat at Oregon Inlet, plovers were far more likely to use the PINWR side of Oregon Inlet (96% of the time; no ORV use) than the Bodie Island side (4% of the time). The lesser use of the Bodie Island side coincides with the ORV use there. They also found that piping plovers commonly roosted on the PINWR side, but only rarely roosted on the Bodie Island side, despite the fact that the Bodie Island side was closer to their foraging sites. They recommended controlled management experiments to determine if recreational disturbance drives roost site selection at Oregon Inlet, and if control of disturbance might lead to increased use of the northern beach as a roost area.

As a result of a recent lawsuit in federal court, a settlement was agreed upon that would increase protection for breeding plovers within CAHA. Terms of the consent decree will result in buffers being established during portions of the spring and summer around bird breeding and nesting areas, including creating a 1000 meter vehicle perimeter around piping plover chicks until they have fledged (NPS 2008b).

The use of ORVs on sea turtle nesting beaches can adversely affect the egg, hatchling, and nesting life stages of sea turtles. There are no specific records of vehicles colliding with nesting turtles or hatchlings within the action area, but the potential exists since ORV users have been reported to violate closed areas (NPS 2007c). Impacts from vehicles running over sea turtle nests have been reported at other locations within CAHA (NPS 2007c).

Vehicular ruts create obstacles for sea turtle hatchlings moving from the nest to the ocean. Possible mortality of hatchlings can occur due to being trapped in tire ruts. In addition, indirect effects may occur from weakened individuals dying at sea or made more vulnerable to predators. CAHA implements measures (including closures around known nests) to manage these effects. Another potential indirect effect of vehicular traffic is compaction of beach sediments under the weight of vehicles, thus creating suboptimal nesting habitat conditions.

Pedestrian Use of the Beach

Though no statistics exist to quantify the amount of pedestrian traffic on the beaches within the action area, evidence exist that people walking on the beach affects nesting and wintering piping plovers and nesting sea turtles and their nests, eggs, and hatchlings. Closure areas are established to protect plovers and sea turtles, but pedestrians sometimes violate these (NPS 2008a, NPS 2007a, NPS 2007c). Pedestrians have been documented harassing nesting sea turtles within CAHA (e.g. crowding around nesting turtle and taking flash photographs) and digging within turtle nests (NPS 2007c). Pedestrian use is allowed day and night within CAHA, but only during the day within PINWR.

Dog Use on the Beach

Dogs on a leash are allowed within both CAHA and PINWR, except in designated areas where no dogs are allowed. However, violations occur and enforcement is difficult because of the limited number of NPS and USFWS staff. Dogs running freely on beaches are potential predators of piping plover eggs and chicks, and can harass nesting, migrating or wintering adults. Dogs are also potential predators of sea turtle eggs, hatchlings, and even adult sea turtles. Unleashed dogs have been observed digging into nests. However, the extent of the effects from these actions to plovers and sea turtles within the action area is unknown.

IV. EFFECTS OF THE ACTION

Under section 7(a)(2) of the Act, "effects of the action" refers to the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are

interrelated or interdependent with that action. The federal agency is responsible for analyzing these effects. The effects of the proposed action are added to the environmental baseline to determine the future baseline, which serves as the basis for the determination in these biological and conference opinions. Should the effects of the federal action result in a situation that would jeopardize the continued existence of the species, we may propose reasonable and prudent alternatives that the federal agency can take to avoid a violation of section 7(a)(2). The discussion that follows is our evaluation of the anticipated direct and indirect effects of the proposed project. Indirect effects are those caused by the proposed action that occur later in time but are still reasonably certain to occur (50 CFR 402.02).

A. Factors to be considered

Piping plovers

Proximity of the action: The proposed action occurs within the nesting range of the Atlantic Coast piping plover breeding population. Since recovery units have been established in an approved recovery plan, these biological and conference opinions consider the effects of the proposed project on plovers in the Southern recovery unit, as well as the Atlantic Coast population and the entire species. The proposed action also occurs within the migrating and overwintering range of all three breeding populations of the piping plover. Additionally, the proposed action would occur within one proposed critical habitat unit for wintering plovers.

Distribution: The expected disturbance from the proposed action is likely to occur throughout the action area, but in a staggered manner over time.

Timing: The proposed action will occur throughout the year. Specifically, the proposed action will occur during the breeding, migrating and wintering seasons of the piping plover.

Nature of the effect: The project may affect breeding, nesting, migrating, roosting, or foraging activities of piping plovers. This may take the form of habitat loss, new habitat creation, preclusion of habitat utilization, harassment/disturbance resulting in behavior modification, and mortality in the form of egg, chick or adult death. Also considered are the potential effects on the primary constituent elements within one proposed critical habitat unit.

Duration/Disturbance frequency: The proposed project will be built in four phases, with Phase I beginning in 2009 and Phase IV beginning approximately 2029 or 2030. Each phase will involve 3 – 3.5 years of construction. The construction of each phase will be continuous from start to finish, operating year-round. Therefore, construction will be staggered over an approximately 25 year time span, with gaps of no construction between each phase. Each phase will only affect a portion of the action area at any one time.

The phasing of the construction of Phases II to IV is based on assumptions corresponding to forecast shoreline erosion trends and maintaining minimum 230-foot buffer distance between the existing NC 12 edge of pavement and the active shoreline. These assumptions are based on worst-case scenario modeling of shoreline erosion and the location and likelihood of future breaches on Hatteras Island. Since these are forecasts only, the exact timing and scope of each

phase could change based on the reality of future shoreline erosion. As such, the duration of the construction should be viewed as an approximation. Since piping plovers may be present throughout the year, plovers could be affected at any time during any of the phases or during subsequent maintenance of the facility.

Although construction activity will be a temporary affect, the new structures will permanently alter the habitat for piping plovers, although not necessarily all negatively in the long-term. Natural barrier island processes, which are currently precluded along much of the action area by the maintenance of NC 12, will be allowed to resume to an extent. Also, maintenance of the facility will be an ongoing activity on both a periodic and as-needed basis.

Disturbance intensity: Although the potential for disturbance to the piping plovers throughout the action area is high, the intensity of the disturbance is only expected to be high at and near Oregon Inlet. The rest of the action area currently has relatively little use by plovers. Therefore, Phase I has the greatest potential to affect plovers. The intensity of disturbance will likely be greatest for nesting piping plovers (April 1 through August 31) since they are tied to a point on the landscape with a nest, or when rearing young that have not yet fledged. However, relatively little nesting occurs within the action area. The intensity of disturbance may also be high for wintering plovers at Oregon Inlet. However, the small loss of proposed critical wintering habitat will likely have a discountable effect.

Disturbance severity: Although Phase I has the potential to affect nesting piping plovers, the severity of the affect, considering all the Atlantic Coast nesting, is relatively minor. Impacts to wintering plovers are of particular concern for the endangered Great Lakes breeding population. At least one individually identifiable Great Lakes piping plover has been observed at Oregon Inlet (Stucker and Cuthbert 2006).

Sea turtles – all species

Proximity of the action: The proposed action occurs within the northern nesting range of the loggerhead, green, and leatherback sea turtles. Specifically, the proposed action occurs within the range of the Northern subpopulation of the loggerhead turtle.

Distribution: The expected disturbance from the proposed action is likely to occur on all ocean facing beaches throughout the action area.

Timing: The proposed action will occur throughout the year. Any effects to sea turtles are expected to occur primarily during the sea turtle nesting and hatching seasons from May 1 through November 15. The greatest effects may occur at night from construction lighting and lights from vehicles traveling on the finished facility.

Nature of the effect: The project may affect nesting sea turtles, eggs, and hatchlings. This may take the form of habitat alteration, new habitat formation, preclusion of habitat utilization, harassment/disturbance resulting in behavior modification, and mortality in the form of egg, hatchling or adult death. Based on nesting records for the last ten years, we expect

approximately 96% of all effects to sea turtles will involve loggerhead sea turtles and 4% will involve green and leatherback sea turtles.

Duration/ Disturbance frequency: The duration/disturbance frequency to sea turtles is similar to that described above for piping plovers; except that the effects will primary occur during nesting and hatching seasons from May 1 through November 15.

Disturbance intensity: The potential for disturbance to the sea turtle populations throughout the action area is highest for possible effects of construction lighting at night and lights from vehicles traveling on the finished facility.

Disturbance severity: Since nearly all the sea turtle nesting that occurs within the action area is by loggerheads, the severity of the disturbance to green and leatherback turtles is expected to be minimal. However, the effects to loggerheads could lessen the contribution of those turtles to the recovery goal for the northern nesting subpopulation of loggerheads. However, this may be balanced by possible habitat creation resulting from allowing natural barrier island processes to occur within more of the action area.

B. Analysis for effects of the action

Beneficial effects:

Since NCDOT maintains an artificial berm along the seaward side of NC 12 through most of the project area, natural barrier island processes such as ocean overwash, island migration and inlet formation have been mostly precluded, thus severely limiting the formation of new habitat for piping plovers. Elevating most of NC 12 onto a bridge will allow for the maintenance of the artificial berm to be discontinued, thus allowing the natural barrier island processes to resume. Ocean overwash and possible new inlets would likely create new potential habitat for plovers. Eventually, westward migration of the island would result in some portion of the bridges to be in the ocean eastward of the beach.

Similarly, elevating NC 12 onto bridges may potentially improve sea turtle nesting habitat. Currently, most of the beach along the seaward side of NC 12 is narrow, steep and subject to high wave energy. The potential nesting area is constrained to a narrow width along much of the action area by the artificial berm along NC 12. Elevating most of NC 12 onto bridges would allow the natural barrier island processes to widen the beach area available for nesting; however, as portions of the beach migrate westward underneath the bridge, some of the beach may not be suitable nesting habitat for some period of time as it would be underneath the bridge and subject to shading effects (thus affecting hatching and sex ratios). Eventually, portions of the beach would migrate westward beyond the bridge and potentially provide suitable nesting habitat. Turtles would have to crawl or swim between bridge piles in order to utilize the newly widened beach. The effect that the bridge piles would have on emerging sea turtles is expected to be minimal. Bouchard et al. (1998) found that simulated piles did not totally preclude nesting activity of loggerhead and green sea turtles at Melbourne Beach, Florida, but did reduce nesting in an area with piles on the beach by 41%. However, the simulated piles used in the study were

spaced 17 feet apart, whereas the piles for the Phase II, III and IV bridges will be 100-120 feet apart. This wider distance would likely have a much lesser affect on nesting activity.

Piping plover

Direct effects:

The most quantifiable effect on piping plovers pertains to breeding. The only nesting activity recorded within the action area has occurred at Oregon Inlet. Although no breeding pairs have been observed at the north end of Hatteras Island near the Inlet since 2003 (Cameron 2008a, *in litt.*; NCWRC 2008b), and habitat quality for nesting has declined in recent years due to vegetation encroachment, habitat quality can improve quickly with severe storms, so the site still has the potential for nesting activity. At the Bodie Island Spit, a single nest in each of the years 2001, 2002, 2004 and 2007 has been observed >0.25 mile east of the existing Bonner Bridge (NPS 2007b). The new bridge will be constructed 125-500 feet farther west of the existing bridge, thus farther from the known nesting sites. However, demolition of the old bridge will require the presence of heavy equipment and noise ~0.25 mile from the known nesting area. Although it is unlikely that any nesting habitat would be physically disturbed, it is possible that the presence of construction equipment, construction activity and associated noise may preclude or disrupt breeding behaviors, including courtship, egg laying, incubation, and chick rearing on part or all of Bodie Island Spit or the northern end of Hatteras Island for some portion of the construction of Phase I and demolition of the existing Bonner Bridge. In addition, the northern end of Phase II may have similar effects to the potential nesting area on the north end of Hatteras Island. These effects will be temporary, covering a subset of each of the estimated 3-3.5 year construction timeframes for Phases I and II. However, it is uncertain that any breeding pairs would be precluded from nesting. Anecdotal evidence implies that some or all of the preferred nesting sites may be sufficiently distant from the work zones to avoid disturbance effects. Phases III and IV will not be located near any currently suitable plover nesting habitat.

Due to fill and pile placement in Phase I, there will be a direct loss of <0.1 acre of beach that is potential foraging and roosting habitat. It is not anticipated that the presence of the completed new bridge will preclude piping plovers from foraging since plovers currently forage at the existing Bonner Bridge. Phases II, III and IV will not result in the direct loss of any current foraging or roosting habitat.

Perhaps the most likely and most widespread, but the least quantifiable, direct effect is disturbance and/or flushing of foraging or roosting plovers during the construction of each of the phases. The presence of heavy equipment, construction activity and associated noise will be in close proximity to potential foraging and roosting habitat. Phase I and the northern end of Phase II have the greatest likelihood of disturbing foraging or roosting plovers and/or precluding foraging/roosting habitat from being used on portions of Bodie Island Spit and the north end of Hatteras Island. Also, Phase I comes within 0.3 mile of soundside ephemeral intertidal shoals or flats that are used by foraging plovers. The rest of Phase II and all of Phases III and IV have the potential to effect foraging or roosting plovers, however these phases are located adjacent to portions of the action area that currently have less foraging/roosting activity. This effect will be

temporary and staggered over time and location, lasting for some subset of the estimated 3-3.5 year construction timeframe for each phase.

The biological effects of disturbance to foraging or roosting plovers are difficult to quantify. In general, however, we know that plovers require food and shelter. Any actions that limit their ability to feed or shelter probably have adverse effects on individual birds because flushed birds expend energy to avoid disturbance (Stillman et al. 2007). The degree that piping plovers are adversely affected depends largely on how much time they are precluded from feeding or sheltering in relation to the amount of time they would feed or shelter if they were not flushed. To evaluate the biological effects of flushing, the identity of individual piping plovers would have to be known and the amount and extent of flushing would need to be documented consistently over time for each bird. Furthermore, these individual birds would need to be followed throughout the year to determine if their survival rates or nesting success were lower than other birds not subjected to flushing. Given there are other factors that affect the survival or reproductive success of piping plovers (predation, weather, food availability and quality, etc.) it would be difficult to isolate the effects of flushing. A large number of individual birds would have to be studied over a relatively long period in order to attempt to quantify the effects of flushing. We are aware of no such long term and statistically robust studies.

Effects to proposed critical habitat:

Proposed critical habitat Unit NC-1 currently supports the primary constituent elements essential for the conservation of the species and does support consistent use by wintering piping plovers. Although the new bridge in Phase I will cross through approximately 1700 feet of proposed critical habitat on Bodie Island, the direct loss to fill and pile placement is <0.1 acre. The existing Bonner Bridge crosses through approximately 3680 feet of proposed critical habitat on Bodie Island, but is not part of the proposed critical habitat. The demolition of the existing bridge and the construction of the new bridge will likely have temporary direct effects to primary constituent elements (e.g. haul roads, ruts, hydrological effects, etc.). After construction and demolition are completed, all temporary structures will be removed and the habitat restored to pre-disturbance conditions. Therefore, the effect will be short-term (i.e. considerably less than the estimated 3.5 years for completion of Phase I). A portion of Phase II on Hatteras Island will occur adjacent to proposed critical habitat, but not within it.

Interrelated and interdependent effects:

The effects of the action under consultation are analyzed together with the effects of other activities that are interrelated to, or interdependent with, that action. An interrelated activity is an activity that is part of the proposed action and depends on the proposed action for justification. An interdependent activity is an activity that has no independent utility apart from the action under consultation.

Periodic bridge maintenance or repair activities may require the presence of inspectors and equipment to operate in the vicinity of potential piping plover habitat, thus causing disturbance to foraging/roosting plovers or precluding the use of habitat. These effects are difficult to

quantify. Disturbance from human recreation is already present, and thus the effect of maintenance and repair work would be additive to an existing level of disturbance.

In addition, the maintenance or repair activities may have temporary effects to the primary constituent elements of the proposed critical habitat. However, these effects would likely be short in duration since all disturbed areas would be restored to pre-disturbance conditions once the maintenance or repair is completed.

Indirect effects:

Indirect effects are caused by or result from the proposed action, are later in time, and are reasonably certain to occur. If, by the elevation of much of NC 12 onto bridges and allowing natural barrier island processes to resume, new piping plover habitat is created in the future (see **Beneficial Effects** above), new conditions will exist for indirect effects. These indirect effects will be identical to the direct effects described above (i.e. effects on nesting, disturbance/flushing of foraging/roosting plovers, and precluding habitat use) during maintenance or repair activities; however, they will be to plovers using habitat that does not currently exist. If new piping plover habitat is created, portions of the beach will eventually move westward underneath the new bridges. The effect of having a bridge immediately overhead or adjacent to potential nesting habitat is unknown. Foraging under or adjacent to bridges is not expected to preclude foraging since plovers currently forage adjacent to the existing Bonner Bridge.

Depending on final design of each bridge, the new bridges could provide perches for predators (e.g. gulls, crows, etc.) that may prey on piping plover adults, chicks or eggs. However, these predators currently fly over piping plover habitat, so the extent of any additional effect would be difficult to determine.

Sea Turtles - All Species

Direct effects:

None of the project will be built within existing sea turtle nesting habitat; therefore, there will be no direct loss of turtle nesting habitat. However, all four phases will be built in close proximity to turtle nesting beaches. The greatest potential direct effects will likely be those caused by the use of construction lighting.

The USFWS recognizes that lights have the potential to disorient both hatchlings and nesting females. Artificial lighting can cause misorientation or disorientation (Philibosian 1976, Mann 1977, Witherington 1990). Misorientation can result in fatigue, dehydration, and increased likelihood of predation (Witherington et al. 1996). The correlation between level of light-caused disruption and survivorship has not, however, been identified. It has been demonstrated that there are relative degrees of sub-lethal and lethal effects (Salmon et al. 1995a; Witherington et al. 1996).

The effects of construction lighting will be temporary and staggered over space and time as each of the four phases is built. The effect will be year-round during the 3-3.5 year construction

timeframe for each phase, with periods of no effect between each phase. There will be no permanent lighting on bridge.

Other possible direct effects include disturbance of nesting females from noise or vibration from construction equipment. These effects would also be temporary and staggered over space and time.

Interrelated and interdependent effects:

Periodic bridge maintenance or repair activities may require the presence of inspectors and equipment to operate in the vicinity of potential sea turtle nesting habitat, thus causing disturbance to nesting females or emerging hatchlings, or precluding the use of nesting habitat. It is assumed that maintenance or repair activities would not occur at night, therefore minimizing the level of effects. When, in the future, portions of the beach migrate west of the bridge and sea turtle nesting beach is adjacent to the bridge, any vehicles or equipment driving on the beach for maintenance or repair activities could run over undetected turtle nests.

Indirect effects:

If, by the elevation of much of NC 12 onto bridges and allowing natural barrier island processes to resume, new sea turtle nesting habitat is created in the future, or if existing sea turtle nesting beach is widened and improved in quality (see **Beneficial Effects** above), new conditions will exist for indirect effects. Sea turtle nesting beach is currently limited in width by the artificial berm along the seaward side of NC 12. In Phases II, III and IV, the berm will be incrementally eliminated, and sea turtles may nest farther inland on the newly widened beach. This may result in sea turtles nesting near, under or beyond the new bridges. The presence of bridge piles and bridge superstructure overhead will alter light levels, beach morphology, and sand characteristics. It is important to note that the following indirect effect would occur to sea turtle nesting habitat that does not currently exist, but would be expected to exist sometime in the future.

From 2020 to 2060, it is estimated that up to 1.8 miles of NC 12 will be over dry beach at any one time, shading up to 9.5 acres of potential turtle nesting habitat. Shading would provide overall less desirable nesting conditions since beach sands shaded by the bridge would be expected to have a lower temperature. Temperature is negatively correlated with egg development time, so eggs under the bridge may display increased incubation time thus potentially exposing them to increased threats (e.g. predation, tidal inundation). Temperature also strongly determines gender of the hatchlings (Yntema and Mrosovsky 1982, Standora and Spotila 1985). Higher temperatures produce females, while lower temperatures produce males. Therefore beach shading by the bridge may alter the sex ratio of hatchlings. Since most nesting females emerge from the ocean at night, females may not be aware they are nesting underneath a bridge. These effects would be temporary since the beach would be expected to continue migrating westward.

As beach migration continues westward, portions of the nesting beach will eventually be located landward of the bridges. Turtles would have to crawl or swim between bridge piles in order to

utilize the newly widened beach. Over the life of the project, up to 3.3 miles of beach could have piles at any one time, thus potentially causing some level of deterrent to nesting. The effect that the bridge piles would have on emerging sea turtles is expected to be minimal. Bouchard et al. (1998) found that simulated piles did not totally preclude nesting activity of loggerhead and green sea turtles at Melbourne Beach, Florida, but did reduce nesting in an area with piles on the beach by 41%. However, the simulated piles used in the study were spaced 17 feet apart, whereas the piles for the Phase II, III and IV bridges will be 100-120 feet apart. This wider distance would likely have a much lesser affect on nesting activity. Again, this effect would be on nesting habitat that does not currently exist.

As portions of the beach migrate westward of the bridge, some bridge piles will be located within the nearshore waters. These bridge piles may attract and concentrate predatory fish. Predation on turtle hatchlings can be high in nearshore waters (Stancyk 1982, Wyneken and Salmon 1996). However, with bridge bents spaced 100-120 feet apart, increased predation due to the presence of bridge piles will likely be minimal.

Another indirect effect is that of vehicle lights traveling on the finished bridges. It is unknown whether vehicle lights moving parallel to the beach would discourage the emergence of nesting females. It is also unknown whether vehicle lights would misorient or disorient turtle hatchlings. Vehicle lights would not be a stationary source of light and would vary with differing levels of traffic. However, a higher traffic volume would likely occur during the summer tourist season, which overlaps with turtle nesting season. The height of the bridges and height of bridge barriers may mitigate some of the negative effects.

C. Species' response to proposed action

Piping plover

Numbers of individuals/populations in the action area affected: One breeding pair has been recorded at Bodie Island Spit on the north side of Oregon Inlet during five out of the last ten years (2001, 2002, 2004, 2006 and 2007)(Cameron 2008a, *in litt.*; NCWRC 2008b). During this same timeframe, one nest was observed in each of the years 2001, 2002, 2004 and 2007. In 2007, three chicks hatched, and one fledged, from a nest on Bodie Island Spit approximately 1700 feet northeast of the existing Bonner Bridge (NPS 2007a, NPS 2007b). One or two breeding pairs were observed on the south side of Oregon Inlet on PINWR during each of the years from 1998 to 2003 (Cameron 2008a, *in litt.*; NCWRC 2008b), with one nest being observed in 2001 and 2002 (Sue Cameron, NCWRC waterbird biologist, pers. comm. March 24, 2008). In 2007, the action area accounted for only 1.6% of piping plover breeding activity within North Carolina (one out of 61 breeding pairs)(Cameron 2008b, *in. litt.*; NCWRC 2008c). Overall, 0-3 breeding pairs have been observed in the action area for each of the last ten years.

The number of piping plovers within the action area during the winter or migration is more difficult to assess. Regular surveys have not been conducted for non-breeding (including migrating and overwintering) plovers. Cohen et al. (in press) estimated a minimum total wintering population of 11 birds in the vicinity of Oregon Inlet (including Green Island) during the winter of 2006/2007. As many as 39 piping plovers have been reported from single day

surveys during the fall migration at Bodie Island Spit, and as many as 41 plovers have been reported from single day Christmas Bird Counts at Oregon Inlet (NCWRC 2008a).

The total amount of proposed critical habitat to be permanently lost is <0.1 acre. An unknown acreage (though likely small amount) of proposed critical habitat will be temporarily affected during the construction phase.

Sensitivity to change: Piping plovers are sensitive to negative impacts during the breeding and non-breeding periods. Plovers may be deterred from nesting in given area where disturbance occurs. Sensitivity to change for non-breeding birds is difficult to assess. However, effects could be more detrimental for non-breeding plovers from the endangered Great Lakes population. Stucker and Cuthbert (2006) recorded at least one identifiable individual from the Great Lakes population wintering at Oregon Inlet, with at least nine other individuals of that population observed within CAHA outside the action area.

Resilience: Unless new inlets form within the action area, the breeding population of piping plovers is likely to remain low. However, elevating much of NC 12 onto bridges would allow natural barrier island processes to resume, potentially creating new inlets and plover habitat. Piping plover productivity has historically been low in all of North Carolina (NCWRC 2008c). However, improved protective measures and substantial decreases in disturbance to promote nesting opportunities and protect established nests and chicks could increase productivity.

The proposed critical wintering habitat within the action area is highly dynamic and resilient. Temporary disturbances will be unrecognizable in a short time.

Recovery rate: Piping plover habitat is inherently dynamic and carrying capacity fluctuates accordingly. The breeding population within the action has varied from zero to three pairs over the last ten years. At these low population levels, extirpation may occur for any number of reasons, including factors unrelated to the proposed action. While the specific recovery rate of piping plovers within the action area is unknown, the recovery rate is expected to be moderate if the birds are protected from all stressors. For example, several areas within the Atlantic Coast breeding population quadrupled their population size in as few as five years (USFWS 1996).

The specific effects of disturbance on non-breeding plovers are less well understood. However, reduced ability to rest and decreased food abundance could reduce survivorship of migrating and wintering birds. Demographic models for piping plovers, including two Atlantic Coast studies (Melvin and Gibbs 1994, Amirault et al. 2005), show that even small declines in adult and juvenile survival rates will cause substantial increases in extinction risk.

Other than the minimal amount of proposed critical habitat that would be permanently lost, the primary constituent elements within temporarily affected proposed critical habitat would recover very quickly after project construction ends.

Sea turtles – all species

Numbers of individuals/populations in the action area affected: From 1996 to 2006, there were a total 126 loggerhead nests observed within the action area, averaging 11.5 nests per year. From 1996 to 2006, there were 5 or 6 green turtle nests observed within the action area, averaging 0.5 nests per year. From 1996 to 2006, there were no leartherback turtle nests observed (Godfrey 2008, *in litt.*; USFWS 2008c, *in litt.*). From 2000 to 2006, the extent of sea turtle nesting within the action area annually represented 0.9 to 2.3% of total sea turtle nesting in North Carolina (Godfrey 2008, *in litt.*; NPS 2007c).

Sensitivity to change: Sea turtles are relatively sensitive to changes in the nesting environment, especially artificial light. There is high potential for nesting females and hatchlings to be misoriented or disoriented by construction lighting and possibly vehicle lights from the finished bridges. Sea turtle eggs are also sensitive to the nesting environment. The sex of an embryonic sea turtle is determined by the temperature of the nest environment. Shading effects on beach that has migrated underneath the bridges may change the nest environment by lowering sand temperature and changing the sex ratio.

Resilience: If fewer sea turtle hatchlings reach the ocean after hatching due to misorientation or disorientation from artificial light, fewer females will then return to nest at that location in the future. Also, loggerhead nests on North Carolina beaches (and in the Northern subpopulation) produce a greater proportion of males than do beaches in the southern part of the species' range. A reduction in the number of males contributed to the greater population may have adverse affects on future reproduction in the population. However, the extent of this effect is unknown.

Recovery rate: In general, the recovery rate of sea turtles is slow. Sea turtles reach sexual maturity at different ages depending on the species. Leatherback turtles can reach sexual maturity as early as six or seven years of age. However, loggerhead and green sea turtles do not reach sexual maturity until 20 to 50 years of age. If there is a reduction in the number of nests laid within the action area, and a subsequent reduction in the number of hatchlings produced, it may take decades before those hatchlings are contributing reproductively to the population.

V. CUMULATIVE EFFECTS

Cumulative effects include the effects of future state, local, or private actions that are reasonably certain to occur in the action area considered in these biological and conference opinions. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

Any maintenance activities on existing NC 12 that are conducted entirely within the NCDOT right-of-way do not have any federal nexus. These activities are most likely to occur after storm events in which sand is blown or washed over the road. Removal of the sand and reconstruction of the existing artificial berm would not be conducted within either piping plover or sea turtle habitat; however, the activities would be immediately adjacent to potential habitat. Disturbance from presence of heavy equipment, noise and vibration may flush piping plovers and preclude

foraging, roosting or nesting. This disturbance may also disturb nesting female sea turtles. Lights from construction equipment may misorient or disorient sea turtle hatchlings. These effects would be expected to be short in duration for each maintenance event, but have historically occurred several times a year. As portions of NC 12 are elevated onto bridges in Phases II, III and IV, these types of maintenance events would decrease.

The relocation of the former Oregon Inlet US Coast Guard Station may also have a similar short-term effect on piping plovers and sea turtles. However, this would be a one-time event.

VI. CONCLUSION

After reviewing the current status of the piping plover, loggerhead sea turtle, green sea turtle and leatherback sea turtle; the environmental baseline for the action area; and all effects of the proposed project, it is the USFWS's biological and conference opinion that the proposed replacement of the Bonner Bridge and subsequent phases of elevating portions of NC 12 onto bridges (TIP No. B-2500), as proposed, is not likely to jeopardize the continued existence of these species, and is not likely to destroy or adversely modify proposed critical wintering habitat for piping plover. No critical habitat has been designated for the loggerhead sea turtle; therefore, none will be affected. Critical habitat has been designated for the green sea turtle in Puerto Rico, and critical habitat has been designated for the leatherback sea turtle in the U.S. Virgin Islands; however, this action does not affect these areas and no destruction or adverse modification of that critical habitat is anticipated.

This non-jeopardy opinion is based, in part, on the following facts:

Piping plover

The Atlantic Coast nesting population of piping plover is a component of the entity listed as threatened which encompasses all breeding piping plovers except the Great Lakes breeding population. The Atlantic Coast population has increased from 790 pairs since listing to a preliminary estimation of 1,887 pairs in 2007 (USFWS 2008a). While the Great Plains populations experienced a decline of about 13 percent between 1991 and 2001, the overall status of the listed entity is likely to be increasing. The Southern recovery unit has gained 163 pairs since listing. As of 2007, the Southern recovery unit had 333 breeding pairs (USFWS 2008a). The abundance component of the recovery objective for the Atlantic Coast population and the Southern recovery unit is 2,000 and 400 breeding pairs, respectively (USFWS 1996).

The current number of breeding pairs using the action area (0-3 in the past ten years) is only a small part of the breeding population of the Southern recovery unit and the overall Atlantic Coast breeding population. In an unlikely worst case scenario, up to three breeding pairs could be precluded from nesting. However, it is uncertain that any breeding pairs would be precluded from nesting. Some or all of the preferred nesting sites may be sufficiently distant from the work zones to avoid disturbance effects.

The current number of piping plovers using the action area during migration and winter is significant, and the action area is an important migratory stopover site and over winter destination. Although the action area is relatively large, the adverse affects due to disturbance from construction will be staggered over space and time; therefore, only portions of the action area will see disturbance at any one time. The effects may contribute to a lessening of survivorship; however, this would be extremely difficult to determine.

Although uncertain, the project may have significant beneficial effects for piping plovers. As Phases II, III, and IV are constructed; the artificial berm along existing NC 12 will no longer be maintained, thus allowing natural barrier island processes such as island overwash, island migration and inlet formation to resume. At some point new habitat may be created for breeding, migrating, and wintering plovers via these natural processes.

Sea turtles

From 2000 to 2006, the extent of sea turtle nesting within the action area annually represented 0.9 to 2.3% of total sea turtle nesting in North Carolina (Godfrey 2008, *in litt.*; NPS 2007c). Over the past ten years, the action area averaged only 11.5 loggerhead nests and 0.5 green turtle nests per year. No leatherback turtles have been observed to nest within the action area (Godfrey 2008, *in litt.*). For loggerheads, the number represents only a miniscule contribution to the Northern subpopulation.

Other than the chance of a future maintenance or repair activity crushing an undetected nest, it is unlikely that any sea turtle nests will be directly lost. The most likely effect involves artificial lighting affecting nesting females and hatchlings during project construction. The total extent of this effect is unknown. However, artificial light from construction will be temporary and staggered throughout the action area over space and time. There will be no permanent light fixtures on the bridge. The permanent effect of vehicle lights traveling parallel to the beach is unknown. Other causes of disturbance due to construction will also be temporary.

Though uncertain, the project may have significant beneficial effects for nesting sea turtles. As Phases II, III, and IV are constructed; the artificial berm along existing NC 12 will no longer be maintained, thus allowing natural barrier island processes such as island overwash and island migration to resume. The existing beach along much of the action area is narrow, steep and subject to high energy wave action. With the elimination of the artificial berm along NC 12, the beach will widen and flatten out. Although the quality of the widened beach habitat may not be ideal for some period of time (i.e. while the bridge is overhead), and the permanent effects of vehicle lights overhead are unknown, there is the potential to eventually provide additional beach nesting opportunities where nests are less likely to be destroyed due to inundation and severe wave action.

Proposed species/critical habitat

The one proposed critical habitat unit for wintering piping plovers within the action area will continue to support primary constituent elements essential for the conservation of the species. The total permanent loss of proposed critical habitat will be <0.1 acre. Due to the dynamic

nature of the primary constituent elements, all temporary effects to the proposed unit will be indiscernible soon after construction is completed. For this reason it is our conference opinion that the proposed action is not likely to destroy or adversely modify proposed critical habitat.

INCIDENTAL TAKE STATEMENT

Section 9 of the ESA and federal regulations pursuant to Section 4(d) of the ESA prohibit the taking of endangered and threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. Harm is further defined by the USFWS to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns such as breeding, feeding or sheltering. Harass is defined by the USFWS as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of Section 7(b)(4) and Section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be prohibited taking under the ESA provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by the FHWA so that they may become binding conditions of any grant or permit issued to the NCDOT, as appropriate, for the exemption in section 7(o)(2) to apply. The FHWA has a continuing duty to regulate the activity covered by this Incidental Take Statement. If the FHWA (1) fails to assume and implement the terms and conditions or (2) fails to require the NCDOT to adhere to the terms and conditions of the Incidental Take Statement through enforceable terms that are added to the permit or grant document, the protective coverage of section 7(o)(2) may lapse. To monitor the impact of incidental take, the FHWA or the NCDOT must report the progress of the action and any impact on the species to the USFWS.

Amount or Extent of Take Anticipated

Piping plovers

- Breeding piping plovers: The USFWS expects incidental take of breeding plovers will be difficult to detect. The take would be the lost potential for nesting due to disturbance of breeding pairs at the nesting sites from nearby construction activity. It would be impossible to determine whether the lack of nesting or the absence of breeding pairs was due to the project or some other unrelated factor. It would only be possible to infer that the project directly caused the loss of a nest if an established nest was abandoned at the time construction began in the vicinity. Also, plover nests are cryptic and easily overlooked. However, this undetected level of take may occur near Oregon Inlet at historical nesting locations. Based on historical nesting data, the maximum level of incidental take is three breeding pairs per year precluded from nesting or caused to abandon nests during

construction for Phases I and II during each nesting season (i.e. April 1 to July 15) and the harassment of the associated breeding pairs.

- Migrating and wintering piping plovers: The USFWS expects incidental take of non-breeding plovers will be difficult to detect for the following reasons: sub-lethal effects are not easily determined; harassment which contributes to lessened survivorship may only be apparent on the breeding grounds the following year; and dead plovers may not be detectible. However, take of all migrating and wintering plovers throughout the extent of suitable habitat within the action area can be anticipated in all four phases of the project by the disturbance of feeding or roosting plovers from nearby construction activity.

Sea turtles - all species

The USFWS expects incidental take of all species of sea turtles will be difficult to detect for the following reasons:

- the turtles nest primarily at night and all nests are not found because (a) natural factors, such as rainfall, wind, and tides may obscure crawls and (b) human-caused factors, such as pedestrian and vehicular traffic, may obscure crawls;
- the total number of hatchlings per undiscovered nest is unknown;
- an unknown number of females may avoid the project beach and be forced to nest in a less than optimal area; and
- lights may misdirect an unknown number of hatchlings and cause death

However, take of all sea turtles throughout the extent of nesting habitat within the action area can be anticipated in all four phases of the project by harm or harassment due to the effects of artificial light and disturbance from construction and future maintenance and repair activities on nesting females and hatchlings. Also, as portions of the beach migrate westward, take of all undetected nests throughout the extent of the nesting habitat can be anticipated from future maintenance or repair activities that may crush undetected nests. Finally, as portions of the beach migrate westward, take of all nesting sea turtles throughout the extent of nesting habitat within the action area can be anticipated from reduced nesting by females deterred by bridge piles on the beach and by shading effects on sex ratios of eggs in nests constructed underneath the bridges.

Effect of the Take

In the accompanying biological and conference opinions, the USFWS determined that this level of anticipated take is not likely to result in jeopardy to the species, or destruction or adverse modification of designated or proposed critical habitat.

Reasonable and Prudent Measures

The USFWS believes the following reasonable and prudent measures are necessary and appropriate to minimize take of the piping plover, loggerhead sea turtle, green sea turtle, and

leatherback sea turtle. These nondiscretionary measures include, but are not limited to, the terms and conditions outlined in this biological and conference opinion.

Piping plover

1. Avoid disturbing nesting piping plovers.

2. To the extent possible, avoid disturbing foraging and roosting plovers.

3. To minimize the effect of harassment on foraging plovers, provide alternative foraging areas.

4. Avoid or minimize opportunities for avian predator perches.

Sea turtles – all species

1. Avoid disturbing nesting sea turtles, nests and hatchlings.

2. Educate construction contractors and pertinent NCDOT staff as to the adverse effects of artificial lighting on sea turtles.

3. Minimize the effects of construction lighting on nesting sea turtles and hatchlings.

4. Minimize the effects of vehicle headlights from the completed bridge.

5. Avoid permanent light fixtures.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the ESA, the NCDOT must comply with the following terms and conditions, which implement the reasonable and prudent measures described previously. These terms and conditions are nondiscretionary.

Piping plover

1. All construction equipment and personnel must avoid all bird closure areas within CAHA and PINWR.

   All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 – July 15).

   All future repair work on bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 – July 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for nesting plovers and avoided to the extent possible.

2. During the construction of Phases II, III and IV, keep all construction equipment and activity within the existing right-of-way.

   Do not moor any construction barges within 300 feet of the following islands: Green Island, Wells Island, Parnell Island, Island MN, Island C, the small unnamed island immediately east of Island C, Island D, and Island G (see figure 1).

3. All dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission. The point of contact is Sue Cameron at 910-325-3602. If the dredge material is used outside the current defined action area, the action area is assumed to be expanded to cover the beneficial placement of the material.

4. To the maximum extent practical, while ensuring the safety of the traveling public, limit or avoid the use of road signs or other potential predator perches adjacent to plover nesting or foraging areas. Where signs or other structures are necessary, determine if alternative designs would be less conducive for perching on by avian predators (gulls, crows, grackles, hawks, etc.). For example, minimize or avoid the use of large cantilever signs in favor of smaller and shorter designs.

Sea turtles – all species

1. All construction equipment and personnel must avoid all marked sea turtle nests.

   Construction material and equipment staging areas must not be located seaward of the artificial dune.

   All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the U.S. Coast Guard), must occur outside the nesting season (May 1 – November 15).

   All future repair work of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the U.S. Coast Guard) must occur outside the nesting season (May 1 – November 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for sea turtle nests and avoided to the extent possible.

2. Provide an opportunity for the USFWS or an USFWS designee to educate construction contractor managers, supervisors, foremen and other key personnel and resident NCDOT personnel with oversight duties (division engineer, resident engineer, division

environmental officer, etc.) as to adverse effects of artificial lighting on nesting sea turtles and hatchlings, and to the importance of minimizing those effects.

3. During turtle nesting season (May 1 – November 15), use the minimum number and the lowest wattage lights that are necessary for construction.

   During turtle nesting season, portable construction lighting must be of the low-pressure sodium-vapor type.

   During turtle nesting season, utilize directional shields on all portable construction lights, and avoid directly illuminating the turtle nesting beach at night.

   During turtle nesting season, all portable construction lights must be mounted as low to the ground as possible.

   During turtle nesting season, turn off all lights when not needed.

4. For Phases II, III and IV, on the ocean side, design the bridge structure in a manner which will shield the beach on the east side from direct light emanating from passenger vehicle headlights. For the small portion of Phase I over land on Hatteras Island, retrofit the bridge structure at the time that Phase II connects with Phase I. The specific design of the bridge will be developed in consultation with the USFWS prior to re-evaluation of the environmental document for Phase II.

5. Avoid retrofitting the bridges and approach roads with permanent light fixtures in the future (excluding navigation lights required by the U.S. Coast Guard).

Coordination of Incidental Take Statements with Other Laws, Regulations, and Policies

The USFWS will not refer the incidental take of any migratory bird for prosecution under the Migratory Bird Treaty Act of 1918, as amended (16 USC § 703-712), if such take is in compliance with the terms and conditions (including amount and/or number) specified herein.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of endangered and threatened species. The following conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or proposed critical habitat, to help implement recovery plans, or to develop information.

Piping plovers

The FHWA and/or NCDOT could contribute funding to the current CAHA predator removal program or any future PINWR predator removal program.

The pond located behind the terminal groin at the north end of Hatteras Island has historically provided foraging habitat for plovers whenever NCDOT has mined sand from it. The NCDOT could continue to utilize this pond as a source of sand for construction/maintenance purposes. The NCDOT could remove the sand such that the elevation and shape of the mined area is restored to a moist/wet sand habitat conducive to plover foraging. This should be coordinated with the PINWR. The point of contact is Dennis Stewart at 252-473-1131 ext. 231.

Sea turtles – all species

The FHWA and/or NCDOT could contribute funding to the Network for Endangered Sea Turtles (N.E.S.T.), a nonprofit organization dedicated to the preservation and protection of sea turtle habitat in the Outer Banks from the Virginia border to Oregon Inlet. N.E.S.T. monitors this area for nesting activity.

In order for the USFWS to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, we request notification of the implementation of any conservation recommendations.

REINITIATION/CLOSING STATEMENT

This concludes formal consultation on the action outlined in your March 5, 2008 request for formal consultation. As provided in 50 CFR section 402.16, reinitiation of formal consultation is required where discretionary federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

You may ask the USFWS to confirm the conference opinion as a biological opinion issued through formal consultation, if the critical habitat is designated. The request must be in writing. If the USFWS reviews the proposed action and finds that there have been no significant changes in the action as planned or information used during the conference, the USFWS will confirm the conference opinion as a biological opinion on the project and no further section 7 consultation will be necessary.

F.1. Publications and Technical Reports

A Joint Committee of the Department of Interior and the US Army Corps of Engineers. December 1991. *The US Army Corps of Engineers Plan to Stabilize Oregon Inlet*. Report to the Secretary of Interior and the Assistant Secretary of the Army.

Able, K. W., J. P. Manderson, and A. Studholme. 1998. "The Distribution of Shallow Water Juvenile Fishes in an Urban Estuary: The Effects of Man-Made Structures in the Lower Hudson River." *Estuaries,* 21: 731-44.

Able, K. W., J. P. Manderson, and A. Studholme. 1999. "Habitat Quality for Shallow Water Fishes in an Urban Estuary: The Effects of Man-Made Structures on Growth." *Marine Ecology Progress Series*, 187: 227-235.

Ableson, A., and M. Denny. 1997. "Settlement of Marine Organisms in Flow." *Annual Review of Ecology and Systematics*, 28: 317-339.

Adams, S. W. 1976. "The Ecology of Eelgrass Zostera Marina (L.), Fish Communities I. Structural Analysis." *Journal of Experimental Marine Biology and Ecology*, 22: 269-291.

Alexander, C., and M. Robinson. 2006. *Quantifying the Ecological Significance of Marsh Shading: Impact of Private Recreational Docks in Coastal Georgia*. Coastal Resources Division, Georgia Department of Natural Resources, Brunswick, Georgia.

Allison, J. L. 1990. "Air Cushion Vehicles and Surface Effect Ships for Great Lakes and Great Rivers Transportation." *Marine Technology,* 27: 337-355.

Ambrose, R. F., and T. W. Anderson. 1990. "Influence of an Artificial Reef on the Surrounding Infaunal Community." *Marine Biology,* 107: 41-52

American Association of State Highway and Transportation Officials. 2002. *Standard Specifications for Highway Bridges*. American Association of State Highway and Transportation Officials, Washington, DC.

American Fisheries Society. 1980. *A List of Common and Scientific Names of Fishes from the United States and Canada*. Fourth edition. American Fisheries Society, Washington, DC.

American Ornithologists Union. 1983. *Checklist of North American Birds*. Sixth edition. Allen Press, Inc. Lawrence, Kansas.

Anchor Environmental C. A., L. P. 2003. *Literature Review of Effects of Resuspended Sediments Due to Dredging Operations*. Prepared for Los Angeles Contaminated Sediments Task Force.

Angley, W. 1985. *An Historic Overview of Oregon Inlet.* Report on file at the Research Branch, North Carolina Division of Archives and History, Raleigh, North Carolina.

Architectural Conservation Associates. 1990. *Historical Structures Survey and Evaluation Report, Bonner Bridge, NC.* Prepared for the NC Department of Transportation, Raleigh, North Carolina.

Banks, R. C., R. W. McDiarmid, and R. L. Gardner. 1987. *Checklist of Vertebrates of the United States, the US Territories, and Canada*. US Fish and Wildlife Service Resource Publication No. 166.

Bard, A.M., H.T. Smith, T.V. Harber, G.W. Stewart, J.S. Weske, M.M. Browne, and S.D. Emslie. 2001. *International Conference on Ecology and Transportation*. Keystone, Colorado.

Baron, R. M., L. K. B. Jordan, and R. E. Spieler. 2004. "Characterization of the Marine Fish Assemblage Associated with the Nearshore Hardbottom of Broward County, Florida." *USA Estuarine, Coastal and Shelf Science,* 60: 431-443.

Barwick, M., and W. Maher. 2003. "Biotransference and Biomagnification of Selenium, Copper, Cadmium, Zinc, Arsenic, and Lead in a Temperate Seagrass Ecosystem from Lake Macquarie Estuary, NSW, Australia." *Marine Environmental Research,* 56: 471-502.

Basha, S., S. H. Desai, N. Anand, B. Jha, K. H. Mody, R. B. Thorat, P. M. Gaur, S. K. Mukhopadhyay, and R. H. Trivedi. 2007. "Heavy Metal Content of Suspended Particulate Matter at World's Largest Ship-Breaking Yard, Alang-Sosiya, India." *Water, Air, and Soil Pollution,* 178: 373-384.

Bayram, A., and M. Larson. 2000. "Analysis of Scour Around a Group of Vertical Piles in the Field." *Journal of Waterway, Port, Coastal, and Ocean Engineering*, 126: 215-220.

Bayram, A., and M. Larson. 1999. *Analysis of Scour Due to Breaking and Non-Breaking Waves Around a Group of Vertical Piles in the Field.* Proceedings of Coastal Structures 99, Santander, Spain, 7 – 9, June, 1999, vol. 2. Balkema, Rotterdam, Netherlands, pp. 763-771.

Bertolotti, Lesley, and Michael Salmon. 2005. "Do Embedded Roadway Lights Protect Sea Turtles?" *Environmental Management,* 36: 702-710.

Bilodeau, A. L., and R.P. Bourgeois. 2004. "Impact of Beach Restoration on the Deep-Burrowing Ghost Shrimp, *Callichirus islagrande*." *Journal of Coastal Research,* 20: 931-936.

Bindoff, Nathaniel L., Richard Alley, Terje Berntsen, Zhenlin Chen, Amnat Chidthaisong, Pierre Friedlingstein, Jonathan, Gregory, Gabriele Hegerl, Martin Heimann, Bruce Hewitson, Brian Hoskins, Fortunat Joos, Jean Jouzel, Vladimir Kattsov, Ulrike Lohmann, Martin Manning, Taroh Matsuno, Mario Molina, Neville Nicholls, Jonathan Overpeck, Dahe Qin, Graciela Raga, Venkatachalam Ramaswamy, Jiawen Ren, Matilde Rusticucci, Susan Solomon, Richard Somerville, Thomas F. Stocker, Peter Stott, Ronald J. Stouffer, Penny Whetton, Richard A. Wood, and David Wratt. 2007. *Climate Change 2007: The*

Physical Science Basis. Contribution of Working Group I to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change. Geneva, Switzerland. 21 pp.

Birkemeier, William A., and K. Todd Holland. 2001. "The U.S. Army Corps of Engineers' Field Research Facility: More Than Two Decades of Coastal Research." *Shore and Beach,* 69: 3-12

Black, Richard. 2003. *Leatherbacks' Extinct in 30 years*. BBC News World Edition. February 17.

Boone, J. 1988. *Small Mammal Response to Fire on Bodie and Hatteras Islands, Cape Hatteras National Seashore, North Carolina*. CPSU Technical Report No. 48, National Park Service. Athens, Georgia.

Boone, J., E. Furbish, and K. Turner. 1987. *Control of Phragmites Communis: Results of Burning, Cutting, and Covering with Plastic in a North Carolina Salt Marsh*. National Park Service, Cooperative Park Studies Unit, Institute of Ecology, University of Georgia, Athens, Georgia.

Booz, Allen and Hamilton. 1986. *Dare County Service Requirement and Development Options Cost Report.*

Booz, Allen and Hamilton. 1987 Update. *Dare County Carrying Capacity/Development Study*.

Bouchard, S., K. Moran, M. Tiwari, D. Wood, A. Bolten, P. Elizar, and K. Bjorndal. 1998. "Effects of Exposed Pilings On Sea Turtle Nesting Activities at Melbourne Beach, Florida." *Journal of Coastal Research*, 14: 1343–1347.

Bowman, M. and R. Dolan. 1982. "The Influence of a Research Pier on Beach Morphology and the Distribution of *Emerita Talpoida*." *Coastal Engineering,* 6: 179-194.

Boss, Stephen K. and Charles W. Hoffman. 2000. *Sand Resources of the North Carolina Outer Banks, 4th Interim Report: Assessment of Pea Island Study Area*. Prepared for the Outer Banks Task Force and the NC Department of Transportation.

Brody, A.J., and M.R. Pelton. 1989. "Effects of Roads on Black Bear Movements in Western North Carolina." *Wildlife Society Bulletin*, 17: 5-10.

Brooks, B., and M. Wilde-Ramsing. 1988. *Bibliography of North Carolina Underwater Archaeology*. North Carolina Division of Archives and Natural History. Raleigh, North Carolina.

Broome, S. W. 1990. "Creation and Restoration of Tidal Wetlands of the Southeastern United States," *Wetland Creation and Restoration: The Status of the Science*. Edited by J. A. Kisler and M. E. Kentula. Island Press, Washington, DC. pp. 37-72.

Brown, C. A. 1959. *Vegetation of the Outer Banks of North Carolina*. Louisiana State University Press. Baton Rouge, Louisiana.

Bruderer, B., D. Peter, and T. Steuri. 1999. "Behaviour of Migrating Birds Exposed to X-Band Radar and Bright Light Beam." *Journal of Experimental Biology*, 202: 1015-1022.

Burdick, D.M., and F.T. Short. 1999. "The Effects of Boat Docks on Eelgrass Beds in Coastal Waters off Massachusetts." *Environmental Management,* 23: 231-240.

Burger, J. 1991. "Foraging Behavior and the Effect of Human Disturbance on the Piping Plover (*Charadrius melodus*)." *Journal of Coastal Research,* 7: 39-52.

Burke, C. J. 1962. *The North Carolina Outer Banks: a Floristic Interpretation*. J. Elisha Mitchell Science Society. 78:21-28.

Byrnes, R. M., R. M. Hammer, T. D. Thibaut, and D. B. Snyder. 2004. "Physical and Biological Effects of Sand Mining Offshore Alabama, U.S.A." *Journal of Coastal Research,* 20(1): 6-24.

Carthy, R.R., A.M. Foley, and Y. Matsuzawa. 2003. "The Incubation Environment of Nests of the Loggerhead Turtle: Effects on Hatching Success and the Characteristics of Hatchlings." *In* Bolten, A.B. and B.E. Witherington (editors). *The Biology and Conservation of the Loggerhead Sea Turtle*. Smithsonian Institution Press, Washington D.C.

Catlin Engineers and Scientists. December 2003. *Preliminary Site Assessment for Parcel 2, 4, and 7 Joseph M. Midgett, Sr. Property, NC 12 Replacement of the Herbert C. Bonner Bridge (Br. #11) Over Oregon Inlet, Dare County, North Carolina.* Prepared for the NC Department of Transportation, Geotechnical Unit. Raleigh, North Carolina.

Clynick, B. G., M. G. Chapman, and A. J. Underwood. 2007. "Effects of Epibiota on Assemblages of Fish Associated with Urban Structures." *Marine Ecology Progress Series,* 332: 201–210.

Coffin, Alisa W. 2007. "From Roadkill to Road Ecology: A Review of the Ecological Effects of Roads." *Journal of Transport Geography*, 15: 396-406.

Collier, R. S., and M. C. Odom. 1989. *Obstructions to Anadromous Fish Migration*. Project No. 88-12, Albemarle-Pamlico Estuarine Study. NC Department of Natural Resources and Community Development and the Environmental Protection Agency National Estuary Program.

Conant, R., and J. T. Collins. 1991. *A Field Guide to Reptiles and Amphibians of Eastern and Central North America,* 3rd Edition. Houghton Mifflin Company, New York, New York.

Cooper, A. W. 1963. *Salt Marsh Studies on North Carolina Outer Banks, Volume 1: Vegetation Types in the Bodie Island Marsh*. Preliminary manuscript, Cape Hatteras National Seashore technical resources files.

Courtenay, W. R., Jr. B. C. Hartig, and G. R. Loisel. 1980. *Ecological Evaluation of Beach Nourishment Project at Hallandale (Broward County), Florida: Evaluation of Fish Populations Adjacent to Borrow Areas of Beach Nourishment Project. Hallandale (Broward County), Florida, Vol. I.* Miscellaneous Report 80-1(I). Fort Belvoir, Virginia: Coastal Engineering Research Center, US Army Corps of Engineers.

Cowardin, L. M., V. Carter, F. C. Golet, and E. T. LaRoe. 1979. *Classification of Wetlands and Deepwater Habitats of the United States*. US Fish and Wildlife Service Biological Service Program. Washington, DC. FWS/OBS-79/31.

Culver, S. J., Ames, D. V. Corbett, D. R. Mallinson, D. J. Riggs, S. R. Smith, C. G. and D. J. Vance. *In Review*. "Foraminiferal and Sedimentary Record of Late Holocene Barrier Island Evolution, Pear Island, North Carolina: The Role of Storm Overwash, Inlet Processes, and Anthropogenic Modification." *Journal of Coastal Research*, 22: 826-846.

CZR, Incorporated. 1977. *Environmental Impact Assessment of the Hatteras Island Inlet Ferry Operation and Required Maintenance Dredging*.

CZR, Incorporated. February 1992. *Natural Systems Technical Memorandum to the Environmental Impact Statement for Replacement of Herbert C. Bonner Bridge*. Prepared for the NC Department of Transportation, Raleigh, North Carolina.

CZR, Incorporated. January 1993. *A Survey of Nesting and Foraging Habitat Potentially Used by Piping Plovers Within the Area of the Preferred Herbert C. Bonner Bridge Alignment*. Prepared for the NC Department of Transportation, Raleigh, North Carolina.

CZR, Incorporated. 2003. *Waterbird and Shorebird Use of Beaches in Brunswick County, North Carolina*. Prepared for the U.S. Army Corps of Engineers, Wilmington District, Wilmington, North Carolina. Contract No DACW54-97-D-0028, Delivery Order 30.

CZR, Incorporated. 2005. *Natural Resources Technical Memorandum*. Prepared for the NC Department of Transportation. Raleigh, North Carolina.

CZR, Incorporated. 2008. *Essential Fish Habitat Assessment*. Prepared for PB Americas, Inc. and the North Carolina Department of Transportation.

Daiber, F. C. 1986. *Conservation of Tidal Marshes*. Van Nostrand Reinhold Co., New York.

Dames and Moore. 1979. *Report on a Remote Sensing Survey of Oregon Inlet, North Carolina*. Report for the US Army Corps of Engineers, Wilmington District, Wilmington, North Carolina.

Dare County. January 2001. *Dare County Emergency Operation Plan.*

Dare County. 2001. *Dare County Land Use Plan Update Issue Questionnaire Report of Findings.* Dare County, North Carolina.

Dare County. March 2003. *Dare County Land Use Plan, 2003 Update.* Dare County, North Carolina.

NC 12
Bonner Bridge Replacement Project

FINAL ENVIRONMENTAL IMPACT STATEMENT

Citizens' Summary and User Guide

U.S. Department of Transportation
Federal Highway Administration

North Carolina Department of Transportation

Dear Citizen:

Thank you for your interest in the Final Environmental Impact Statement (FEIS) for the Bonner Bridge Replacement Project. The project consists of replacing Bonner Bridge and providing for the long-term retention of NC 12 between Rodanthe and Oregon Inlet.

The Bonner Bridge is near the end of its service life and needs to be replaced. Its role in the regional transportation network has only increased over the last 40 years as the area's desirability for residential development and as a tourist attraction has increased. The primary purpose of the proposed project is to provide a new means of access from Bodie Island to Hatteras Island for residents, businesses, services, and tourists prior to the end of Bonner Bridge's service life.

The purpose of this ***Citizens' Summary and User Guide*** *is to answer both some commonly asked questions about the project as well as general questions about Environmental Impact Statements. This guide also provides an easy-to-follow summary of the major issues discussed in the NC 12 Replacement of Herbert C. Bonner Bridge FEIS. For in-depth discussion of these issues, please refer to the NC 12 Replacement of Herbert C. Bonner Bridge FEIS. The locations where you can view the FEIS are listed on page 14.*

The NCDOT welcomes and values your input and involvement in this project. Stay informed about the project by adding your name to the project mailing list and/or visiting the project web site at http://www.ncdot.org/projects/bonnerbridge repairs/. If you have questions or comments about the project or would like to be added to the project mailing list, please write, e-mail, or call:

PROJECT LOCATION

Project Description

What is the Bonner Bridge Replacement Project?

The Herbert C. Bonner Bridge (Bonner Bridge), opened in 1963, crosses Oregon Inlet and connects Bodie Island with Hatteras Island (see map above). Bonner Bridge is a part of NC 12 and provides the only highway connection between Hatteras Island and the North Carolina mainland. The Bonner Bridge Replacement Project (the Project) consists of replacing Bonner Bridge and providing for the long-term retention of NC 12 between Rodanthe and Oregon Inlet. The Preferred Alternative consists of a new bridge over Oregon Inlet (west of Bonner Bridge), and the construction of additional bridges within the NC 12 easement from Oregon Inlet to Rodanthe as needed to retain NC 12 in light of both ongoing shoreline erosion and the potential for island breaches in that area.

Why is Bonner Bridge being rehabilitated now?

The latest Bonner Bridge Assessment Report regarding the condition of the bridge was completed in December 2006. The purpose of the report was to identify repairs that could extend the life of the bridge 10 additional years until a replacement bridge could be built. An additional assessment of the condition of the bridge is currently underway.

NCDOT is in the process of making repairs identified in the report. Crews completed repairs to the bridge's subcaps and pile jackets in March 2008. A subcap is a piece of concrete that is placed on top of an existing cap on a piling to help support a bridge's load. A pile jacket is a steel and concrete structure that wraps around a piling to reinforce it.

Repairs to the bridge's concrete started in March 2008 and remain under way. Crews are chipping out the deteriorated concrete using jackhammers and replacing it with shotcrete. Shotcrete is concrete applied at high pressure, which adheres quickly and easily to the existing structure. The work is scheduled to continue through November 2010.

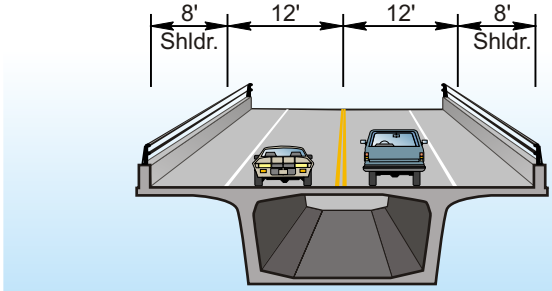
Work is scheduled within the next 12 months to rehabilitate the bridge's fender system. Comprised of wood and steel, the fender system surrounds the pilings and works like a buffer between the concrete bridge and oncoming vessels, protecting the bridge in case of watercraft impact. The project is expected to take about six months to complete.

Why does the Bonner Bridge need to be replaced?

Since its opening in 1963, Bonner Bridge has required continual maintenance. Projects continue to this day to address the following problems:

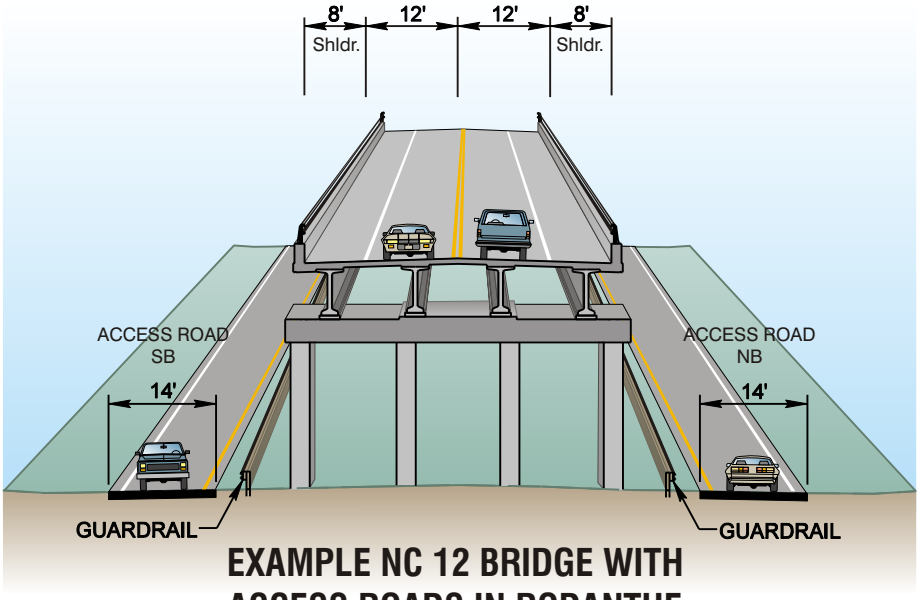
- Concrete fragments breaking off of the supporting structures (spalling);
- Corroded steel reinforcing rods exposed by spalling; and
- Wave action that undermines the piles' ability to support the superstructure.

Despite these maintenance efforts, the Bonner Bridge is near the end of its service life and needs to be replaced. Its role in the regional transportation network has only increased over the last 40 years, as the area's desirability for residential development and as a tourist attraction has increased. The purposes of the proposed project are to:



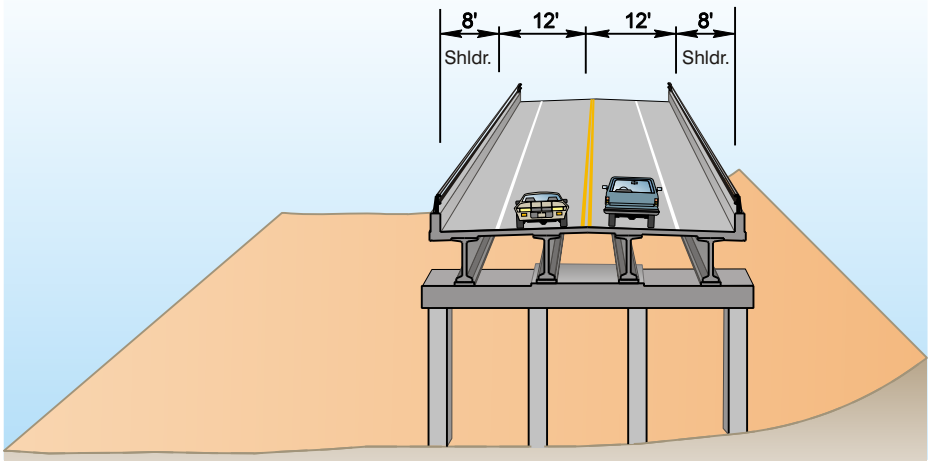
- Provide a new means of access from Bodie Island to Hatteras Island for its residents, businesses, services, and tourists prior to the end of Bonner Bridge's service life. Demand for convenient daily and emergency access across Oregon Inlet is expected to continue;
- Replace the bridge with a design that serves navigation needs, while also allowing natural channel movement and reducing future dredging needs; and
- Provide a replacement crossing that will not be endangered by shoreline movement through year 2050.

Why is the relocation of NC 12 to Rodanthe also a part of the project?



Bonner Bridge is a part of NC 12, the only road serving all of Hatteras Island. NC 12 is subjected to shoreline erosion and overwash, and requires regular post-storm closure and maintenance. There are three areas of high erosion along NC 12 between Oregon Inlet and Rodanthe, within the Pea Island National Wildlife Refuge (Refuge). These erosion "hot spots" are shown on the map on page 3. The operations of the Refuge are affected not only by NC 12 post-storm maintenance activities, but also by potential long-term solutions to ongoing shoreline erosion.

Thus, in order to help ensure NC 12 reliability over the life of the new bridge and to allow for the fullest range of possible alternatives to be considered, it was decided to examine the Bonner Bridge replacement and the long-term retention of NC 12 within a single project. If the project only included alternatives that terminate at the north end of Hatteras Island, other combined solutions, such as a long bridge that bypasses the Refuge, could not be considered.



EXAMPLE BRIDGE ACROSS OREGON INLET

EXAMPLE NC 12 BRIDGE WITH ACCESS ROADS IN RODANTHE

EXAMPLE NC 12 BRIDGE IN REFUGE

What is the Preferred Alternative and when will it be built?

The Preferred Alternative is the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (see map to the right). It was identified in August 2007 as the Least Environmentally Damaging Practicable Alternative (LEDPA) by partnering and cooperating environmental resource and regulatory agencies. The Preferred Alternative consists of a new bridge over Oregon Inlet (west of Bonner Bridge), and the construction of additional bridges within the NC 12 easement from Oregon Inlet to Rodanthe as needed. An example of the possible appearance of a new Oregon Inlet bridge is shown on page 4. Examples of the possible appearance of bridges in Rodanthe and through the Refuge are shown in the figures to the left. The final appearance of these bridges will be determined in final design.

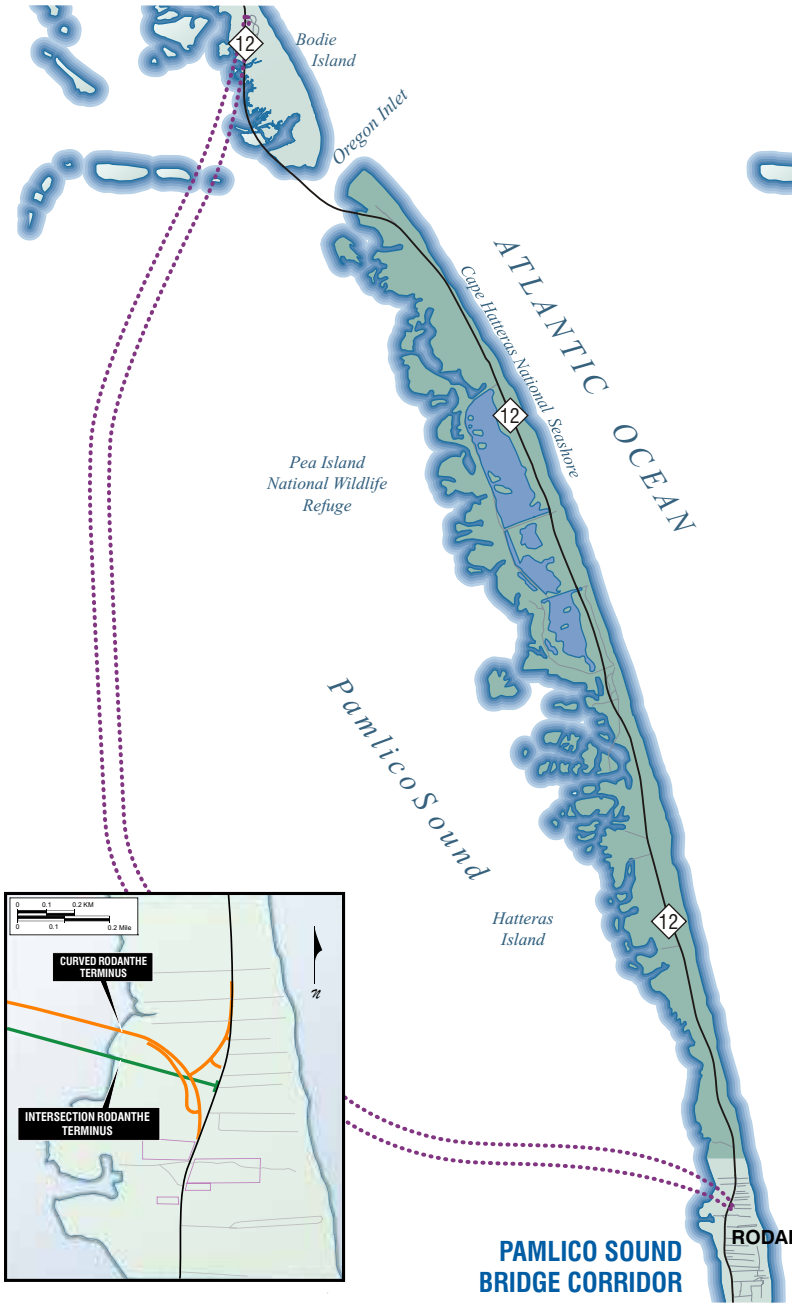
The project would be built in four phases as shown on the map to the right. The Oregon Inlet bridge replacement is Phase I. The additional phases are described below; however, NCDOT recognizes that these phases could be adjusted based on funding availability and changing coastal conditions within the project area:

- Phase II (blue on map) would bridge three locations where NC 12 is most threatened by shoreline erosion at the north end of Hatteras Island and in the Rodanthe area, including four potential storm-related island breach locations;
- Phase III (pink on map) would bridge the next area expected to be threatened by shoreline erosion (south of the freshwater ponds in the Refuge), including a fifth potential storm-related island breach location; and
- Phase IV (yellow on map) would bridge the final two areas where NC 12 is predicted to be threatened by shoreline erosion in the area of the Refuge's freshwater ponds.

One section of NC 12 in the Refuge would not be bridged because it is not expected to be threatened by shoreline erosion before 2060.

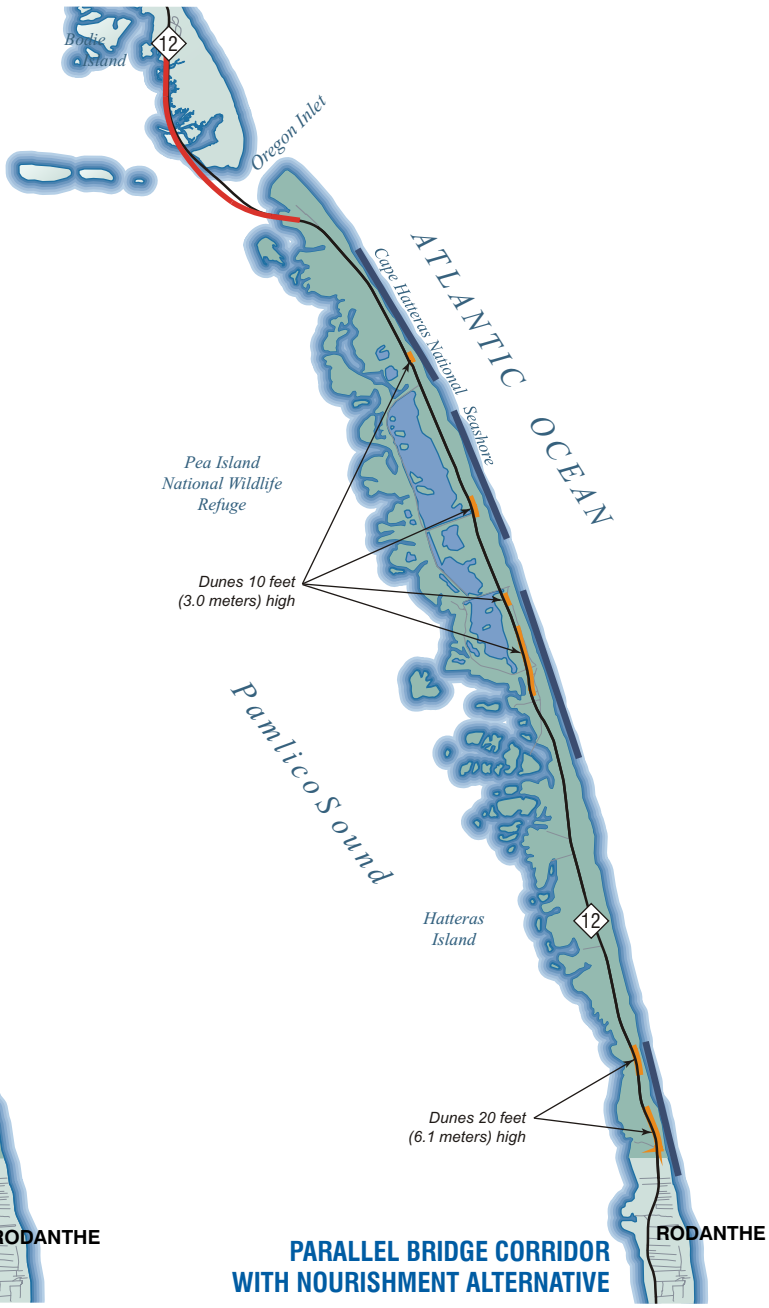
NCDOT will continue to monitor the shoreline within the Refuge and Rodanthe to determine the bridge length and construction schedule for Phases II - IV.

The "Design-Build" contract (see page 12 for an explanation of Design-Build) for Phase I, the replacement of Bonner Bridge, will be awarded in 2009. Phase I is expected to be completed in 2014. The construction duration for Phases II through IV is estimated to be approximately three years. The project timeline, as of August 2008, is shown on page 12.



How much will the Preferred Alternative cost, and how will it be financed?

The total projected cost of the Preferred Alternative ranges from a low of $1.2 billion to a high of $1.5 billion. This cost includes the new bridge over Oregon Inlet, demolition of the existing Bonner Bridge, all costs associated with construction of NC 12 roads and bridges (Phases II to IV), removal of the existing NC 12 pavement, additional right-of-way purchased on Bodie Island and in Rodanthe, wetland mitigation, and all operation and maintenance costs through 2060.

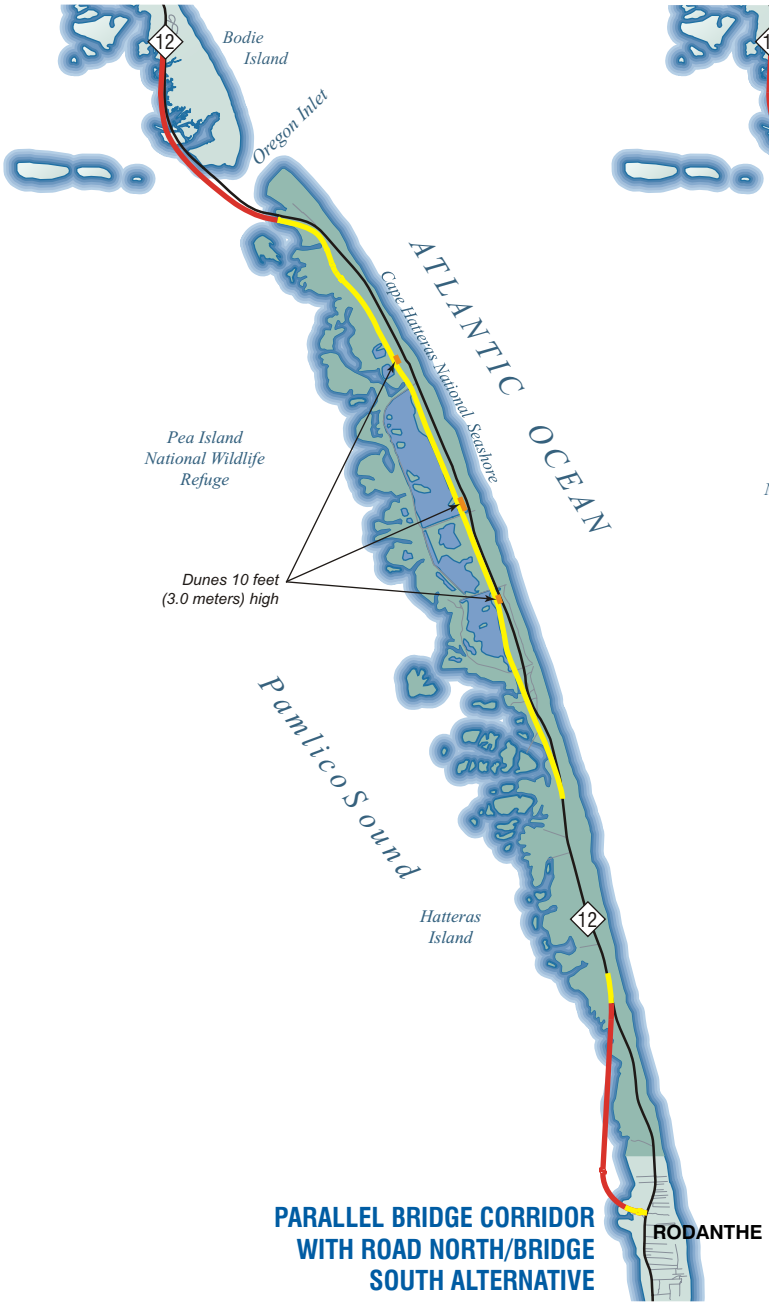


NCDOT will use transportation funds allocated in the State Transportation Improvement Program (TIP) for construction of the proposed project. By constructing the project in phases, construction costs can be spread-out over multiple TIP funding cycles; this way, the necessary funds can be planned for and spent as they become available.

PARALLEL BRIDGE CORRIDOR WITH PHASED APPROACH ALTERNATIVES

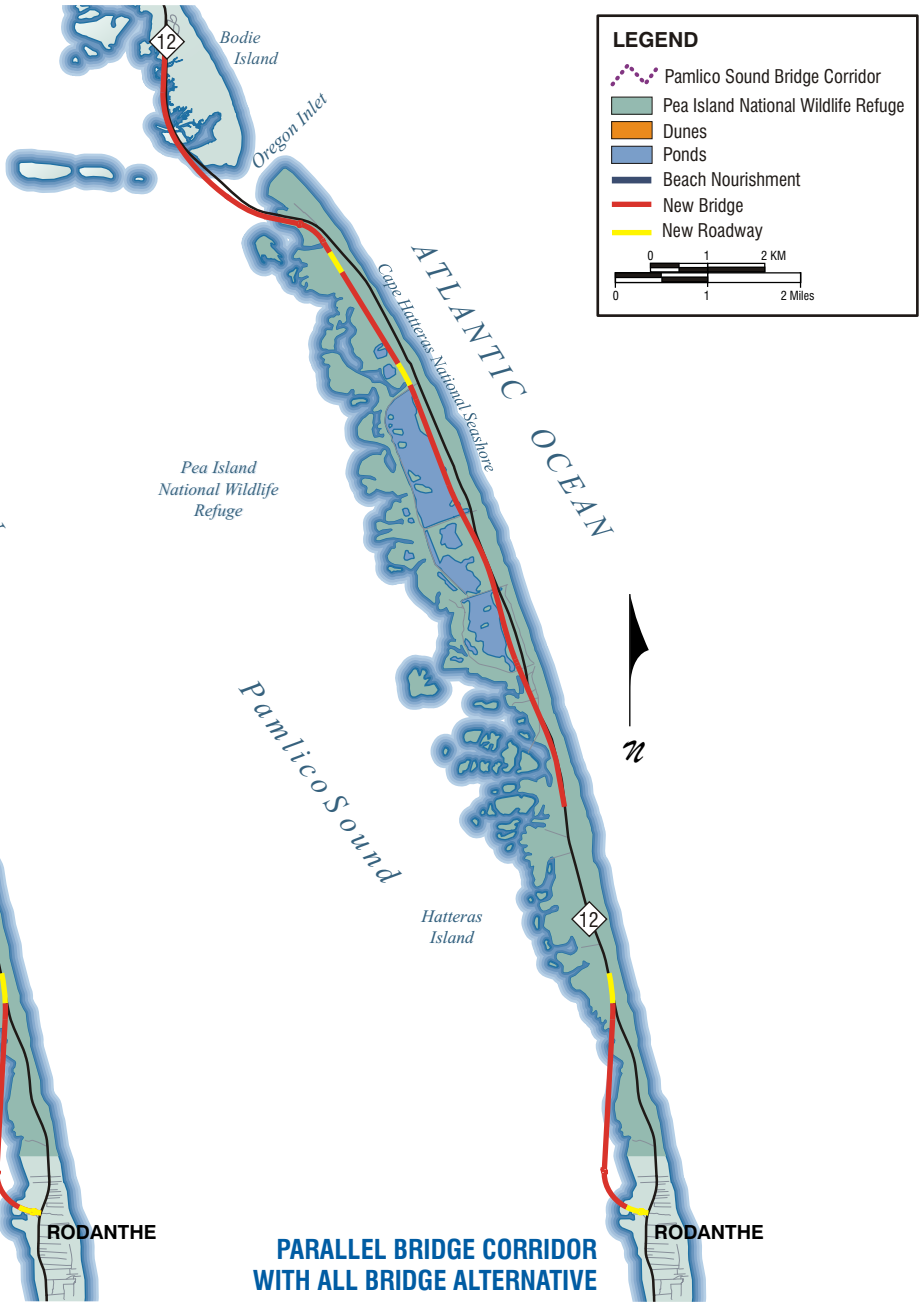
PAMLICO SOUND BRIDGE CORRIDOR

PARALLEL BRIDGE CORRIDOR WITH NOURISHMENT ALTERNATIVE



What other alternatives did you consider and why are they not preferred?

Numerous alternatives were studied throughout the course of this project. The Final Environmental Impact Statement (FEIS) documents the analysis and comparison of seven alternatives within two corridors: the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor (see maps).



The two Pamlico Sound Bridge Corridor alternatives would both involve building a new 17.5 mile bridge through Pamlico Sound, extending as far as 5 miles west of Hatteras Island, starting at the northern terminus of Bonner Bridge and connecting back into existing NC 12 in Rodanthe. The two alternatives only differ in the way they connect to NC 12 in Rodanthe (see inset map). One bridge alternative would curve into NC 12, and bridge traffic would simply merge with NC 12. The other bridge alternative would intersect with NC 12, and bridge users would turn right at a "T" intersection to continue on NC 12.

Five Parallel Bridge Corridor alternatives were studied:

- The **Nourishment Alternative** would maintain NC 12 in its current location, through the Refuge and into Rodanthe, by the implementation of beach nourishment and dune enhancement.
- The **Road North/Bridge South Alternative** would place NC 12 on a bridge west of Hatteras Island between northern Rodanthe and the southern part of the Refuge. In the northern part of the Refuge, NC 12 would be relocated onto an at-grade road to the west of the forecast 2060 high erosion shoreline.
- The **All Bridge Alternative** would include the same bridge as the Road North/Bridge South Alternative in northern Rodanthe and the southern part of the Refuge; but would relocate NC 12 on a bridge

PARALLEL BRIDGE CORRIDOR WITH ROAD NORTH/BRIDGE SOUTH ALTERNATIVE

PARALLEL BRIDGE CORRIDOR WITH ALL BRIDGE ALTERNATIVE

to the west of the forecast 2060 high erosion shoreline through the northern section of the Refuge.

- The two **Phased Approach Alternatives** (see map on page 6) would both maintain NC 12 in its current location in the Refuge and northern Rodanthe by elevating NC 12 onto bridges in phases. However, the alternatives differ in the Rodanthe area. The Preferred Alternative **(Phased Approach/Rodanthe Bridge)** assumes NC 12 is elevated into Rodanthe. The other alternative **(Phased Approach/Rodanthe Nourishment)** assumes that NC 12 is maintained in its existing location through northern Rodanthe by beach nourishment at the southern end of the Refuge and in the northern part of Rodanthe.

Various potential Oregon Inlet crossing alternatives were considered in early studies and found not to merit detailed analysis. These early alternatives included the feasibility of rehabilitating Bonner Bridge, replacing Bonner Bridge with ferry service, building a tunnel, and several other locations for the bridge replacement and NC 12 relocation.

The decision to select the Phased Approach/Rodanthe Bridge Alternative as the Preferred Alternative was made after careful consideration of the advantages and disadvantages of all the alternatives. Key considerations included environmental impacts, Refuge impacts, relocations of homes and businesses, constructability, future coastal conditions, funding, and federal law. Many of the environmental resource and regulatory agencies preferred the Pamlico Sound Bridge Corridor, but it was found to be not practical because of the unavailability of funds for a single project of such a large magnitude built in a single phase. The Preferred Alternative was selected primarily because it could be built in phases, making it affordable, and because it would not use land from the Refuge by remaining in the existing NC 12 easement. All other Parallel Bridge Corridor alternatives used Refuge lands outside the NC 12 easement.

Project Impacts

What are the environmental impacts of the Preferred Alternative?

In the Cape Hatteras National Seashore?

The Preferred Alternative would require the permanent use of 6.3 acres of the Seashore on Bodie Island for permanent fill and right-of-way over land. The existing Bonner Bridge also uses approximately 6.3 acres of land on Bodie Island. Land within the Seashore currently occupied by Bonner Bridge would be returned to the Seashore after the bridge is demolished and removed.

Construction activities for the Preferred Alternative also may require dredging, a haul road, and/or a work bridge within the portions of the Seashore in Pamlico Sound.

Visitors enjoy the beach at Cape Hatteras National Seashore

In the Pea Island National Wildlife Refuge?

Storm-related NC 12 maintenance for the existing roadway would continue, but in progressively fewer locations, until all phases of the Preferred Alternative are completed. Once complete, the bridges would be a sizable new linear man made feature for approximately 10 miles within the Refuge. The Preferred Alternative would be built and maintained within the existing NC 12 easement through the Refuge, so no new Refuge lands would be used. The Refuge's remaining undisturbed beaches would naturally erode, thereby altering the shoreline and wildlife currently using that habitat.

While paved road access would continue through the Refuge with the Preferred Alternative, only two public access points would be maintained (one at the north end and a second south of the ponds). Ultimately, bridge piles in the ocean could change the types of fish that congregate around the shore. Other activities on the beach front also would be affected, but not precluded, by the presence of the bridge and bridge piles in areas where the Preferred Alternative would be over the beach. Once the bridge piles are in the ocean, surfing and other recreational ocean activities would be adversely affected, but not eliminated, in those areas.

In Rodanthe?

The Preferred Alternative would extend approximately 1.1 miles south of the Refuge boundary into Rodanthe. Access to homes and several local businesses in northern Rodanthe along NC 12 would be provided via one-way frontage roads on either side of the bridge instead of directly from NC 12 (see example on page 5).

The Preferred Alternative would have a sizable visual effect on Rodanthe, introducing into views an elevated roadway for 1.1 miles. The elevated structure would impede the views of people on the sound-side of NC 12 looking east towards the Atlantic Ocean, as well as people on the ocean-side of NC 12 looking west. Views could be blocked by the elevated structure as high as the third or fourth story of residences, and it would be a dominating presence at ground level, particularly for the approximately 90 homes and businesses along NC 12 that would be within 100 feet of the new bridge.

Although two homes and one commercial building would be displaced by the construction of the Preferred Alternative, potential relocation sites exist within the project area. In addition, gas pumps located along NC 12 at the Liberty service station and the North Beach Beach Mart convenience store would be displaced.

What is NCDOT's Property Acquisition and Relocation Process?

Private property in the path of the Preferred Alternative will be purchased by the NCDOT. NCDOT pays fair market value for all property purchased. Third-party, licensed real estate appraisers determine a fair market value at the time of purchase. This is the same type of appraisal that is required when selling, buying, or refinancing a property.

Renters and homeowners who are relocated by the project have access to several programs to minimize the inconvenience of relocation: relocation assistance, relocation moving pavements, and relocation replacement housing payments of rent supplements. At least one relocation officer will be assigned to assist homeowners, renters, and owners of displaced businesses to search for and move to replacement property.

For more information regarding the right-of-way acquisition and relocation processes, please contact NCDOT's Division 1 Right-of-Way Office in Ahoskie at (252) 332-8182.

To historic resources?

At the former Oregon Inlet US Coast Guard Station (listed on the National Register of Historic Places), the greater height of the Preferred Alternative would alter the historic view and setting of the station.

The historic views and setting of the Chicamacomico Life Saving Station and several nearby houses that form the National Register-eligible Rodanthe Historic District would be altered with the Preferred Alternative.

The elevated structure of the Preferred Alternative would cause a sizable visual impact on the historic landscape of the Refuge, and would also lead to a loss of access to some Refuge facilities and natural features.

To recreational opportunities?

Charter fishing boats operating out of the Seashore's Oregon Inlet Marina and Fishing Center would not be able to use the channel known as "the crack," adding about 30 minutes to the time it currently takes to travel from the fishing center to the ocean.

Chicamacomico Life Saving Station

Former Coast Guard Station at Oregon Inlet

The popular catwalks on Bonner Bridge are not part of the replacement bridge, which would be approximately three times higher. However, options remain for retaining fishing access at Oregon Inlet.

Bridge piles in the ocean off Hatteras Island and along the beach would adversely affect, but not eliminate, beach front activities such as fishing, hiking, surfing, wind surfing, kite boarding, swimming, ocean kayaking, and birding.

Opportunities to stop and park for ocean and beach access would be limited to two locations: at the north end of the Refuge and south of the ponds.

To coastal change?

With the Preferred Alternative's new crossing over the Oregon Inlet, future dredging operations in the channel would be easier to undertake and could be reduced in frequency and magnitude.

The Preferred Alternative's use of elevated bridges, instead of roadway on fill, would allow natural channel flow and minimize coastal impacts caused by maintenance and artificial stabilization. As the shoreline naturally erodes, by 2060, most of the NC 12 bridges associated with the Preferred Alternative would be in the ocean.

When exposed to waves, tides, and storm events, the presence of the Preferred Alternative's bridge piles would alter the flow pattern around the piles, resulting in scour, effects on cross-shore transport during storm events, formation of additional rip currents, and changes in beach erosion and accretion patterns.

Hot Spots on NC 12

Rodanthe view from America Drive North

To natural resources?

During construction of the Preferred Alternative, construction barge traffic, fill and pile placement, and construction channel dredging would cause short-term water quality impacts. Long-term impacts to water quality include highway runoff that may contribute pollution to nearby ecosystems. The NCDOT would incorporate Best Management Practices (BMPs) applicable to controlling bridge deck runoff for all project segments traversing the receiving water bodies.

The Preferred Alternative would fill approximately 16.2 acres of biotic communities, including 3.1 acres of jurisdictional areas (0.5 acre of wetland and 2.6 acres of open water). Temporary traffic maintenance roads also would cause 48.5 acres of temporary biotic community impact, including 12.5 acres of temporary wetland impact. The habitat affected by the completed bridges would change over time as the shoreline erodes under the bridges. The maximum length of bridge over the ocean would be 8 miles in 2060. The maximum length of bridge over beach habitat would be 3.3 miles in 2020.

Most of the impact to essential fish habitat with the Preferred Alternative would be temporary, localized, and associated with bridge construction, leading to increased turbidity, noise, and siltation. Some permanent loss or alteration of essential fish habitat would result directly from shading and pile placement.

The Preferred Alternative would likely result in adverse impacts to four of the 13 protected species in Dare County: piping plover, leatherback sea turtle, green sea turtle, and loggerhead sea turtle. The Preferred Alternative also would likely result in adverse impacts to the proposed critical habitat north of Oregon Inlet for wintering piping plovers.

Loggerhead turtle (with transmitter)

To utilities?

Telephone and electrical lines on Bonner Bridge would be relocated to the new bridge. Those along NC 12 on Hatteras Island would need to be moved one or more times by 2060 in response to shoreline erosion.

What commitments does NCDOT intend to make to minimize impacts?

NCDOT is making numerous design and construction commitments for the project in order to minimize impacts. The list below is not a comprehensive list of the Project Commitments, but includes several thought to be of particular interest to the public. Please see the Project Commitments sheets printed on green paper in the FEIS for a complete list of the Project Commitments.

Design-Related Commitments

- All bridges will accommodate bicycles via 8-foot shoulders on both sides of the bridge and bicycle-safe bridge rails.
- Design and construction will be coordinated with utility providers in the project area in order to prevent interruption of local utility services.

Water Quality/Threatened and Endangered Species Commitments

- Protect water quality during construction by the use of Best Management Practices (BMPs) for sedimentation and erosion control measures.
- Minimize sediment clouding the water (turbidity), when possible and practicable, by working from temporary bridges and using BMPs for storage and disposal of construction and demolition materials.
- Construction contracts would require compliance with USFWS guidelines for avoiding construction impacts to the West Indian Manatee.
- NCDOT will comply with NMFS guidelines that restrict in-water construction-related activities when sea turtles and smalltooth sawfish are observed in the project area.
- Implement conservation measures to protect shortnose sturgeon, including no hopper dredging and measures to minimize habitat degradation.
- Survey the project area for seabeach amaranth habitat at least one year prior to initiating bridge construction activities, and re-survey, as needed, for each construction phase of the Preferred Alternative.
- Based on conditions specified by the USFWS related to protecting piping plovers and sea turtles, the NCDOT will implement design and construction measures to:

- **Piping plover** – avoid disturbing nesting piping plovers; to the extent possible, avoid disturbing foraging and roosting plovers; and avoid or minimize opportunities for avian predator perches.

- **Sea turtles** – avoid disturbing nesting sea turtles, nests, and hatchlings; educate construction contractors and pertinent

What is Design-Build?

The NCDOT's Design-Build Program affords NCDOT with a powerful tool to deliver appropriate projects in an expedited and value-driven manner. NCDOT personnel, across various disciplines and divisions, work in concert to select, develop, and administer projects conducive to the design-build method of contracting.

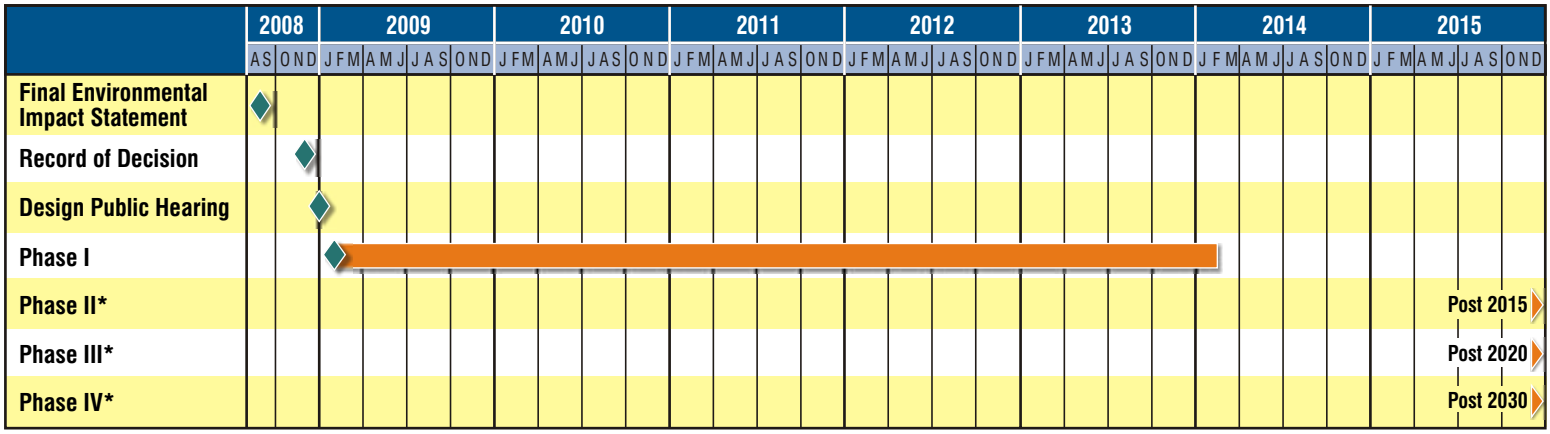
The design-build process combines into a single contract the final design and construction services necessary to construct a project. Design-build projects allow contractors to participate in design and designers to participate in constructability issues. This interaction allows designers and contractors to marry their expertise and resources to best suit a specific project. The resulting integration of design and construction typically expedites construction, facilitates environmental responsibility and permitting, and may reduce overall project delivery costs. Design-build contracting is implemented in accordance with NCDOT and other specifications and standards.

NCDOT staff as to the adverse effects of artificial lighting on sea turtles; minimize the effects of construction lighting on nesting sea turtles and hatchlings; minimize the effects of vehicle headlights from the completed bridge; and avoid permanent light fixtures.

Construction Commitments

- If any historic archaeological resources are uncovered, stop any construction work affecting the resource until the resource can be identified and assessed for eligibility for the National Register of Historic Places.
- Work with NPS and USFWS to determine areas near project construction where night lighting would need to be avoided or limited. During turtle nesting season (May 1 to November 15), night lighting will meet conditions specified by the USFWS to protect sea turtles. Night lighting also would not be used close to areas where people sleep, including the campground at the northern end of the project area and the Rodanthe area at the southern end.
- Implement a coastal monitoring program on Hatteras Island within the project area, the particulars of which would be developed in association with representatives of the Refuge, in order to make decisions related to the future implementation of Phases III and IV.

How do the impacts of the Preferred Alternative compare with the impacts of other alternatives considered?



The table on page 13 presents a summary comparison of the seven detailed study alternatives considered. Presented is information related to: construction, social, economic, and cultural impacts (i.e., alternative cost and length, business and residential relocations, community impacts, cultural resources impacts, and utility impacts); Refuge and coastal conditions impacts (i.e., Refuge access, fishing access, use of Refuge land, visual impacts, potential for storm-related breaches of NC 12, and economic impact of a breach); and natural resources impacts (i.e., biotic communities and protected species impacts).

What happens next and when will the replacement of Bonner Bridge with a new bridge over Oregon Inlet be completed?

Next steps are presented in the timeline below. Following the release of the FEIS, comments may be submitted to NCDOT for 30 days. Public review locations and an address for sending comments are included on page 14 of this summary and in the FEIS. At the end of the period, NCDOT will release a Record of Decision (ROD), which will affirm the Preferred Alternative as the alternative selected for implementation and respond to any comments on the FEIS. Once the ROD is released, NCDOT can proceed with letting a contract for the design and construction of Phase I, the Bonner Bridge replacement over Oregon Inlet.

The construction contract for Phase I, the replacement of Bonner Bridge, will be awarded in 2009. Phase I is expected to be completed in 2014. The NCDOT plans to build the new Oregon Inlet bridge as a "Design-Build" project (see inset above for further information on Design-Build).

PROJECT TIMELINE (as of August 2008)

These dates are preliminary. Construction of Phases II to IV will be completed as soon as it is practicable.

COMPARISON OF ALTERNATIVES

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/ Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge (Preferred Alternative)	Phased Approach/ Rodanthe Nourishment
Construction, Social, Economic, and Cultural Impacts							
Total Highway Cost through 2060 (in millions of 2006 dollars)*	$1,305.6 - $1,797.6	$1,299.1 - $1,788.1	$671.8 - $970.4	$602.2 - $740.2	$1,107.7 - $1,435.3	$1,171.5 - $1,497.1	$1,149.1 - $1,524.4
Length (miles)	18.0	17.8	15.9	16.0	15.9	16.0	15.2
Residential Relocations	6	5	0	2	2	3	0
Business Relocations	6	1	0	0	0	1 plus two partially affected	0
Rodanthe Community Cohesion, Accessibility, and Visual Impacts	Views of Pamlico Sound from homes along shoreline in Rodanthe would be affected.		None	Views of Pamlico Sound from homes along shoreline in Rodanthe would be affected.		1 mile of bridge would bisect community; access more circuitous; views in Rodanthe affected.	0.3 mile of bridge would bisect community; access more circuitous; views in Rodanthe near the Refuge affected.
Cultural Resources with Adverse Effect	1 - (former) Oregon Inlet US Coast Guard Station			3 - Refuge, (former) Oregon Inlet US Coast Guard Station, and Rodanthe Historic District and Chicamacomico Life Saving Station			2 - Refuge and (former) Oregon Inlet US Coast Guard Station
Cost to Relocate Utilities (in millions)	$53.9		$12.1	$15.0	$17.4	$17 4	$17.4
Refuge and Coastal Conditions Impacts							
General Refuge Access	Likely loss of the paved road within the Refuge. USFWS would need to provide alternate access.		Little change in access. Refuge facilities protected from future beach erosion.	Paved road access maintained but with some changes.	Access focused on three points; direct access to some Refuge facilities lost.	Access focused on two points; direct access to some Refuge facilities lost.	
Refuge Fishing Access	No fishing catwalks at north end of Hatteras Island. No paved road access to other fishing locations in Refuge.		No fishing catwalks; alternate access possible; beach fishing access unaffected.	No fishing catwalks; alternate access possible; beach fishing access maintained except at southern end.	No fishing catwalks; alternate access possible; beach fishing access limited to 3 locations.	No fishing catwalks; alternate access possible; beach fishing access limited to 2 locations.	
Use of Refuge Land Outside of Existing Easement (acres)	No use.		19.9 acres used primarily for new dunes plus periodic nourishment of 6.3 miles of seashore.	93.4 acres used primarily for new highway easement.	92.2 acres used primarily for new highway easement.	No use, project contained within existing highway easement.	Minor amount used for periodic nourishment of 1,500 feet of seashore; generally contained within existing highway easement.
Visual Impacts	None		Minimal; associated with limited new dunes.	Low	Sizable visual intrusion into the landscape of the Refuge.		
Potential for Breach and Need for Closing Breach to Maintain NC 12	Eliminates breach concerns by bypassing the Refuge. No need to close future breaches.		Nourishment would reduce the risk of a breach. Any breaches through the Refuge would need to be closed.	Breaches in northern portions of the Refuge would need to be closed; a deep breach near the terminal groin could be difficult to fill with sand.	Potential breach areas bridged. No need to close future breaches.	Potential breach areas bridged. Phases II and III may need to be accelerated, if a breach occurred before all four phases are completed.	
Economic Impact of a Breach	Not applicable.		Economic impact (reduction in retail sales) of a breach open for three months would be $5.7, $46.3, and $146.7 million in the off-peak, middle, and peak season; jobs and tax revenue also would be lost.				
Natural Resources Impacts							
Biotic Communities Impacts (acres)							
Submerged Aquatic Vegetation (SAV)	0.31	0.30	0.20	1.40	1.40	0.20	0.20
Wetlands	1.84	1.18	1.68	50.74	6.68	0.47	0.44
Uplands - Natural & Man Dominated	7.97	6.66	20.30	13.45	4.89	13.13	6.45
Impoundments	0.00	0.00	0.00	22.11	0.43	0.00	0.00
Aquatic Bottom	2.69	2.70	2.40	3.90	3.82	2.44	2.44
Total	**12.81**	**10.84**	**24.58**	**91.60**	**17.22**	**16.24**	**9.53**
Protected Species Adversely Affected							
Piping Plover	Not likely to adversely affect.		Likely construction/demolition disturbance to nesting; potential nesting, foraging, and roosting habitat lost.				
Leatherback Sea Turtle/Green Sea Turtle/Loggerhead Sea Turtle	Not likely to adversely affect.		Likely disturbance to nesting on beach; not likely to adversely affect in ocean.				
Seabeach Amaranth	Not likely to adversely affect.		Beach nourishment could impact habitat.	Not likely to adversely affect.			Beach nourishment could impact habitat.

**Total highway cost includes the new Oregon Inlet bridge, Bonner Bridge demolition, all costs associated with construction of NC 12 roads and bridges (Phases II to IV), removal of the existing NC 12 pavement, additional right-of-way on Bodie Island and in Rodanthe, wetland mitigation, and all operation and maintenance costs through 2060.*

Navigating the Final Environmental Impact Statement (FEIS)

The FEIS documents the purpose and need for the project; describes existing and projected conditions in the project area; identifies the seven detailed study alternatives in two corridors; and assesses the direct, indirect, and cumulative impacts of these alternatives, including community, visual, cultural resource, natural resource, and environmental quality considerations.

The public often finds the size and amount of information contained in an Environmental Impact Statement (EIS) overwhelming. The content of the document is dictated by the multiple interests it was written to serve. An EIS must provide information of interest to the general public, as well as that required by law and federal and state resource agencies and of concern to special interest groups.

When reviewing the FEIS, we suggest you begin with the Summary, which contains an overview of the contents and key issues within the FEIS. A detailed Table of Contents is presented next, which can help direct you to sections of particular interest to you. At the end of Volume 1, an index can help you locate discussions of specific topics. Following is a more detailed description of the content of some of the sections of the FEIS:

The section printed on green paper presents NCDOT's commitments to reduce potential environmental impacts during project construction and operation. These are commitments unique to this project and its setting. Many other routine commitments, such as replacement of wetlands lost and paying the relocation costs of people and businesses displaced, are noted as applicable throughout the FEIS.

Chapter 2 provides descriptions of the No-Action Alternative, the preliminary alternatives (e.g., tunnel, ferry, etc.), and the seven detailed study alternatives. Chapter 2 also discusses each alternative's ability to serve the project's Purpose and Need.

Chapter 3 describes the existing conditions in the project area. Topics include community resources, cultural resources, natural resources, air quality, and noise.

Chapter 4 contains the same or similar sections as Chapter 3, but discusses the project's potential direct, indirect, and cumulative impacts with respect to each of these topics.

Chapter 5 is the Section 4(f) Evaluation. This evaluation is required because the Preferred Alternative would use land from the Seashore on Bodie Island. FHWA cannot approve the use of land from a significant publicly owned park, recreation area, or wildlife and waterfowl refuge without preparing a Section 4(f) Evaluation.

Chapter 6 lists the preparers of the document; **Chapter 7** lists locations where the document may be viewed as well as other agencies who receive a copy; and **Chapter 8** summarizes the public and agency comments on previous environmental documents and coordination performed over the course of the project.

FEIS Review Locations

The proposed project is the construction of a bridge to replace Herbert C. Bonner Bridge in Dare County and demolition and removal of Bonner Bridge and improvements to NC 12 between the community of Rodanthe and Oregon Inlet. This FEIS documents the purpose and need for the project; describes existing and projected conditions in the project area; identifies seven alternatives in two corridors; and assesses the direct, indirect, and cumulative impacts of these alternatives, including community, visual, cultural resource, natural resource, and environmental quality considerations. Public and government agency comments on the SDEIS and SSDEIS also are addressed in this document.

Comments on this FEIS are due by _____ and should be sent to Gregory J. Thorpe, Ph.D. at the above address.

S.3 Brief Description of the Project

The North Carolina Department of Transportation (NCDOT) proposes to replace the Herbert C. Bonner Bridge across Oregon Inlet in Dare County. Bonner Bridge, built in 1962, is approaching the end of its reasonable service life. Bonner Bridge is a part of NC 12 and provides the only highway connection between Hatteras Island and Bodie Island. The replacement structure would serve the same function. The project also includes NC 12 between the community of Rodanthe and Oregon Inlet, an area that is at risk because of shoreline erosion. This project proposes to provide a long-term approach to minimizing that risk through 2060.

Two replacement bridge corridors are assessed in this Final Environmental Impact Statement (FEIS): the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor with NC 12 Maintenance. The proposed corridors are illustrated in Figure S-1. The alternatives associated with each corridor are:

- Pamlico Sound Bridge Corridor.
  - With Curved Rodanthe Terminus.
  - With Intersection Rodanthe Terminus.
- Parallel Bridge Corridor.
  - With Nourishment.

REPLACEMENT BRIDGE CORRIDORS AND PREFERRED ALTERNATIVE

Figure S-1

- With Road North/Bridge South.
- With All Bridge.
- With Phased Approach/Rodanthe Bridge (Preferred).
- With Phased Approach/Rodanthe Nourishment.

The Pamlico Sound Bridge Corridor contains a proposed Pamlico Sound bridge that would be approximately 17.5 miles (28.2 kilometers) in length. The total project length would be 18 miles (29.0 kilometers), including the bridge, as well as the approach roads at the northern and southern ends. The southern terminus of the project would be within the community of Rodanthe on Hatteras Island. Two possible termini design options are being evaluated in Rodanthe. With the Curved Rodanthe Terminus, the proposed bridge would end in a curve that would connect the bridge directly to NC 12. With the Intersection Rodanthe Terminus, the proposed bridge would end with a signalized intersection at NC 12. The bridge would extend north from Rodanthe into Pamlico Sound as much as 5 miles (8 kilometers) west of Hatteras Island. The project would end at the northern terminus of the Bonner Bridge on Bodie Island, within the Cape Hatteras National Seashore (the Seashore).

The typical section for a Pamlico Sound bridge would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders. This bridge's Oregon Inlet navigation spans would provide a minimum navigation opening of 200 feet (61 meters) horizontally and 75 feet (23 meters) vertically. The navigation zone (area with spans of the navigation span height and width) would be 1,600 to 2,000 feet (488 to 610 meters) long. The proposed typical bridge span outside the navigation zone would be 140 to 150 feet (42.7 to 45.7 meters) long. The location(s) of navigation span(s) would be considered when designing for potential vessel collision. Outside the navigation zone, the vertical clearance of the bridge currently is proposed to be approximately 10 feet (3.1 meters) above mean high water. A project in the Pamlico Sound Bridge Corridor would cost approximately $1.3 to $1.8 billion (including construction cost, right-of-way cost, operation and maintenance costs until 2060, and other highway-related costs in 2006 dollars) by 2060, with the initial bridge costs ranging between $929.1 million and $1.4 billion.

The Parallel Bridge Corridor (including the Preferred Alternative) contains a proposed Oregon Inlet bridge that would be up to 3.2 miles (5.1 kilometers) in length. The NC 12 maintenance component would keep NC 12 open from the community of Rodanthe to the Oregon Inlet bridge's southern terminus, a distance of approximately 12.5 miles (20.1 kilometers). The NC 12 maintenance component would pass through the Pea Island National Wildlife Refuge (the Refuge), which has shared jurisdiction with the Seashore.

The Nourishment Alternative assumes that NC 12 would remain in its current location, and beach nourishment combined with dune enhancement would be used to maintain an adequate beach and dune system. The total length of beach requiring regular nourishment would be approximately 6.3 miles (10.1 kilometers). Nourishment would occur in four locations, likely repeated at four-year intervals.

With the Road North/Bridge South Alternative, NC 12 would be placed on a bridge west of Hatteras Island beginning at a new intersection in Rodanthe and continuing to a point approximately 2 miles (3.2 kilometers) north of the Refuge's southern boundary where the project would meet existing NC 12. NC 12 would then remain unchanged for 2.6 miles (4.2 kilometers). Beginning at a point approximately 1.3 miles (2.1 kilometers) south of the Refuge's ponds,

NC 12 would be relocated to a point 230 feet (70.1 meters) west of the forecast 2060 high erosion shoreline. This relocation would continue 7.1 miles (11.4 kilometers) north until the relocated NC 12 would meet the Oregon Inlet bridge. Three 10-foot-high (3-meter-high) dunes, totaling 2,100 feet (640 meters) in length would be built adjacent to the relocated road, but not immediately. They would be built when needed as the shoreline erodes towards the relocated road. The first one is not expected to be needed until 2030.

The All Bridge Alternative would include the same bridge in the Rodanthe area as the Road North/Bridge South Alternative. In the central and northern part of the Refuge, NC 12 would be constructed on a bridge to the west of the existing road. Two road segments would be included in this relocation, one near Oregon Inlet and one just north of the Refuge's ponds, where access from NC 12 to the Refuge would be provided. Access to the Refuge also would be available in a 1.8-mile (2.9-kilometer) section of NC 12 that would be left unchanged between the Rodanthe area bridge and the beginning of the next bridge section south of the ponds. The bridges associated with this alternative would span the five potential storm-related island breach locations.

The Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) assume an Oregon Inlet bridge, as well as elevating portions of NC 12 through both the Refuge and northern Rodanthe within the existing NC 12 easement. The alternatives would be built in four phases, with the first phase being the bridge across Oregon Inlet. Additional phases would be built as necessitated by coastal conditions. Two southern termini are considered: the Phased Approach/Rodanthe Bridge Alternative (Preferred) and Phased Approach/Rodanthe Nourishment Alternative. With the Phased Approach/Rodanthe Bridge Alternative (Preferred), the bridge in the existing NC 12 easement would begin in Rodanthe just north of Sudie Payne Road (see Figure 2-21) and extend north to Oregon Inlet except for the 2.1 mile (3.4-kilometer) length of NC 12 in the southern half of the Refuge that would not be threatened by erosion prior to 2060. Access to properties adjacent to the bridge in Rodanthe would be provided by a one-lane, one-way frontage road on each side of the NC 12 bridge. The Phased Approach/Rodanthe Nourishment Alternative would be similar, except the southern end of the NC 12 bridge would begin 0.3 mile (0.5 kilometer) south of the Refuge/Rodanthe border. Beach nourishment would be used to protect NC 12 in Rodanthe.

The typical section for the Oregon Inlet bridge in the Parallel Bridge Corridor (including the Preferred Alternative) would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders. The bridge would include a series of navigational spans across Oregon Inlet. This "navigation zone" for three of the Parallel Bridge Corridor alternatives would be up to 5,000 feet (1,524 meters) long, with a vertical clearance of approximately 75 feet (22.9 meters); however, the two Phased Approach alternatives (including the Preferred Alternative) include a navigation zone 3,300 feet (1,006 meters) in length. The shorter distance with the two Phased Approach alternatives (including the Preferred Alternative) is necessitated by the inclusion of ramps to provide access to the north end of Hatteras Island from the alternatives' bridges. Spans within the navigation zone would provide 200 feet (61 meters) of horizontal clearance.

The bridges associated with the Road North/Bridge South Alternative, the All Bridge Alternative, and the Phased Approach alternatives (including the Preferred Alternative) would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders. The typical bridge span would be 100 to 120 feet (30.5 to 36.6 meters). The vertical clearance of bridges over land to the west of existing NC 12 with the Road North/Bridge South and All Bridge alternatives is assumed to be a minimum of approximately 10 feet (3.1 meters) above mean high water. The vertical clearance with the two Phased Approach alternatives (including the Preferred Alternative) is

assumed to be 25 feet (7.6 meters) above mean high water. This height assumes the flat storm surge elevation, plus the wave height, plus some additional clearance. The typical section of relocated roadway (for the Road North/Bridge South and All Bridge alternatives) would have two 12-foot (3.6-meter) travel lanes with 8-foot (2.4-meter) shoulders (4-foot [1.2-meter] paved). The total costs through 2060 (including construction, right-of-way, operation and maintenance, and other) (in 2006 dollars) for the alternatives in the Parallel Bridge Corridor would be an estimated: $671.8 to $970.4 million (Nourishment), $602.2 to $740.2 million (Road North/Bridge South), $1.1 to $1.4 billion (All Bridge), and $1.1 to $1.5 billion (Phased Approach, including the Preferred Alternative). These costs include a range of $260 to $347 million for an Oregon Inlet bridge. Cost estimates will be revisited in the context of design prior to the implementation of each phase.

Bonner Bridge would be demolished at an estimated cost of about $4 million (2006 dollars).

Full descriptions of the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are presented in Sections 2.9 and 2.10, respectively. Cost estimates for all alternatives and other associated public costs are presented in Section 2.12.

On August 27, 2007, representatives of NCDOT, the Federal Highway Administration (FHWA), the US Army Corps of Engineers (USACE), and the North Carolina Department of Environment and Natural Resources (NCDENR) identified the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) as the Least Environmentally Damaging Practicable Alternative (LEDPA) for this project as part of the interagency National Environmental Policy Act (NEPA)/Section 404 Merger Process. The LEDPA was adopted as the project's Preferred Alternative (see Figure S-1). The Phased Approach/Rodanthe Bridge Alternative (Preferred) proposes replacing the Bonner Bridge with a bridge parallel to and west of Bonner Bridge, as well as maintaining NC 12 from the community of Rodanthe to Oregon Inlet by building additional bridges as needed within the existing NC 12 easement. This decision was based on: the ability of the alternatives considered to meet the project's purpose and need; environmental consequences; opportunities available to mitigate impacts; cost; public and agency comment on the findings of the Supplemental Draft Environmental Impact Statement (SDEIS) and the 2007 Supplement to the Supplemental Draft Environmental Impact Statement (SSDEIS); and other findings presented in this FEIS.

S.4 Other Proposed Actions

This project is included as TIP Project No. B-2500 in the NCDOT's *2009 to 2015 State Transportation Improvement Program* (TIP) covering the period from Federal Fiscal Year (FFY) 2009 (October 2008) through FFY 2015 (September 2015). The additional transportation projects that are near the proposed project are depicted in Figure 1-1 and listed below:

Project R-3116A	Planning for interim measures to protect NC 12 from sand and ocean overwash at Ocracoke Island.
Project R-3116B	Planning for interim measures to protect NC 12 from sand and ocean overwash at Hatteras Village.

Project R-3116D*	Relocation of NC 12 from north of Rodanthe to south of the Refuge Boundary (Rodanthe 'S' Curves Hot Spot) to protect roadway from sand and ocean overwash.
Project R-3116E*	Planning for interim measures to protect NC 12 from sand and ocean overwash at the Sandbag Area Hot Spot.
Project R-3116F*	Planning for interim measures to protect NC 12 from sand and ocean overwash at the Canal Zone Hot Spot. (This project is combined with Project R-3116E for planning purposes.)
Project R-3116H	Planning and environmental studies for the long-term maintenance of NC 12 from Ocracoke Island to the southern terminus of Bonner Bridge. A joint NCDOT/USACE feasibility study (Hatteras and Ocracoke islands, NC) was underway but is currently not funded by the US Congress.
Project R-4070B	Planning and environmental studies for maintaining NC 12 from Buxton to Avon. Programmed for planning and environmental studies only.
Project B-5014	Repairs to Bridge No. 11 (Bonner Bridge over Oregon Inlet) in FFY 2007 and FFY 2008.

* Project not listed in the TIP and is currently unfunded. Planning studies were underway, but they are currently (2008) on hold and are not expected to be implemented given that the Phased Approach/Rodanthe Bridge Alternative (Preferred) is a long-term solution to protecting NC 12 from sand and ocean overwash.

The replacement of Bonner Bridge is not dependent on the completion of any of the above projects.

S.5 Other Alternatives Considered

Six alternatives studies were completed over the course of the project, which ultimately yielded the seven alternatives evaluated in detail in the SDEIS (five alternatives), SSDEIS (two alternatives), and this FEIS. This section lists those studies, the alternatives considered, and their outcome. Full descriptions of each study are presented in Chapter 2 of this FEIS in the sections indicated below. The studies were:

- 1991 Feasibility Study and 1993 Draft Environmental Impact Statement Alternatives. This work considered the following alternatives:
  - Transportation Systems Management (TSM);
  - Rehabilitate Existing Bridge;
  - Ferry;
  - Tunnel;
  - East Bridge Corridor;

- West Bridge Corridor; and
- Parallel Bridge Corridor.

The 1993 Parallel Bridge Corridor was assessed in the 1993 DEIS as the preferred corridor and was selected by the NCDOT as the preferred alternative for implementation following public hearings in February 1994. See the full discussion of this study in Section 2.2.

Beach erosion, however, increased problems with ocean overwash along NC 12 south of Bonner Bridge, and regulatory requirements for the Refuge changed in accordance with the National Wildlife Refuge System Improvement Act of 1997 (see Section 3.5). Thus, the 1993 Parallel Bridge Corridor is now being considered in conjunction with a long-term strategy for NC 12 maintenance through the Refuge.

- 2002 Corridor Alternatives Study. Additional replacement bridge corridor alternatives were studied in 2002 because of the changed conditions in the project area and changed regulatory requirements. Alternatives assessed involved several different ending points on Hatteras Island and different corridor locations in Oregon Inlet and Pamlico Sound. Alternative 4 (redesignated the Pamlico Sound Bridge Corridor) was selected for detailed study in the SDEIS and this FEIS in the context of this study. The other alternatives studied were:
  - Alternative 1a;
  - Alternative 1b (wide);
  - Alternative 1b (close);
  - Alternative 1c;
  - Alternative 2 (wide);
  - Alternative 2 (close);
  - Alternative 3 (wide); and
  - Alternative 3 (close).

  See the full discussion of this study in Section 2.3.

- 2003 Alignment Alternatives Study. Bridge alignment alternatives within the Pamlico Sound Bridge Corridor were studied in 2003. They varied by their position in Pamlico Sound and the manner in which they terminated in the community of Rodanthe on Hatteras Island. Of the alternatives studied, Alignments A and C were selected for detailed study in the SDEIS and FEIS and were redesignated as the Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus Alternative and the Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus Alternative, respectively. Other alternatives studied were:
  - Alignment B;
  - Alignment D;

- Alignment E; and
- Alignment F.

See the full discussion of this study in Section 2.4.

- 2004 Additional Replacement Bridge Scenarios. The Dare County Commissioners indicated concerns about the implementation of a Pamlico Sound Bridge Corridor Alternative, preferring a replacement bridge that ends near the south terminus of Bonner Bridge and connects to existing NC 12. They also requested the consideration of long span bridges. Five additional replacement bridge scenarios using long span bridges were considered:
  - Multiple Cable-Stayed;
  - Single Span Cable-Stayed;
  - Suspension; and
  - Multiple Arch Bridges.

  None of these alternatives were selected for detailed study in the SDEIS and FEIS. See the full discussion of this study in Section 2.5.

- 2005 Parallel Bridge Corridor with NC 12 Maintenance Alternative Studies. In 2005, it was decided to evaluate the Parallel Bridge Corridor with NC 12 Maintenance Alternative in detail in the SDEIS and this FEIS. These alternatives end the replacement bridge at the north end of Hatteras Island and include long term solutions to keeping NC 12 open from the community of Rodanthe to Oregon Inlet through 2060. In the context of this study, the Parallel Bridge Corridor with Road North/Bridge South (called Relocate Road North [West of 2060 Shoreline]/Bridge South in this study), All Bridge, and Nourishment alternatives were selected for detailed study. Other alternatives examined during this study were:
  - Nourishment North/Bridge South;
  - Relocate Road North (West of Ponds)/Bridge South; and
  - Relocate Road North (West of 2060 Shoreline)/Interim Road then Bridge South.

  See the full discussion of this study in Section 2.6.

  2006 Parallel Bridge Corridor with Phased Approach Alternatives Studies. Two detailed study alternatives— Phased Approach/Rodanthe Bridge Alternative (Preferred) and Phased Approach/Rodanthe Nourishment—came out of this study. No other alternatives were considered during this study. See the full discussion of this study in Section 2.7.

S.6 Major Environmental Impacts and Costs

A detailed presentation of the environmental impacts of the alternatives selected for detailed study is presented in Chapter 4. A full description of the existing community, visual, cultural, natural, and other resources in the project area is presented in Chapter 3, including graphics that illustrate the resources' locations in the project area. The following sections summarize the major

environmental impacts associated with the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor with NC 12 Maintenance (including the Preferred Alternative). Key differences are summarized in Table S-1.

Community

The Pamlico Sound Bridge Corridor with the Curved Rodanthe Terminus would displace six businesses and six homes. The Pamlico Sound Bridge Corridor with the Intersection Rodanthe Terminus would displace one business and five homes. The Parallel Bridge Corridor with Nourishment and the Phased Approach/Rodanthe Nourishment alternatives would result in no displacements, while the Road North/Bridge South and All Bridge alternatives would displace no businesses and two homes. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would displace two homes and a commercial building that contains a business and a residence. Based on coordination with Realtors in the project area, adequate relocation housing and business sites exist. In addition, the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would displace the gas pumps closest to NC 12 at the Liberty service station, as well as the gas pumps at the North Beach Beach Mart and Campground convenience store in Rodanthe.

The Pamlico Sound Bridge Corridor alternatives would be consistent with the *Dare County Land Use Plan* and zoning, the Coastal Area Management Act (CAMA), and National Park Service (NPS) plans. Although the Pamlico Sound Bridge Corridor alternatives would bypass the portion of the Seashore north of Rodanthe and the Refuge, the USFWS and the NPS have indicated that they would intend to maintain some type of access within the Refuge and this portion of the Seashore for recreational users. However, the method of access likely would be something different than a paved road between Rodanthe and Oregon Inlet that is desired by Dare County officials. The *Pea Island National Wildlife Refuge Comprehensive Conservation Plan* indicates that this circumstance may necessitate changes in the current plan.

The Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be consistent with the *Dare County Land Use Plan* and zoning. However, the two Phased Approach alternatives (including the Preferred Alternative) may not be compatible with the principles of CAMA because they require the construction of permanent bridges in locations that are projected to eventually be on the beach and in the ocean. The NPS and US Fish and Wildlife Service (USFWS) will be responsible for determining whether or not the Phased Approach/Rodanthe Bridge Alternative (Preferred) is consistent with NPS plans and the Refuge's *Comprehensive Conservation Plan*, respectively. The Refuge's *Comprehensive Conservation Plan* assumes a bridge over Oregon Inlet and a maintained road in the existing NC 12 easement in the Refuge pending NCDOT's decisions on the replacement of Bonner Bridge and the long-term maintenance of NC 12. With the two Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) and the Nourishment Alternative, NC 12 would be retained in its existing easement through the Refuge, as assumed in the *Comprehensive Conservation Plan*.

With the exception of the Phased Approach/Rodanthe Bridge Alternative (Preferred), the alternatives in the Parallel Bridge Corridor could occur only if the USFWS concluded that alternative is compatible with the April 1938 Executive Order 7864, which reserved the Refuge to advance the purposes of the Migratory Bird Conservation Act, and the National Wildlife Refuge System Improvement Act of 1997. Without such a compatibility determination, the USFWS could not issue a permit for the construction of a project on new alignment within the Refuge or a long-term beach nourishment program. The Phased Approach/Rodanthe Bridge Alternative (Preferred), however, remains within the existing NC 12 easement. A compatibility determination is not required since the Preferred Alternative falls within the terms of the easement permit.

Table S-1. Comparison of Alternatives

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/ Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge Alternative (Preferred)	Phased Approach/ Rodanthe Nourishment
Community and Visual Impacts							
Residential Relocations	6	5	0	2	2	3	0
Business Relocations	6	1	0	0	0	1 plus two partially affected	0
Anticipated Need for Refuge Compatibility Determination	No Compatibility Determination required.		Compatibility Determination expected (for all alternatives that use Refuge lands outside the existing NC 12 easement).			No Compatibility Determination required.	Compatibility Determination expected (for all alternatives that use Refuge lands outside the existing NC 12 easement).
Economic Impact of a Breach in Hatteras Island	Not applicable.		Economic impact (reduction in retail sales) of a breach open for three months would be $5.7, $46.3, and $146.7 million in the off-peak, middle, and peak season; jobs and tax revenue also would be lost.				
Rodanthe Community Cohesion, and Accessibility	No impact.					1 mile (1.6 kilometers) of bridge would bisect community; access more circuitous.	0.3 mile (0.5 kilometer) of bridge would bisect community; access more circuitous.
Utilities Cost to Relocate (in millions)	$53.9		$12.1	$15.0	$17.4	$17.4	$17.4
Visual Impact	Views of Pamlico Sound from homes along shoreline in Rodanthe would be affected.		None	Views of Pamlico Sound from homes along shoreline in Rodanthe would be affected.	Sizable visual intrusion into the landscape of the Refuge; views of Pamlico Sound from homes along shoreline in Rodanthe would be affected.	Sizable visual intrusion into the landscape of the Refuge; views in Rodanthe affected.	Sizable visual intrusion into the landscape of the Refuge; views in Rodanthe near the Refuge affected.

Table S-1 (continued). Comparison of Alternatives

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	**Intersection Rodanthe Terminus**	**Nourishment**	**Road North/ Bridge South**	**All Bridge**	**Phased Approach/ Rodanthe Bridge Alternative (Preferred)**	**Phased Approach/ Rodanthe Nourishment**
Cultural Resource Impacts							
Cultural Resources with Adverse Effect	1 – (former) Oregon Inlet US Coast Guard Station			3 – Refuge, (former) Oregon Inlet US Coast Guard Station, and Rodanthe Historic District and Chicamacomico Life Saving Station			2 – Refuge and (former) Oregon Inlet US Coast Guard Station
Section 4(f) Resources Affected							
• (Former) US Coast Guard Station	No use.						
• Seashore on Bodie Island	7.3 acres (3.0 hectares) used		6.3 acres (2.6 hectares) used				
• Seashore on Hatteras Island and Refuge	No use.		19.9 acres (8.1 hectares) used primarily for new dunes plus periodic nourishment of 6.3 miles (10.1 kilometers) of seashore.	93.4 acres (37.8 hectares) used primarily for new highway easement.	92.2 acres (37.3 hectares) used primarily for new highway easement.	No use, project contained within existing highway easement.	Minor amount used for periodic nourishment of 1,500 feet (457 meters) of seashore; generally contained within existing highway easement.
• Rodanthe Historic District	No use.		No use.	Will use land from district passing 14 feet (4.3 meters) and 320 feet (97.5 meters) away from two contributing structures.		No use, contained within existing highway right-of-way within the district.	No use.

Table S-1 (continued). Comparison of Alternatives

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/ Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge Alternative (Preferred)	Phased Approach/ Rodanthe Nourishment
Parks and Recreation Impacts							
General Refuge Access	Likely loss of the paved road within the Refuge. USFWS would need to provide alternate access.		Little change in access. Refuge facilities protected from future beach erosion.	Paved road access maintained but with some changes.	Access focused on three points; direct access to some Refuge facilities lost.	Access focused on two points; direct access to some Refuge facilities lost.	
Refuge Fishing Access	No fishing catwalks at north end of Hatteras Island. No paved road access to other fishing locations in Refuge.		No fishing catwalks; alternate access possible; beach fishing access unaffected.	No fishing catwalks; alternate access possible; beach fishing access maintained except at southern end.	No fishing catwalks; alternate access possible; beach fishing access limited to 3 locations.	No fishing catwalks; alternate access possible; beach fishing access limited to 2 locations.	
Coastal Conditions Impacts							
Terminal Groin	Not needed for bridge protection.		Retain				
Potential for Breach and Need for Closing Breach to Maintain NC 12	Eliminates breach concerns by bypassing the Refuge. No need to close future breaches.		Nourishment would reduce the risk of a breach. Any breaches through the Refuge would need to be closed.	Breaches in northern portions of the Refuge would need to be closed; a deep breach near the terminal groin could be difficult to fill with sand.	Potential breach areas bridged. No need to close future breaches.	Potential breach areas bridged. Phases II and III may need to be accelerated, if a breach occurred before all four phases are completed.	

Table S-1 (concluded). Comparison of Alternatives

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/ Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge Alternative (Preferred)	Phased Approach/ Rodanthe Nourishment
Natural Resources Impacts							
Biotic Communities Impacts, acres (hectares)							
• Submerged Aquatic Vegetation (SAV)	0.31 (0.13)	0.30 (0.12)	0.20 (0.08)	1.40 (0.56)	1.40 (0.56)	0.20 (0.08)	0.20 (0.08)
• Wetlands	1.84 (0.74)	1.18 (0.48)	1.68 (0.68)	50.74 (20.54)	6.68 (2.71)	0.47 (0.19)	0.44 (0.18)
• Uplands – Natural & Man Dominated	7.97 (3.22)	6.66 (2.70)	20.30 (8.22)	13.45 (5.44)	4.89 (1.98)	13.13 (5.31)	6.45 (2.61)
• Impoundments	0.00 (0.00)	0.00 (0.00)	0.00 (0.00)	22.11 (8.95)	0.43 (0.17)	0.00 (0.00)	0.00 (0.00)
• Aquatic Bottom	2.69 (1.09)	2.70 (1.09)	2.40 (0.97)	3.90 (1.58)	3.82 (1.55)	2.44 (0.99)	2.44 (0.99)
• Total	12.81 (5.18)	10.84 (4.39)	24.58 (9.95)	91.60 (37.07)	17.22 (6.97)	16.24 (6.57)	9.53 (3.86)
Allow for Natural Shoreline Movement	Yes		No	Generally except for groin retention and some dunes.	Yes, except for groin retention.	Yes, once all phases are complete, except for groin retention.	Generally, once all phases are complete, except for groin retention and some nourishment.
Protected Species Adversely Affected							
• Piping Plover	Not likely to adversely affect.		Likely construction/demolition disturbance to nesting; potential nesting, foraging, and roosting habitat lost.				
• Leatherback Sea Turtle/Green Sea Turtle/Loggerhead Sea Turtle	Not likely to adversely affect.		Likely disturbance to nesting on beach; not likely to adversely affect in ocean.				
• Seabeach Amaranth	Not likely to adversely affect.		Beach nourishment could impact habitat.	Not likely to adversely affect.			Beach nourishment could impact habitat.

The Coastal Barrier Resources Act (CBRA) withdraws federal assistance for infrastructure in areas deemed "undeveloped" in 1982. Coastal Barrier Resources System (CBRS) Unit L03 is on Hatteras Island (near Avon and Buxton), but the replacement bridge corridor alternatives (including the Preferred Alternative) are not within an area included in the CBRS. In addition, because the proposed project would consist of the replacement of an existing bridge, as well as an existing road in the case of the Parallel Bridge Corridor, project area development trends would not be altered; therefore, the project would not encourage development in a CBRS area.

The purchase of right-of-way in Rodanthe with any of the alternatives except for those involving nourishment would reduce Dare County's tax base by a fraction of one percent. The replacement of paved road access to the Refuge with an alternative form of access with the Pamlico Sound Bridge Corridor would not likely have a major economic impact on the Outer Banks/Dare County area. Some individual businesses, however, would be more directly affected, and could suffer serious losses.

The formation of a breach in Hatteras Island at the southern end of the Refuge is possible. With the Parallel Bridge Corridor with Nourishment Alternative and the Phased Approach/Rodanthe Nourishment Alternative, a breach in this location would temporarily cut off access (except for limited ferry service) to Hatteras Island to the south of the breach, including both private and public tourism destinations. The economic impact (measured as a reduction in retail sales) of a breach open for three months would be $5.7, $46.3, and $146.7 million in the off-peak, middle, and peak season, respectively. A six month breach covering the middle and peak six months would result in reductions in retail sales of $193.0 million. Jobs and tax revenue would be lost.

The replacement bridge corridor alternatives would not substantially affect community services. Replacing Bonner Bridge with a 17.5-mile (28.2-kilometer) long structure in the Pamlico Sound Bridge Corridor would increase emergency vehicle (ambulances and fire trucks) travel distance to the mainland from Rodanthe and points further south by 2.0 miles (3.2 kilometers) and travel time by approximately two minutes. The time it currently takes emergency vehicles to go this distance would not change with the Parallel Bridge Corridor (including the Preferred Alternative). A new access road to both the Rodanthe-Waves-Salvo Community Center and the emergency ferry dock would be built with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives. With the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative), access would be altered in northern Rodanthe, where two one-way frontage roads would be provided to maintain access to homes and businesses in the area where NC 12 is placed on a bridge. The change would be the greatest with the Phased Approach/Rodanthe Bridge Alternative (Preferred). Utility services would not be lost or interrupted with the replacement bridge corridor alternatives, although the cost of some services could increase in order to cover the cost of moving utility lines. The cost of moving utility lines would be greatest with the Pamlico Sound Bridge Corridor at $53.9 million. These costs would range from $12.1 to $17.4 million with the Parallel Bridge Corridor (including the Preferred Alternative at $17.4 million).

Charter fishing boats operating out of the Oregon Inlet Marina and Fishing Center would no longer be able to use an unmarked natural channel known as "the crack" to reach the ocean, adding approximately 30 minutes to their travel time each way with either corridor alternative.

The Pamlico Sound Bridge Corridor with the Curved Rodanthe Terminus would affect a portion of the Liberty service station, but none of its underground storage tanks (USTs) are within the area directly affected. Both terminus options for the Pamlico Sound Bridge Corridor would affect

the automobile junkyard in the project area. Only one of the Parallel Bridge Corridor alternatives would affect any UST or hazardous waste sites.

The No-Action Alternative would limit the accessibility of Hatteras Island to residents, visitors, workers, and off-island goods and services once the Bonner Bridge reaches the end of its service life and is demolished. This lack of accessibility would adversely affect the economy of the island, as well as the provision of emergency medical services, fire and police protection, schools, solid waste disposal, and utility services.

Environmental Justice

There are no concentrations of any minority group or low-income populations within the project area. Thus, there is no evidence that the replacement bridge corridor alternatives would disproportionately affect low-income or minority households.

Visual

At Rodanthe, panoramic views of the Pamlico Sound from homes along the sound's shoreline would be changed with all alternatives except the Parallel Bridge Corridor with Nourishment Alternative and the two Phased Approach alternatives (including the Preferred Alternative). The location of the Pamlico Sound Bridge Corridor would minimize impacts to views by maintaining a predominantly straight and perpendicular final approach to land. The proposed bridge would not generally obscure the full panorama of the views of Pamlico Sound from homes along the shoreline, but only views to the immediate south or north depending on the location of the homes. For much of the panorama, the proposed bridge would present itself as a thin line on the horizon. The Rodanthe area bridge, included in two of the Parallel Bridge Corridor alternatives, would be closer to the shore over its full length than the Pamlico Sound Bridge Corridor bridge. The intactness and unity of the view would be split by the line of the Rodanthe area bridge across the full 180 degrees of the view.

The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would have a sizable visual effect on Rodanthe, introducing into views an elevated roadway in Rodanthe for a distance of 1.1 miles (1.8 kilometers). The Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative would introduce an elevated roadway in Rodanthe for a distance of 0.3 mile (0.5 kilometer). The elevated roadway also would be introduced into views of the Refuge from Rodanthe. Views of Pamlico Sound from sound-side homes would not be affected.

In the Refuge, the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) and the All Bridge Alternative would represent a sizeable intrusion into the landscape of the Refuge. The bridges would be a sizeable new linear man-made feature for approximately 7.5 to 10 miles (12.1 to 16.1 kilometers) through the Refuge. The visual impact of the other replacement bridge corridor alternatives would be low or nonexistent in the Refuge.

On Bodie Island, a replacement bridge in the Pamlico Sound Bridge Corridor or an Oregon Inlet bridge with any of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be similar in appearance to Bonner Bridge.

With the No-Action Alternative, Bonner Bridge would be removed, so a bridge would no longer be an element of the visual setting of Oregon Inlet.

Cultural Resources

Section 106 of the National Historic Preservation Act of 1966 as amended (16 United States Code [USC] 470f) affords consideration of properties that are listed or eligible for listing on the National Register of Historic Places (NRHP). Section 4(f) of the US Department of Transportation Act of 1966, as amended (49 USC 303), protects publicly owned public parks, publicly owned recreation areas, wildlife and waterfowl refuges, and historic sites of national, state, or local significance from conversion to highway use using FHWA administered funds unless there is no alternative and unless all planning is done to minimize harm. In accordance with the requirements of Section 4(f), Section 106, and the NEPA, surveys were conducted to identify the cultural resources in the project area. There are four resources listed on or eligible for inclusion in the National Register in the project's Area of Potential Effect.

The Pamlico Sound Bridge Corridor would have the following effects on cultural resources:

- No Effect on the National Register-eligible Pea Island National Wildlife Refuge, since the alternative would not be in the Refuge and would not affect the properties that make the Refuge eligible;

- An Adverse Effect on the National Register-listed (former) Oregon Inlet US Coast Guard Station, because of the potential for loss of access (and loss of the ability to move the building to the north across Oregon Inlet), and the potential for removal of the terminal groin at the north end of Hatteras Island upon completion of the proposed project with the foreseeable consequences of erosion (loss of resource); and

- No Adverse Effect on the National Register-listed Chicamacomico Life Saving Station and the associated National Register-eligible Rodanthe Historic District because neither resource would be directly affected. However, the Pamlico Sound Bridge Corridor is within view of these resources.

The Parallel Bridge Corridor alternatives would have the following effects on these historic cultural resources:

- Pea Island National Wildlife Refuge

  - Nourishment Alternative—No Adverse Effect because the new dunes would be on the east side of NC 12 and the existing dikes and ponds would remain.

  - Road North/Bridge South Alternative—Adverse Effect because the relocation of NC 12 would intrude up to 700 feet (213 meters) into the existing dikes and ponds.

  - All Bridge Alternative—Adverse Effect because the elevation of NC 12 on a bridge would place NC 12 over the existing dikes and ponds.

  - The two Phased Approach alternatives (including the Preferred Alternative) —Adverse Effect because of the elevation of the bridge as it passes through the Refuge.

- (Former) Oregon Inlet US Coast Guard Station

  - Nourishment Alternative—Adverse Effect because of the greater height of the new Oregon Inlet Bridge (33.5 to 70 feet [10.2 to 21.3 meters]) compared to the Bonner

Bridge (up to 15 feet [11.1 meters]), which would alter the historic view, function, and setting of the station.

- Road North/Bridge South Alternative—Adverse Effect because of the greater height of the new Oregon Inlet Bridge (33.5 to 70 feet [10.2 to 21.3 meters]) compared to the Bonner Bridge (up to 15 feet [11.1 meters]), as well as a potential new fishing pier, which would alter the historic view, function, and setting of the station.

- All Bridge Alternative—Adverse Effect because of the greater height of the new Oregon Inlet Bridge (33.5 to 70 feet [10.2 to 21.3 meters]) compared to the Bonner Bridge (up to 15 feet [11.1 meters]), as well as a potential new fishing pier, which would alter the historic view, function, and setting of the station.

- The two Phased Approach alternatives (including the Preferred Alternative)—Adverse Effect because of the greater height of the new Oregon Inlet Bridge (33.5 to 70 feet [10.2 to 21.3 meters]) compared to the Bonner Bridge (up to 15 feet [11.1 meters]), as well as a potential new fishing pier, which would alter the historic view, function, and setting of the station.

- The Chicamacomico Life Saving Station and the associated Rodanthe Historic District

  - Nourishment Alternative—No Effect because no component of the alternative would be in proximity to the resource.

  - Road North/Bridge South Alternative—Adverse Effect because the alignment would be within the historic district.

  - All Bridge Alternative—Adverse Effect because the alignment would be within the historic district.

  - Phased Approach/Rodanthe Bridge—Adverse Effect because of the change in the visual setting with a bridge and associated access roads passing through the district. Direct access across NC 12 within the district would be eliminated.

  - Phased Approach/Rodanthe Nourishment—No Effect.

The terms "No Effect", "Adverse Effect", and "No Adverse Effect" refer to the Section 106 process. The concurrence forms for these conclusions are included in Appendix E. No significant archaeological resources would be affected by the project alternatives. A Memorandum of Agreement with the State Historic Preservation Officer related to the Phased Approach/Rodanthe Bridge Alternative (Preferred) is being prepared and will be presented in the Record of Decision.

In addition to the historic resources listed above, the Cape Hatteras National Seashore also is a Section 4(f) resource in the project area. All of the detailed study alternatives would use land from the Seashore. That impact and the conclusion that there is no feasible and prudent alternative to the impact, and that all possible planning has been done to minimize harm is addressed in Chapter 5. The Parallel Bridge Corridor alternatives, except the Phased Approach/Rodanthe Bridge Alternative (Preferred), would use land from the Refuge. The Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives would use land from the Rodanthe Historic District.

Parks and Recreation

The replacement bridge corridor alternatives would be within the Seashore on the Bodie Island side of Oregon Inlet. The Seashore is a Section 4(f) resource. The Pamlico Sound Bridge Corridor would use approximately 7.3 acres (3.0 hectares) of the Seashore on Bodie Island. The Parallel Bridge Corridor (including the Preferred Alternative) would use approximately 6.3 acres (2.6 hectares). The Parallel Bridge Corridor also would be within the Refuge (in an area held in common with the Seashore) on Hatteras Island. The Refuge is also a Section 4(f) resource. The Parallel Bridge Corridor alternatives would use land from the Refuge as follows:

- Nourishment. 19.7 acres (8.0 hectares) associated with new dunes plus nourishment of 6.3 miles (10.1 kilometers) of the seashore within the Refuge. NC 12 would remain in its current easement. A new access road to the Oregon Inlet area parking lot would involve 0.2 acre (0.07 hectare) of new easement.

- Road North/Bridge South. 90.3 acres (36.6 hectares) of new 100-foot (30.5-meter) wide new easement would be used for the relocated NC 12 as a roadway and bridge. Approximately 2,961 feet (903 meters) of new bridge would be built over Refuge lands. A new access road to the Oregon Inlet area parking lot would involve 0.2 acre (0.07 hectare) of new easement. Ultimately, 2.9 acres (1.2 hectares) of area would be used by three new dunes, with the earliest built in 2030, assuming forecast high erosion trends.

- All Bridge. 89.6 acres (36.2 hectares) of new 100-foot (30.5-meter) wide easement would be used for the relocated NC 12 as a roadway and bridge. Approximately 7.6 miles (12.2 kilometers) of new bridge would be built over Refuge lands. A new access road to the Oregon Inlet area parking lot would involve 2.6 acres (1.1 hectares) of new easement.

- Phased Approach alternatives (including the Preferred Alternative). The total area of disturbance within the existing easement in the Refuge would be 3.7 acres (1.5 hectares) permanent and 48.5 acres (19.6 hectares) temporary. No new easement would be used in the Refuge, but with the Phased Approach/Rodanthe Nourishment Alternative, nourishment would occur on 1,500 feet (457.2 meters) of seashore within the Refuge.

With either the Pamlico Sound Bridge or Parallel Bridge corridors (including the Preferred Alternative), charter fishing boats operating out of the Seashore's Oregon Inlet Marina and Fishing Center no longer would be able to use the channel known as "the crack," adding about 30 minutes to their trip from the fishing center to the ocean.

With all alternatives, construction activities may require either dredging, a haul road, and/or work bridge within the portions of the Seashore in Pamlico Sound.

With the Pamlico Sound Bridge Corridor, NC 12 between Bodie Island and Hatteras Island no longer would pass through the Seashore and Refuge. Paved road access would continue in the Refuge with the Parallel Bridge Corridor. Access would focus on three points in the Refuge with the All Bridge Alternative and two points with the Phased Approach alternatives (including the Preferred Alternative). Access would be lost to the Refuge Visitor Center, headquarters, and North Pond Trail with the All Bridge and Phased Approach alternatives (including the Preferred Alternative).

The fishing catwalks on Bonner Bridge probably would not be placed on a new bridge with its assumed greater height and span lengths. For the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor with Road North/Bridge South, All Bridge, and Nourishment alternatives, options

for retaining fishing opportunities offered by the catwalks include maintaining a part of Bonner Bridge as a fishing pier, or building a "boardwalk" on top of the riprap that currently blankets the northern shore of Hatteras Island. When Phase I of the Phased Approach alternatives (including the Preferred Alternative) – the new Oregon Inlet bridge – is complete, the temporary traffic maintenance bridge could be left in place as a fishing pier, replacing the catwalks. This also could occur with the Nourishment Alternative. The use of a traffic maintenance bridge is one option that could be considered for maintaining traffic at the south end of the new bridge where it is being constructed in the existing bridge easement. A traffic maintenance bridge is not needed with the other replacement bridge corridor alternatives, so leaving one in place is not an option with the other alternatives. Some government body or non-governmental organization would have to take responsibility for the operation, maintenance, and liability of any new fishing pier.

Unlike the other Parallel Bridge Corridor alternatives, the Phased Approach alternatives (including the Preferred Alternative) would directly affect activities on the beach front, including fishing, hiking, surfing, wind surfing, kite boarding, swimming, ocean kayaking, and birding. Bridge piles in the ocean could change the types of fish that congregate around the shore. To the extent that certain sections of the bridged roadway would be over the beach, beach activities would be affected, but not precluded, by the presence of the bridge and bridge piles. Once the Phased Approach alternatives' bridge piles are in the ocean, the ability to surf in a particular area would be eliminated. The piles would change how and where the waves break, which would interfere with the swells in such a way that the waves would no longer be conducive to good surfing. In addition, the presence of bridge piles every 120 feet (36.6 meters), in areas where the bridges would be less than 150 feet (45.7 meters) from shore, would be a safety hazard to surfers and other recreational ocean users.

For recreational users of the Pamlico Sound, the Pamlico Sound Bridge Corridor would place an obstruction in the sound as the bridge moves from the shoreline at Rodanthe to a point approximately 5 miles (8 kilometers) west of Hatteras Island. The ability of recreational users to pass from one side of the bridge approach to the other would be limited by its 140 to 150 feet (42.7 to 45.7 meters) span length between piers and a vertical clearance of approximately 10 feet (3.1 meters) above mean high water (outside the navigation zone). A similar obstruction in Pamlico Sound would be placed immediately off-shore of Rodanthe with the Parallel Bridge Corridor with the Road North/Bridge South and All Bridge alternatives.

The No-Action Alternative, and the associated demolition and removal of Bonner Bridge, would also result in the demolition of the fishing catwalks on the bridge. No other parks or recreation resources would be affected, although access to recreation facilities within the Refuge would be limited.

Coastal Conditions

A bridge within the replacement bridge corridor alternatives would have a negligible effect on inlet migration, profile, and gorge alignment other than the continued effect of the presence of the terminal groin with the Parallel Bridge Corridor alternatives (including the Preferred Alternative). Flood levels under storm surge conditions would not increase with a replacement bridge in the Pamlico Sound Bridge or Parallel Bridge corridors. The performance of the terminal groin would not be affected by the construction of a bridge in the replacement bridge corridors. The groin would need to be retained with the Parallel Bridge Corridor's bridge over Oregon Inlet. The new Oregon Inlet crossing with either corridor would make navigation channel dredging operations easier to undertake and could reduce the frequency and size of dredging operations from what is required today.

An ongoing Coastal Cooperative Research Program study found that there are five potential breach locations within the Refuge. The word "breach" is used rather than the word "inlet" because if a breach were to occur as the result of a storm, it would likely close eventually (although not necessarily immediately) and likely would not be a long-term phenomenon like Oregon Inlet. The one possible exception to this likelihood is the potential breach location at the southern end of the Refuge near Rodanthe. However, it would be of concern only with the Parallel Bridge Corridor with Nourishment Alternative if this potential breach were to remain open. Based on the 2003 experience at the Hatteras Village breach on Hatteras Island and the opinions of a panel of coastal experts, closure of a breach would take three months (with advanced planning) to six months and cost an estimated $7 to $11 million. The potential also exists for a deep breach near the terminal groin, resulting in part from soundside erosion. It would likely need to be closed with a bridge, such as the type included in the two Phased Approach alternatives (including the Preferred Alternative) and the All Bridge Alternative.

With the two Phased Approach alternatives (including the Preferred Alternative), the shoreline will naturally erode under the associated bridges. By 2060, because of this erosion most of the NC 12 bridges associated with these alternatives would be in the ocean rather than on the shore. When exposed to waves, tides, and storm events, the presence of bridge piles would alter the flow pattern around the piles, resulting in scour, effects on cross-shore transport during storm events, formation of additional rip currents, and changes in beach erosion and accretion patterns. Since the Phased Approach alternatives (including the Preferred Alternative) would be built in phases, storm-related NC 12 maintenance of the existing roadway within the 100-foot easement would continue in the three hot spots and likely increase in those areas until Phase II is completed. NCDOT intends to place a high priority on the implementation of Phase II as soon as it is practicable. The completion of Phase II would substantially decrease the amount of storm-related maintenance on the NC 12 roadway, but some would remain.

NCDOT also would not perform storm-related NC 12 maintenance work outside the existing easement in the Phase III, IV, and no action areas on NC 12 for the reason noted in the previous paragraph. Limiting the growth in the need for NC 12 storm-related maintenance in the Phase III and IV areas to the extent practicable given the availability of transportation funding and the efficient use of those funds also is considered desirable. In order to help accomplish that objective, NCDOT would implement a monitoring program, the particulars of which would be developed in consultation with representatives of the Refuge, including development of decision-making criteria for translating monitoring findings into a decision to move forward with an additional phase and how to refine the location of each phase to reflect actual future shoreline change.

Natural Systems

The Pamlico Sound Bridge Corridor and, to a greater extent, the Parallel Bridge Corridor would result in localized, construction-related changes in topography and soils, especially in low-lying areas. Temporary water quality impacts would result from construction barge traffic, fill and pile placement, and construction channel dredging. These activities would cause a temporary increase in turbidity and a potential decrease in dissolved oxygen levels associated with the re-suspension of sediment particles into the water column. Long-term impacts to water quality include runoff that may contribute pollution to nearby ecosystems. Highway runoff can contain varying amounts of heavy metals, nutrients, organic compounds, and particulates, all of which can degrade water quality and impact aquatic organisms. Bridge Stormwater Controls presented in NCDOT's *Stormwater Best Management Practices Toolbox* (NCDOT, 2008), or proprietary devices applicable to controlling bridge deck runoff, would be considered for all bridge replacement segments traversing the receiving water bodies.

A bridge in the Pamlico Sound Bridge Corridor would permanently affect 10.8 to 12.8 acres (4.4 to 5.2 hectares) of biotic communities. Approximately half of this impact would be to man-dominated uplands. Section 404 (Clean Water Act) jurisdictional areas would comprise up to 4.8 acres (2.0 hectares), including 1.8 acres (0.7 hectare) of wetland and 3.0 acres (1.2 hectares) of open water in the affected area. The wetland loss would include less than 0.01 acre (0.01 hectare) of CAMA coastal wetlands with the Pamlico Sound Bridge Corridor alternatives. CAMA coastal wetlands are environmentally fragile and important land and water areas that are judged to be of greater than local significance according to the pertinent coastal county local land use plan. A permit is required from the NCDENR's Division of Coastal Management (DCM) for development activities that take place in CAMA coastal wetlands.

The Parallel Bridge Corridor with the Road North/Bridge South Alternative would fill the largest area of biotic communities at 91.6 acres (37.1 hectares), whereas the Phased Approach/Rodanthe Bridge Alternative (Preferred) would fill 16.2 acres (6.6 hectares), the Phased Approach/ Rodanthe Nourishment Alternative would fill 9.5 acres (3.9 hectares), the All Bridge Alternative would fill 17.2 acres (7.0 hectares), and the Nourishment Alternative would fill 24.6 acres (10.0 hectares). The Pamlico Sound Bridge Corridor alternatives would fill approximately 10.8 to 12.8 acres (4.4 to 5.2 hectares). Therefore, all of the alternatives, except the Parallel Bridge Corridor with Road North/Bridge South Alternative, would be of a similar order of magnitude in terms of permanent fill impacts, with a maximum difference between these alternatives of approximately 15.1 acres (6.1 hectares). The two Phased Approach alternatives (including the Preferred Alternative) also would have 48.5 acres (19.6 hectares) of temporary biotic community impact associated with temporary traffic maintenance roads.

With the Phased Approach alternatives (including the Preferred Alternative), the habitat affected by the completed bridges would change from what is described above over time as the shoreline erodes under the bridges. The maximum length of bridge over the ocean would be 8 miles (12.9 kilometers) in 2060. The maximum length of bridge over beach habitat would be 3.3 miles (5.3 kilometers) in 2020.

Section 404 jurisdictional impacts also would be greatest with the Road North/Bridge South Alternative at 78.2 acres (31.6 hectares), including 50.7 acres (20.5 hectares) of wetland and 27.4 acres (11.1 hectares) of open water. The jurisdictional impact of the other six alternatives would be at a comparable order-of-magnitude, with the All Bridge Alternative being the greatest (12.3 acres [5.0 hectares]) of the other six alternatives and the Phased Approach alternatives (including the Preferred Alternative) comprising the least (3.1 acres [1.3 hectares]).

Fill of CAMA coastal wetlands would be the greatest with the Road North/Bridge South Alternative at approximately 11.8 acres (4.8 hectares). The All Bridge Alternative would fill approximately 2.2 acres (0.9 hectare) of CAMA coastal wetlands, while the Nourishment Alternative would fill approximately 0.3 acre (0.1 hectare), and the two Phased Approach alternatives (including the Preferred Alternative) would fill 0.3 acre (0.1 hectare). The two Phased Approach alternatives (including the Preferred Alternative) also would have 12.5 acres (5.0 hectares) of temporary wetland impact, including 3.1 acres (1.3 hectares) of CAMA wetland impact. The other three Parallel Bridge Corridor alternatives would have 6.0 acres (2.4 hectares) of temporary wetland impact, including 1.1 acres (0.4 hectare) of CAMA wetland impact. Efforts were made to avoid and minimize wetland impacts in developing each of the alternatives. Opportunities for compensatory mitigation exist.

Pamlico Sound dredging would likely be needed for approximately 8.0 miles (12.8 kilometers) of the 17.5-mile (28.2-kilometer) length of the Pamlico Sound bridge. With the Parallel Bridge

Corridor, dredging would likely be needed just north of Hatteras Island for approximately 2,000 feet (610 meters) to build the Oregon Inlet bridge. No dredging is anticipated in areas where submerged aquatic vegetation (SAV) is present. On the Bodie Island side of Oregon Inlet, Parallel Bridge Corridor bridge construction would likely involve construction of a temporary haul road for approximately 2,400 feet (732 meters) immediately west of the new Oregon Inlet bridge. It would temporarily affect 6.5 acres (2.6 hectares) of biotic communities.

Temporary wetland impacts would occur with demolition and removal of Bonner Bridge. The extent of the impact would depend on the access technique used. NCDOT would coordinate with environmental resource and regulatory agencies prior to bridge demolition and removal to determine the most practicable construction access methodology for the demolition of Bonner Bridge.

The Pamlico Sound Bridge Corridor would not result in permanent disturbance to Significant Natural Heritage Areas (SNHA) identified by the North Carolina Natural Heritage Program (NCNHP). Construction of this bridge would disturb fish and shellfish resources in areas affected by pile placement and const biotic communities, as well ruction channel dredging. The Pamlico Sound Bridge Corridor would cross the northern end of Crab Slough, an area of high shellfish density. The construction of the Parallel Bridge Corridor would result in permanent and temporary disturbance to the Refuge, identified as a SNHA by the NCNHP, with all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative). Construction of these alternatives would disturb wetland as fish and shellfish resources, in areas affected by pile placement, construction channel dredging, and fill. The Parallel Bridge Corridor would cross Oregon Inlet just east of both Oregon Inlet Shoal and the rising shoals just north of Hatteras Island, important bird foraging habitat area.

Both replacement bridge corridor alternatives would produce turbidity, noise, and siltation resulting from construction, which in turn would create localized, short-term impacts to essential fish habitat (EFH) including estuarine emergent wetlands, oyster reef and shell bank, SAV beds, intertidal flats, and marine and estuarine water column. Although some small adverse impacts to EFH would occur during construction, the impacts would be temporary and are not expected to result in significant short-term or long-term adverse effects on managed species. Direct dredging-related impacts on marine EFH would result from noise and turbidity, sediment removal, and burial of organisms by fine sediments falling back to the sea floor. The result would be short-term adverse effects on biota and managed species that use benthic habitats, but long-term and permanent impacts to EFH and managed species are expected to be minimal. The extent of benthic community impacts are discussed below. If changes to benthic invertebrate communities do result, this does not necessarily mean EFH would be degraded or that negative impacts to managed species would result because most benthic communities are resilient and likely to recover quickly. Permanent loss or alteration of estuarine emergent habitat, seagrass, oyster reef and shell bank, and intertidal flats would result directly from shading and pile placement. Bridge and pile placement could result in several indirect impacts, including changes to: water flow; sediment grain size and topography; and light levels of the area underneath the bridge and for some distance surrounding the bridge. The changes described here are expected to have a minimal adverse effect on EFH and managed species.

Benthic communities would be affected primarily by fill impacts in open water (including SAV) and marsh communities (smooth cordgrass, black needlerush, salt flats, and brackish marsh). Both Pamlico Sound Bridge Corridor alternatives would result in pile fill of 2.7 acres (1.1 hectares) of open water and 0.3 acre (0.1 hectare) of SAV. Fill impacts to open water and marsh communities with the Parallel Bridge Corridor alternatives would be the greatest with the Road North/Bridge South Alternative at approximately 39.2 acres (15.8 hectares), whereas the All

Bridge Alternative would fill 7.9 acres (3.2 hectares), the Phased Approach alternatives (including the Preferred Alternative) would fill 3.0 acres (1.2 hectares), and the Nourishment Alternative would fill 2.9 acres (1.2 hectares).

In general none of the alternatives would cause changes to commercial fishing when compared to existing conditions. The two Phased Approach alternatives (including the Preferred Alternative) could result in some effect to inshore commercial fishing.

Wildlife and bird disturbances would be minimized with the Pamlico Sound Bridge Corridor since it would remove NC 12 from the Refuge. The Parallel Bridge Corridor alternatives (including the Preferred Alternative) would continue disturbances associated with road kill, noise, and habitat loss during construction and road operation. Disturbances associated with storm-related maintenance would continue with the Phased Approach alternatives (including the Preferred Alternative) until all phases are complete. The greatest period of these disturbances would be prior to the completion of Phase II.

The Pamlico Sound Bridge Corridor would allow the most natural shoreline movement to occur. This natural cyclic process, which includes allowing dunes to erode, storms to overwash the island, and washover deposits to remain in place, is thought to benefit the barrier island system by helping to maintain the natural ecological character and allowing the formation of ephemeral habitats (e.g., overwash fans, new inlets, and low sloping beaches that serve as habitat for avian species). The Parallel Bridge Corridor alternatives (including the Preferred Alternative), except for the Nourishment Alternative, also generally would allow long-term natural shoreline movement except for the retention of the terminal groin. Also, it is estimated that the Phased Approach alternatives (including the Preferred Alternative) would not be completed until at least 2030. Until all phases are complete, NC 12 maintenance in the incomplete sections could affect natural shoreline movement.

The Pamlico Sound Bridge Corridor would not likely result in adverse impacts to the 13 federally-listed threatened or endangered species in Dare County. With the Pamlico Sound Bridge Corridor, the biological conclusion for 10 of these species is "May Affect – Not Likely to Adversely Affect," and the biological conclusion for three species is "No Effect." With the Parallel Bridge Corridor, the biological conclusion for six of these species (five species with the Nourishment and Phased Approach/Rodanthe Nourishment alternatives) is "May Affect – Not Likely to Adversely Affect," the biological conclusion for three species is "No Effect," and the biological conclusion for four species (five species with the Nourishment and Phased Approach/ Rodanthe Nourishment alternatives) is "May Affect – Likely to Adversely Affect." The bald eagle, which was recently delisted, is not included as one of the 13 species listed above. The biological conclusion for the bald eagle, however, is "May Affect – Not Likely to Adversely Affect" for both the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor. Formal consultation was completed for the Phased Approach/Rodanthe Bridge Alternative (Preferred). Concurrence was obtained on biological conclusions from both the USFWS and National Marine Fisheries Service (NMFS). USFWS identified several conservation measures and reasonable and prudent measures to be implemented in association with the Phased Approach/Rodanthe Bridge Alternative (Preferred) by FHWA and NCDOT to minimize impacts to protected species. The NMFS asked that NCDOT comply with their March 23, 2006, *Sea Turtle and Smalltooth Sawfish Construction Conditions* (NMFS, 2006). FHWA and NCDOT will implement the measures requested by USFWS and NMFS.

With the No-Action Alternative, a small-scale ferry system would be instituted in the place of new bridge construction. Unlike the replacement bridge corridor alternatives, which would create

primarily temporary construction impacts, the No-Action Alternative would create long-term adverse impacts to natural systems in the project area. The ferry system would necessitate extensive dredging to maintain its navigation channels across Oregon Inlet, potentially resulting in long-term disturbance to SAV beds, wetlands, and benthic communities. Also, wetland fill would be necessary if construction of a new ferry docking area were required.

Air Quality

A microscale air quality analysis was conducted to determine the potential effects of the replacement bridge corridor alternatives (including the Preferred Alternative) on local air quality. The "worst-case" project-level carbon monoxide (CO) concentrations were determined for the existing year (2002) and design year (2025). These CO concentrations were then compared to the National Ambient Air Quality Standards (NAAQS). The maximum one-hour and eight-hour CO levels predicted were below NAAQS maximum levels. Thus, the proposed project would not cause or exacerbate a violation of the NAAQS. The project is in Dare County, which has been determined to comply with National Ambient Air Quality Standards. The proposed project is in an attainment area; therefore, Title 40 *Code of Federal Regulations* Parts 51 and 93 are not applicable. This project is not anticipated to create any adverse effects on the air quality of this attainment area.

The No-Action Alternative assumes that Bonner Bridge is demolished at the end of its service life and not replaced. This likely would result in a dramatic but unknown decrease in traffic on NC 12, since limited ferry capacity would discourage both visitors to Hatteras Island, as well as future growth in the permanent population. Thus, No-Action Alternative CO levels could not be modeled for comparison with the replacement bridge corridor alternatives, as is customary for this type of analysis. CO levels were, however, modeled assuming 2025 traffic on NC 12 if Bonner Bridge were to remain in place.

Increases in the emission of Mobile Source Air Toxics (MSATs) are not expected with the replacement bridge corridor alternatives or the No-Action Alternative.

Noise

The noise level and abatement analysis for the replacement bridge corridor alternatives indicates that FHWA's Noise Abatement Criteria (NAC) would be approached or exceeded at three or four residences, depending on the Pamlico Sound Bridge Corridor Rodanthe terminus option implemented. In addition, a substantial increase in noise levels would occur at two residences with either Pamlico Sound Bridge Corridor terminus option. The NAC would be approached or exceeded at four residences with the Parallel Bridge Corridor with Nourishment Alternative, as well as with the Phased Approach/Rodanthe Nourishment Alternative. The NAC would be approached or exceeded at two residences with the other Parallel Bridge Corridor alternatives (including the Preferred Alternative). No reasonable or feasible opportunities exist to reduce noise levels at any of these residences.

The No-Action Alternative assumes that Bonner Bridge is demolished at the end of its service life and not replaced. This likely would result in a dramatic but unknown decrease in traffic on NC 12, since limited ferry capacity would discourage both visitors to Hatteras Island, as well as future growth in the permanent population. Thus, the No-Action Alternative noise levels could not be modeled for comparison with the replacement bridge corridor alternatives, as is customary for this type of analysis. Noise levels were, however, modeled assuming 2025 traffic on NC 12 if the Bonner Bridge were to remain in place.

Energy

The energy used in construction of any of the replacement bridge corridor alternatives would be greater than that required to build the small ferry service associated with the No-Action Alternative. This benefit, however, would be offset, at least in part, by the higher maintenance and operation energy use of the No-Action Alternative. A substantial difference in motor vehicle energy use would not be expected between the replacement bridge corridor alternatives and the No-Action Alternative.

Differences in energy use related to the construction and maintenance of the replacement bridge corridor alternatives are directly reflected in differences in their cost. The higher the cost, the more energy is expended. The relative energy use of the replacement bridge corridor alternatives based on their cost from greatest to least use would be:

1. Either Pamlico Sound Bridge Corridor Alternative (2.2 to 2.4 times the energy use of the least use alternative);

2. Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative (1.9 to 2.0 times the energy use of the least use alternative);

3. Parallel Bridge Corridor with All Bridge Alternative (1.8 to 2.0 times the energy use of the least use alternative);

4. Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) (1.8 to 1.9 times the energy use of the least use alternative);

5. Parallel Bridge Corridor with Nourishment Alternative (1.1 to 1.3 times the energy use of the least use alternative); and

6. Parallel Bridge Corridor with Road North/Bridge South Alternative (the least energy use alternative).

All alternatives would require demolition and removal of Bonner Bridge, but the energy use by equipment would be similar for all alternatives.

Indirect and Cumulative Impacts

Because the proposed project would consist of the replacement of an existing bridge, as well as an existing road in the case of the Parallel Bridge Corridor, indirect impacts would be minimal. The replacement bridge corridor alternatives would not alter area development trends.

From the perspective of cumulative impacts, the Pamlico Sound Bridge Corridor would support the desire of officials responsible for the Refuge and the Seashore to not stabilize the Outer Banks artificially, but rather to let natural processes take their course. The Parallel Bridge Corridor with All Bridge Alternative, as well as the two Phased Approach alternatives (including the Preferred Alternative), would support this desire, with the exceptions of the continued presence of the terminal groin and some nourishment associated with the Phased Approach/Rodanthe Nourishment Alternative. The Parallel Bridge Corridor with Road North/Bridge South Alternative also would generally support this desire. Exceptions would be the continued presence of the terminal groin, the eventual construction of three dunes, and any breach closure that may be needed to maintain the transportation corridor within the Refuge. The Parallel Bridge Corridor

with Nourishment Alternative would not support this desire since it would maintain NC 12 by stabilizing the shoreline with nourishment and protecting NC 12 with dunes.

The Pamlico Sound Bridge Corridor, given that it would bypass the Refuge, could affect future decision-making related to:

- NC 12 maintenance in the Refuge;
- Access within the Seashore north of Rodanthe and the Refuge;
- Oregon Inlet dredging and associated impacts to the bottom of Pamlico Sound;
- The preservation and re-use of the (former) Oregon Inlet US Coast Guard Station at the north end of Hatteras Island; and
- The disposition of the terminal groin at the north end of Hatteras Island.

The specific direction these future decisions might take is not foreseeable. In all cases, however, appropriate planning and environmental studies would be conducted before any final decisions are made. The NCDOT will participate in those studies.

The Parallel Bridge Corridor (including the Preferred Alternative), which leaves NC 12 within the Refuge, would influence future dredging decisions from two perspectives.

1. The longer navigation zone of the Oregon Inlet bridge would allow the dredged channel to move with the natural gorge.
2. Some dredging spoils could be used as a part of the Nourishment Alternative.

The terminal groin must be retained with all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative). The retention of the groin would allow the (former) Oregon Inlet US Coast Guard Station to remain in its current location with access to NC 12, if desired by its owners.

All alternatives would affect future decisions related to the relocation of electrical and telephone utilities in response to shoreline erosion, as well as the associated impacts of such relocations to upland habitat and wetlands. It also is reasonably foreseeable that telephone and electrical lines along NC 12 would need to be moved one or more times between now and the design year of this analysis, 2060.

The Pamlico Sound Bridge Corridor alternatives would offer both the removal of NC 12 from the Refuge and removal of the disturbances to Refuge wildlife, including those disturbances from NC 12 storm maintenance and traffic operations. The Refuge contains almost all of the remaining undisturbed (i.e., not used for driving, or adjoining development or potential development) beach on the Outer Banks. The Nourishment Alternative and the Phased Approach alternatives (including the Preferred Alternative) would result in the greatest disturbance to that scarce resource. Beach erosion would result in portions of the Phased Approach alternatives (including the Preferred Alternative) eventually being over the beach and in the ocean. The presence of the bridge in this location would adversely impact the shoreline from the perspective of its natural appearance, recreational use, the outcome of coastal processes along the beach, and wildlife, including protected species that use beach habitat.

Construction

Construction of the proposed project in either replacement bridge corridor, as well as the demolition and removal of Bonner Bridge, would be governed by the NCDOT's *Standard Specifications for Roads and Structures* (NCDOT, July 2006, or as current at the time of construction), and the American Association of State Highway and Transportation Officials' (AASHTO) *Standard Specifications for Highway Bridges* (AASHTO, 2002, or as current at the time of construction).

Mechanisms would be put in place to maintain traffic flow; minimize air quality, noise, and construction lighting impacts; manage waste disposal; minimize construction access impacts; protect surrounding natural resources; control erosion; and handle any accidental waste spills. Affected geodetic survey markers in the project area would be properly relocated.

Costs

Costs through 2060 associated with the detailed study alternatives are shown in Table S-2. These costs include construction, operation and maintenance, right-of-way, Bonner Bridge demolition, and wetland mitigation (except SAV) costs. The alternatives that involve longer bridge components to the south of the Oregon Inlet area, including the Phased Approach/Rodanthe Bridge Alternative (Preferred), would be the most expensive.

Table S-2. Project Costs

Alternative	Total Highway Costs through 2060	
Pamlico Sound Bridge Corridor	**Low**	**High**
• Curved Rodanthe Terminus	$1,305,564,000	$1,797,564,000
• Intersection Rodanthe Terminus	$1,299,066,000	$1,788,066,000
Parallel Bridge Corridor		
• Nourishment	$671,835,000	$970,350,000
• Road North/Bridge South	$602,208,000	$740,208,000
• All Bridge	$1,107,683,000	$1,435,283,000
• Phased Approach/Rodanthe Bridge Alternative (Preferred)	$1,171,459,000	$1,497,113,000
• Phased Approach/Rodanthe Nourishment	$1,149,098,000	$1,524,350,000

S.7 Areas of Controversy

Environmental resource and regulatory agencies included on the NEPA/Section 404 Merger Team have indicated a strong preference for the Pamlico Sound Bridge Corridor because of its lower potential natural resource impacts. However, this alternative is not financially viable, in that adequate resources are not available to fund the initial bridge construction. The Phased Approach/Rodanthe Bridge Alternative (Preferred) is financially viable in that it can be built in

phases, spreading the cost out over a timeframe adequate for it to be funded with anticipated future tax revenues. It also would remain in the existing NC 12 easement within the Pea Island National Wildlife Refuge and, therefore, would not use lands from the Refuge.

S.8 Major Unresolved Issues with Other Agencies

The Assistant Secretary for Fish and Wildlife and Parks of the US Department of the Interior indicated (in a September 11, 2007 letter) that, based on the information that the USFWS had as of that date, it was unlikely that they could find the Preferred Alternative to be compatible with the purposes for which the Refuge was established, as required under the 1997 National Wildlife Refuge System Improvement Act, because the potential exists for NC 12 continued maintenance outside the existing NC 12 easement. However, NCDOT would not perform storm-related NC 12 maintenance work outside the existing easement. Because the Preferred Alternative would be confined to the existing NC 12 easement, FHWA and NCDOT have concluded that a determination of compatibility is not required.

S.9 Other Federal Actions Required for the Preferred Alternative

The following permits would be required from federal agencies for implementation of the Phased Approach/Rodanthe Bridge Alternative (Preferred):

- US Coast Guard Bridge Permit for the Oregon Inlet bridge (Phase I) component of the Preferred Alternative. An additional bridge permit might be needed when the shoreline erodes under the Preferred Alternative's bridges, thereby placing them in the ocean;
- US Army Corps of Engineers Sections 404 and 10 permits (waters of the United States fill and dredge permits) and perhaps a Section 103 Permit (ocean disposal of dredged material);
- National Park Service Special Use Permit; and
- New US Fish and Wildlife Service permit for the terminal groin and revetment (the existing permit states that the groin's intended use is only to protect the current Bonner Bridge).

These same permits would be required for the other Parallel Bridge Corridor alternatives; however, the following additional permits also would be required, as applicable, from the USFWS:

- Right-of-Way Permit (when leaving the current easement in the Refuge) and
- Special Use Permit (for temporary impacts because of construction, temporary detours, and beach nourishment within the Refuge).

The Pamlico Sound Bridge Corridor alternatives also would require a US Coast Guard Bridge Permit, US Army Corps of Engineers Sections 404 and 10 permits (and perhaps a Section 103 Permit), and a National Park Service Special Use Permit. However, no USFWS permits would be required with the Pamlico Sound Bridge Corridor alternatives.

No other federal actions would be required with any of the replacement bridge corridor alternatives (including the Preferred Alternative).

S.10 North Carolina Legislation Related to Bonner Bridge Replacement

During its 2005 Session, the North Carolina General Assembly passed legislation (House Bill 747) related to the replacement of Bonner Bridge. The bill calls for expediting and accelerating the efficient, cost-effective completion of the project; indicates a preference for a bridge replacement in proximity to Bonner Bridge; and requests the NCDOT to periodically report project status to the General Assembly.

NC 12 Replacement of the Herbert C. Bonner Bridge

(Bridge No. 11) over Oregon Inlet

Federal-Aid No. BRS-2358(15)
State Project No. 8.1051205
TIP Project No. B-2500
Dare County, North Carolina

Project Commitments

Highway Design Branch

1. Navigation Span Location. One navigation zone would be built to serve boats passing through Oregon Inlet. The location of the zone would be determined in coordination with the US Army Corps of Engineers (USACE).

2. Bicycle Accommodations. The Seashore management plan supports the use of bicycles along NC 12. All bridges in both replacement bridge corridors (including the Preferred Alternative) would have 8-foot (2.4-meter) wide shoulders that would be safer for bicycle and pedestrian traffic than Bonner Bridge's 2-foot (0.6-meter) wide shoulders. In addition, a bicycle-safe bridge rail on the bridges also would provide increased safety for bicyclists. New roadway would have 4-foot (1.2-meter) paved shoulders, which would be safer for use by bicycle and pedestrian traffic than existing NC 12's unpaved shoulders.

Highway Design Branch and Division 1

3. Use of Work Bridges. During construction in the Pamlico Sound Bridge Corridor, steps taken to minimize turbidity (when possible and practicable) would include the use of work bridges (rather than dredging for barges) for movement of construction equipment in shallow areas where submerged aquatic vegetation (SAV) is present. If SAV is in waters deep enough to float a barge without dredging, the use of a work bridge would not be necessary. Work bridges also would be used to carry construction equipment over intertidal marsh areas (black needlerush and smooth cordgrass). Dredging generally would only be used in depths less than 6 feet (1.8 meters) where SAV is not present. In the Parallel Bridge Corridor (including the Preferred Alternative), work bridges would be used for building proposed bridges over wetlands south of Oregon Inlet.

   The Oregon Inlet bridge would generally be built from a barge. West of Bodie Island, a temporary haul road on geotextile fabric, dredging, or a work bridge could be used. Use of a work bridge instead of a haul road for short distances at critical locations, such as SAV locations, would be considered prior to construction.

4. Sedimentation and Erosion Control. All waters in the project area are classified as SA waters (Class A salt waters) with a supplemental classification of High Quality Waters (HQW). The most stringent application of the Best Management Practices (BMPs) is expected where highway projects affect receiving waters of special designation, such as HQW. Also, impacts to adjacent areas of SAV and/or wetlands should be minimized. Therefore, sedimentation

and erosion control measures shall adhere to the Design Standards in Sensitive Watersheds [15A NCAC 04B.0124(b)-(e)]. Prior to construction, the design-build contractor will submit the proposed sediment and erosion control plans for each stage of construction to the NCDOT and permitting agencies for review.

5. Pile Placement. Bridge piles in open water would be jetted to the tip elevation (depth of the tip of the pile). Bridge piles over land would be jetted or driven.

6. Use of Bridge Demolition Debris for an Artificial Reef. The NCDOT would work with the NC Division of Marine Fisheries to accommodate this desire during demolition planning. Coordination also would be conducted with the National Marine Fisheries Service (NMFS) in association with their regulation of several protected species.

Highway Design Branch, Project Development and Environmental Analysis Branch, and Division 1

7. Design Coordination. The NCDOT would invite the National Park Service (NPS) and the US Fish and Wildlife Service (USFWS) (in the case of the Parallel Bridge Corridor alternatives including the Preferred Alternative) to participate in the development of project design and mitigation strategies as a part of the permit application process.

8. Dredging. To avoid construction impacts to protected turtles, the NCDOT's contractor would use pipeline or clamshell dredging. A hopper dredge would not be used for bridge construction or Bonner Bridge demolition.

9. Disposal of Dredged Material. Prior to construction, during the USACE permit preparation process, the FHWA and the NCDOT would work with appropriate environmental resource and regulatory agencies to identify the characteristics of dredged material from bridge construction in open water and develop a disposal plan that would minimize harm to natural resources. The appropriate location for dredged material disposal would be determined based on the character of the materials dredged, the availability of disposal sites, and coastal conditions near the time of construction. In addition, the terms and conditions outlined in the *Biological and Conference Opinion*s (USFWS, 2008) related to piping plovers specify that "all dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission."

10. Night-time Construction. Because construction activities could occur 24-hours-a-day, construction areas could be lit to daylight conditions at night. The NCDOT would work with the North Carolina Department of Environment and Natural Resources' Division of Marine Fisheries, the National Marine Fisheries Service, the NPS, and the USFWS to determine other areas near project construction where night lighting would need to be avoided or limited. Night lighting also would not be used close to areas where people sleep, including the campground at the northern end of the project area and the Rodanthe area at the southern end. Night lighting also will meet the requirements specified to protect sea turtles contained within Commitment 25a.

11. Manatee Protection. Construction contracts would require compliance with the USFWS' Guidelines for Avoiding Impacts to the West Indian Manatee: Precautionary Measures for Construction Activities in North Carolina Waters (June 2003).

12. Sea Turtle and Smalltooth Sawfish Protection. NCDOT will comply with the NMFS's March 23, 2006, *Sea Turtle and Smalltooth Sawfish Construction Conditions* (NMFS, 2006) that restrict in-water construction-related activities when these protected species are observed in the project area. However, the NMFS and NCDOT agree that bridge construction or demolition activities do not need to stop when a protected species is sighted in the proximity of construction if the construction activities are not in the water. The in-water moratorium prohibits pile installation and removal and activities associated with bridge construction and demolition when listed species are present in the water, but does not restrict terrestrial activity.

13. Terminal Groin Removal. With the Parallel Bridge Corridor (including the Preferred Alternative), the NCDOT would apply for a permit to retain the groin to protect the south end of the Oregon Inlet bridge. The groin would not be needed to protect a Pamlico Sound bridge.

14. Archaeological Resources Discovered During Construction. If any historic archaeological resources (i.e., historic watercraft) are encountered in the area west of Bodie Island during construction, construction work affecting the resource will cease immediately until the resource can be identified and assessed for National Register of Historic Places eligibility.

15. Construction of Future Phases Based on Available Funding. With the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred), it is NCDOT's intent to place a high priority on the implementation of Phase II. This intent recognizes the need to build Phase II, particularly in the Rodanthe 'S' Curves, Sandbag Area, and Canal Zone hot spots, as soon as it is practicable.

16. Monitoring Program. NCDOT considers the 2060 high erosion shoreline a reasonable assumption for current planning purposes, but also recognizes that decisions related to the implementation of Phases III and IV and the specific location of Phases III and IV would likely need to evolve with actual geomorphological change relative to the NC 12 easement, whether from changes in the characteristics of expected beach erosion, the possible changes of sound-side erosion at Oregon Inlet, accelerated sea level rise, or island breaching. With this in mind, NCDOT would implement a monitoring program on Hatteras Island in the project area whose particulars would be developed in association with representatives of the Pea Island National Wildlife Refuge, including development of decision-making criteria for translating monitoring findings into a decision to move forward with Phases III and IV.

17. Breach Response-Related Data Gathering Program. Recognizing the possibility that a breach could occur at the southern part of the Refuge prior to the completion of Phase II and four other locations exist in the project area that are geologically susceptible to a breach (three are bridged in Phase II and one in Phase III), NCDOT would conduct a breach response-related data gathering program focusing on the southern end of the Refuge.

18. Reduce the Potential Impacts from NC 12 Maintenance Prior to the Completion of Each Phase. Recognizing that storm-related NC 12 maintenance will occur before the completion of Phases II, III, and IV, particularly before the implementation of Phase II in the three hot spot areas, NCDOT would continue to work with the Refuge to reduce the potential impacts to the Refuge and NC 12 resulting from NC 12 storm-related maintenance.

19. Shortnose Sturgeon. Conservation measures to protect shortnose sturgeon would include no hopper dredging and measures to minimize habitat degradation. Such measures would include BMPs involving use, storage, and disposal of construction/demolition materials to minimize short-term turbidity or water quality degradation during over water construction in Oregon Inlet and during periodic maintenance. Construction and demolition activities associated with Phase I of the project would be completed as quickly as possible in order to minimize deterring spawning sturgeon from entering Oregon Inlet. In addition, the project would incorporate BMPs to reduce habitat degradation from stormwater runoff pollution.

Highway Design Branch, Project Development and Environmental Analysis Branch, Division 1, and Right-of-Way Branch

20. Utilities. Project development and construction activities would be coordinated with utility providers in the project area in order to prevent interruption of local utility services. The following utility providers currently serve the project area: Dare County (water service); Sprint Communications (telephone service); Charter Communications (cable television service); and Cape Hatteras Electric Membership Association (electric power service).

Highway Design Branch, Project Development and Environmental Analysis Branch, Division 1, and Geotechnical Unit

21. Use of Explosives During Construction. The use of explosives during construction is not anticipated. If explosives were needed to remove Bonner Bridge's piles, the NCDOT would coordinate with the appropriate environmental resource and regulatory agencies to develop a blasting program that would minimize adverse effects to the natural environment.

Project Development and Environmental Analysis Branch

22. Memorandum of Agreement. Prior to the release of the Record of Decision (ROD), FHWA will complete a Memorandum of Agreement with the State Historic Preservation Office and the Advisory Council on Historic Preservation in consultation with other consulting parties, as per the requirements of Section 106 of the Historic Preservation Act of 1966.

23. Seabeach Amaranth. Since the favored habitat of the seabeach amaranth is highly ephemeral, a survey of the project area would be conducted for the habitat of this species at least one year prior to initiating bridge construction activities. It would occur as needed for each construction phase of the Phased Approach/Rodanthe Bridge Alternative (Preferred).

Highway Design Branch, Project Development and Environmental Analysis Branch, Division 1, and Bridge Management Unit

24. Piping Plover. The NCDOT will implement the following nondiscretionary measures that include the terms and conditions outlined in the *Biological and Conference Opinion*s (USFWS, 2008):

    a. All construction equipment and personnel must avoid all bird closure areas within the Seashore and Refuge.

       All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 to July 15).

All future repair work on bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 to July 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for nesting plovers and avoided to the extent possible.

b. During the construction of Phases II, III and IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred), keep all construction equipment and activity within the existing right-of-way.

   Do not moor any construction barges within 300 feet (91.4 meters) of the following islands: Green Island, Wells Island, Parnell Island, Island MN, Island C, the small unnamed island immediately east of Island C, Island D, and Island G (see Figure 1 in the *Biological and Conference Opinion*s in Appendix E).

c. All dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission. The point of contact is Sue Cameron at 910-325-3602. If the dredge material is used outside the current defined action area, the action area is assumed to be expanded to cover the beneficial placement of the material.

d. To the maximum extent practical, while ensuring the safety of the traveling public, limit or avoid the use of road signs or other potential predator perches adjacent to plover nesting or foraging areas. Where signs or other structures are necessary, determine if alternative designs would be less conducive for perching on by avian predators (gulls, crows, grackles, hawks, etc.). For example, minimize or avoid the use of large cantilever signs in favor of smaller and shorter designs.

In addition, the project will incorporate the most current BMPs to reduce habitat degradation from stormwater runoff pollution as a conservation measure. Phase I of the project will be built at least 125 feet (38.1 meters) farther west of the Bonner Bridge and currently occupied piping plover habitat. Temporary facilities such as haul roads that affect proposed piping plover critical habitat will be removed as soon as possible.

25. Sea Turtles (green sea turtle, leatherback sea turtle, and loggerhead sea turtle). The NCDOT will implement the following nondiscretionary measures that include the terms and conditions outlined in the *Biological and Conference Opinion*s (USFWS, 2008):

    a. All construction equipment and personnel must avoid all marked sea turtle nests.

       Construction material and equipment staging areas must not be located seaward of the artificial dune.

       All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the US Coast Guard), must occur outside the nesting season (May 1 to November 15).

All future repair work of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the US Coast Guard) must occur outside the nesting season (May 1 to November 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for sea turtle nests and avoided to the extent possible.

b. Provide an opportunity for the USFWS or an USFWS designee to educate construction contractor managers, supervisors, foremen and other key personnel and resident NCDOT personnel with oversight duties (division engineer, resident engineer, division environmental officer, etc.) as to adverse effects of artificial lighting on nesting sea turtles and hatchlings, and to the importance of minimizing those effects.

c. During turtle nesting season (May 1 to November 15), use the minimum number and the lowest wattage lights that are necessary for construction.

   During turtle nesting season, portable construction lighting must be of the low-pressure sodium-vapor type.

   During turtle nesting season, utilize directional shields on all portable construction lights, and avoid directly illuminating the turtle nesting beach at night.

   During turtle nesting season, all portable construction lights must be mounted as low to the ground as possible.

   During turtle nesting season, turn off all lights when not needed.

d. For Phases II, III and IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred)**,** on the ocean side, design the bridge structure in a manner which will shield the beach on the east side from direct light emanating from passenger vehicle headlights. For the small portion of Phase I over land on Hatteras Island, retrofit the bridge structure at the time that Phase II connects with Phase I. The specific design of the bridge will be developed in consultation with the USFWS prior to re-evaluation of the environmental document for Phase II.

e. Avoid retrofitting the bridges and approach roads with permanent light fixtures in the future (excluding navigation lights required by the US Coast Guard).

In addition, NCDOT does not anticipate the use of explosives during construction or demolition of the existing bridge. The NCDOT contractor will use pipeline or clamshell dredging, rather than a hopper dredge to minimize effects to sea turtles. No permanent light fixtures will be installed on the bridge or the approaches (with the exception of navigation lights as required by the US Coast Guard).

Photogrammetry Unit and Project Development and Environmental Analysis Branch

26. Submerged Aquatic Vegetation (SAV) Survey. The dynamic nature of the area around Oregon Inlet results in ephemeral habitats, particularly in shallow water and shoreline areas. Consequently, the NCDOT would obtain new SAV information for use by the contractor in construction access planning.

Table of Contents

Volume 1

SUMMARY ..... **iii**

PROJECT COMMITMENTS ..... **xxxiii**

1.0 PURPOSE OF, AND NEED FOR, ACTION **1-1**

1.1 Project Need **1-1**
1.1.1 Need for Access across Oregon Inlet 1-3
1.1.2 Migration of the Natural Channel Gorge 1-5
1.1.3 Erosion of the Hatteras Island Shoreline 1-5

1.2 Project Purpose **1-6**

1.3 Background Information **1-6**
1.3.1 Project Area Setting and Land Use 1-6
1.3.2 Population Growth 1-7
1.3.3 Project History 1-7

1.4 Thoroughfare Planning **1-8**
1.4.1 Overview of the Thoroughfare Planning Process 1-8
1.4.2 Dare County Thoroughfare Plan 1-8
1.4.3 NCDOT Transportation Improvement Program 1-9

1.5 Transportation Network and Operating Characteristics **1-9**
1.5.1 Existing Road Network 1-9
1.5.2 Roadway Characteristics and Posted Speed 1-10
1.5.3 Sidewalks and Pedestrian Movements 1-11
1.5.4 Bicycles 1-11
1.5.5 Intersections and Access Control 1-11
1.5.6 Traffic Volumes 1-12
1.5.7 Levels of Service 1-15
1.5.8 Hurricane Evacuation 1-19

1.6 Modal Interrelationships **1-22**
1.6.1 Railroads 1-22
1.6.2 Airports 1-22
1.6.3 Transit 1-22
1.6.4 Water Travel (Ferry) 1-22

1.7 Summary **1-22**

2.0 ALTERNATIVES CONSIDERED **2-1**

2.1 No-Action Alternative **2-4**

2.2 1993 Draft Environmental Impact Statement Alternatives **2-5**
2.2.1 Basic Assumptions Used in 1991 and 1993 2-6
2.2.2 Summary of Alternatives Analysis Findings 2-7
2.2.3 Transportation Systems Management (TSM) Alternative 2-16

Table of Contents (continued)

2.2.4 Rehabilitation of Existing Bridge 2-16
2.2.5 1993 Parallel Bridge Corridor (1993 DEIS Preferred Alternative) 2-16
2.2.6 Ferry Alternative 2-21
2.2.7 Tunnel Alternative 2-26
2.2.8 East Bridge Corridor 2-30
2.2.9 West Bridge Corridor 2-33

2.3 2002 Pamlico Sound Bridge Corridor Alternatives Study 2-34
2.3.1 Screening Criteria 2-35
2.3.2 Corridor Alternatives 2-35
2.3.3 Evaluation Factors 2-37
2.3.4 Alternatives Analysis 2-39
2.3.5 Corridor Selected for Detailed Evaluation 2-42

2.4 2003 Pamlico Sound Bridge Corridor Alignment Alternatives Study 2-42
2.4.1 Screening Criteria 2-43
2.4.2 Alignment Alternatives within the Pamlico Sound Bridge Corridor 2-43
2.4.3 Evaluation Factors 2-47
2.4.4 Pamlico Sound Bridge Corridor Alignment Alternatives Analysis 2-50
2.4.5 Pamlico Sound Bridge Corridor Alignments Selected for Detailed Evaluation 2-54

2.5 2004 Additional Replacement Bridge Scenarios 2-54
2.5.1 Construction Cost 2-56
2.5.2 Comparison of Long-Span Bridges and 1993 Parallel Bridge Corridor 2-57
2.5.3 Pamlico Sound Bridge Corridor with Hatteras Island Connector 2-58
2.5.4 Conclusion 2-58

2.6 2005 Parallel Bridge Corridor with NC 12 Maintenance Alternatives Studies 2-58
2.6.1 Study Process 2-61
2.6.2 Coastal Studies 2-63
2.6.3 Evaluation of Potential Detailed Study Alternatives 2-65
2.6.4 Parallel Bridge Corridor Alternatives Defined for Detailed Evaluation 2-76

2.7 2006 Parallel Bridge Corridor with NC 12 Maintenance Alternatives Studies 2-77

2.8 2006 Long Bridge Operations and Safety Study 2-78
2.8.1 Operational Concerns 2-79
2.8.2 Weather 2-79
2.8.3 Crashes and Safety 2-81
2.8.4 Application to the Detailed Study Alternatives 2-81

2.9 Description of Pamlico Sound Bridge Corridor Alternative (Selected for Detailed Study) 2-81
2.9.1 Pamlico Sound Bridge Corridor Location 2-85
2.9.2 Bridge Characteristics 2-85

Table of Contents (continued)

2.9.3 Approach Roadway Characteristics 2-88
2.9.4 Rodanthe Terminus Options 2-90
2.9.5 Construction Procedures 2-91

2.10 Description of Parallel Bridge Corridor Alternatives with NC 12 Maintenance (Selected for Detailed Study) 2-96
2.10.1 Oregon Inlet Parallel Bridge Characteristics 2-101
2.10.2 NC 12 Maintenance Alternative Characteristics 2-114

2.11 Demolition and Removal of Bridges and Pavement 2-130
2.11.1 Demolition and Removal of Bonner Bridge 2-130
2.11.2 Removal of NC 12 Pavement 2-132
2.11.3 Future Demolition of Replacement Bridges 2-132

2.12 Costs and Funding 2-132
2.12.1 Project Costs 2-132
2.12.2 Bonner Bridge Demolition and Removal Costs 2-138
2.12.3 Other Public Costs 2-138
2.12.4 Capital Funding 2-142
2.12.5 Short-Term NC 12 Maintenance Costs Expected Prior to Implementation of the Phased Approach Alternatives 2-144

2.13 Environmental Protection during Construction and Demolition 2-144

2.14 Permits and Approvals 2-146

2.15 Preferred Alternative 2-148

3.0 AFFECTED ENVIRONMENT 3-1

3.1 Community 3-1
3.1.1 Regional Setting 3-1
3.1.2 Land Use 3-2
3.1.3 Land Use Planning 3-6
3.1.4 Zoning 3-12
3.1.5 Coastal Barrier Resources System 3-12
3.1.6 Population Characteristics 3-13
3.1.7 Economics 3-14
3.1.8 Community Services 3-16
3.1.9 Oregon Inlet Users 3-19
3.1.10 Underground Storage Tanks and Hazardous Waste 3-20
3.1.11 Farmland 3-22

3.2 Environmental Justice 3-22
3.2.1 Executive Order 12898 3-22
3.2.2 Concentrations of Minority and Low-Income Populations 3-22

3.3 Visual Characteristics 3-22
3.3.1 Rodanthe 3-23
3.3.2 Pea Island National Wildlife Refuge 3-25
3.3.3 Oregon Inlet 3-26

Table of Contents (continued)

3.4 Cultural Resources 3-27
3.4.1 Architectural and Landscape Resources 3-28
3.4.2 Archaeological Resources 3-32

3.5 Parks and Recreation/Wildlife Refuges 3-34
3.5.1 Cape Hatteras National Seashore 3-35
3.5.2 Pea Island National Wildlife Refuge 3-40

3.6 Coastal Conditions 3-49
3.6.1 Floodplains 3-49
3.6.2 Existing Coastal Conditions 3-51
3.6.3 Future Coastal Conditions 3-56

3.7 Natural Systems 3-68
3.7.1 Geology, Topography, and Soils 3-68
3.7.2 Surface Waters and Water Quality 3-68
3.7.3 Biotic Communities 3-74
3.7.4 Wetlands and Open Water Habitat 3-83
3.7.5 Unique and Rare Habitats 3-87
3.7.6 Water Resources, Fisheries, and Wildlife 3-88
3.7.7 Protected Species 3-102

3.8 Mineral Resources 3-109

3.9 Air Quality 3-110
3.9.1 Carbon Monoxide 3-110
3.9.2 Other Emissions 3-110
3.9.3 Regional Air Quality Standard Compliance 3-111

3.10 Noise 3-111
3.10.1 Fundamental Concepts of Roadway Noise 3-111
3.10.2 Noise Abatement Criteria 3-113
3.10.3 Ambient Noise Levels 3-114

4.0 ENVIRONMENTAL CONSEQUENCES 4-1

4.1 Community Impacts 4-2
4.1.1 Relocations 4-2
4.1.2 Land Use Planning 4-4
4.1.3 Coastal Barrier Resources System 4-8
4.1.4 Community Cohesion and Accessibility 4-8
4.1.5 Economics 4-10
4.1.6 Community Services 4-21
4.1.7 Oregon Inlet Users 4-26
4.1.8 Underground Storage Tanks and Hazardous Waste 4-27
4.1.9 Farmland 4-28

4.2 Environmental Justice 4-28

Table of Contents (continued)

4.3 Visual Impacts 4-28
4.3.1 Rodanthe 4-28
4.3.2 Pea Island National Wildlife Refuge 4-30
4.3.3 Oregon Inlet 4-31

4.4 Cultural Resources 4-33
4.4.1 Architectural and Landscape Resources 4-33
4.4.2 Archaeological Resources 4-40

4.5 Parks and Recreation 4-41
4.5.1 Cape Hatteras National Seashore Land Use Impacts on Bodie Island 4-41
4.5.2 Pea Island National Wildlife Refuge Land Use Impacts on Hatteras Island 4-42
4.5.3 Cape Hatteras National Seashore/Pea Island National Wildlife Refuge Recreational Use Impacts 4-44
4.5.4 Pamlico Sound Recreational Use Impacts 4-49

4.6 Coastal Conditions 4-49
4.6.1 Inlet Migration, Profile, and Gorge Alignment 4-49
4.6.2 Flooding During Major Storms 4-50
4.6.3 Performance of the Terminal Groin 4-52
4.6.4 Navigation Channel Dredging Operations 4-52
4.6.5 Natural Overwash 4-53
4.6.6 Accelerated Sea Level Rise 4-54
4.6.7 Island Breach in the Pea Island National Wildlife Refuge 4-56
4.6.8 Off-Shore Coastal Processes with the Phased Approach Alternatives 4-59

4.7 Natural Systems 4-74
4.7.1 Geology, Topography, and Soils 4-74
4.7.2 Surface Waters and Water Quality 4-75
4.7.3 Biotic Communities 4-84
4.7.4 Wetlands and Open Water Habitat 4-92
4.7.5 Unique and Rare Habitats 4-100
4.7.6 Fisheries and Wildlife 4-102
4.7.7 Positive Benefits of Allowing Natural Barrier Island Change 4-114
4.7.8 Impacts Prior to Implementation of Phases II to IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred) from Potential Short-Term or Emergency Actions 4-115
4.7.9 Protected Species 4-116
4.7.10 Avoidance, Minimization, and Compensatory Mitigation 4-129

4.8 Mineral Resources 4-141

4.9 Air Quality 4-141
4.9.1 Regional Air Quality 4-142
4.9.2 Microscale Air Quality Analysis 4-142
4.9.3 Potential Air Quality Impacts 4-144

Table of Contents (continued)

4.9.4 Air Quality Conformance 4-144
4.9.5 Mobile Source Air Toxics 4-145

4.10 Noise 4-150
4.10.1 Traffic Noise Model 4-151
4.10.2 Predicted Noise Levels 4-151
4.10.3 Noise Analysis 4-151
4.10.4 Project Noise Abatement 4-154

4.11 Energy 4-156

4.12 Indirect and Cumulative Impacts 4-158
4.12.1 Study Area 4-159
4.12.2 Directions and Goals 4-160
4.12.3 Notable Features 4-161
4.12.4 Other Potential Impact Causing Activities 4-162
4.12.5 Potential Indirect Impacts 4-165
4.12.6 Potential Cumulative Impacts 4-166

4.13 Construction 4-172
4.13.1 Traffic Maintenance 4-172
4.13.2 Air Quality 4-173
4.13.3 Noise 4-173
4.13.4 Lighting 4-175
4.13.5 Waste Disposal 4-175
4.13.6 Construction Access 4-177
4.13.7 Natural Resource Protection 4-179
4.13.8 Erosion Control 4-180
4.13.9 Waste Spill Contingency Planning 4-180
4.13.10 Geodetic Survey Markers 4-180

4.14 Relationship between Long-Term and Short-Term Uses/Benefits 4-181

4.15 Irreversible and Irretrievable Commitments of Resources 4-181

5.0 FINAL SECTION 4(F) EVALUATION 5-1

5.1 Description of Section 4(f) Properties 5-2
5.1.1 Cape Hatteras National Seashore 5-2
5.1.2 Pea Island National Wildlife Refuge 5-6
5.1.3 (Former) Oregon Inlet US Coast Guard Station 5-9
5.1.4 Rodanthe Historic District and Chicamacomico Life Saving Station 5-10

5.2 Use of Section 4(f) Properties 5-11
5.2.1 Cape Hatteras National Seashore on Bodie Island 5-11
5.2.2 Pea Island National Wildlife Refuge/Cape Hatteras National Seashore on Hatteras Island 5-15
5.2.3 (Former) Oregon Inlet US Coast Guard Station 5-19
5.2.4 Rodanthe Historic District – Including Chicamacomico Life Saving Station 5-20

Table of Contents (continued)

5.3 Avoidance Alternatives 5-23
5.3.1 Rehabilitate Bonner Bridge Avoidance Alternative 5-24
5.3.2 Bridge from Rodanthe to Roanoke Island Avoidance Alternative 5-25
5.3.3 Build the Replacement Bridge Completely within the Existing NC 12 Right-of-Way Avoidance Alternative 5-26

5.4 Least Harm Analysis 5-27
5.4.1 Ability to Mitigate Adverse Impacts and Relative Severity of Remaining Harm 5-28
5.4.2 Relative Significance of Each Section 4(f) Property 5-38
5.4.3 Views of Officials with Jurisdiction over Each Section 4(f) Property 5-38
5.4.4 Degree to Which Each Alternative Meets the Purpose and Need for the Project 5-40
5.4.5 After Reasonable Mitigation, the Magnitude of Any Adverse Impacts to Properties Not Protected by Section 4(f) 5-41
5.4.6 Substantial Differences in Costs among the Alternatives 5-42
5.4.7 Conclusion 5-44

5.5 Constructive Use 5-45
5.5.1 Methodology 5-46
5.5.2 Analysis of Proximity Impacts 5-49
5.5.3 Constructive Use Conclusion 5-58

5.6 All Possible Planning to Minimize Harm 5-58

5.7 Coordination 5-59

Chapter 1

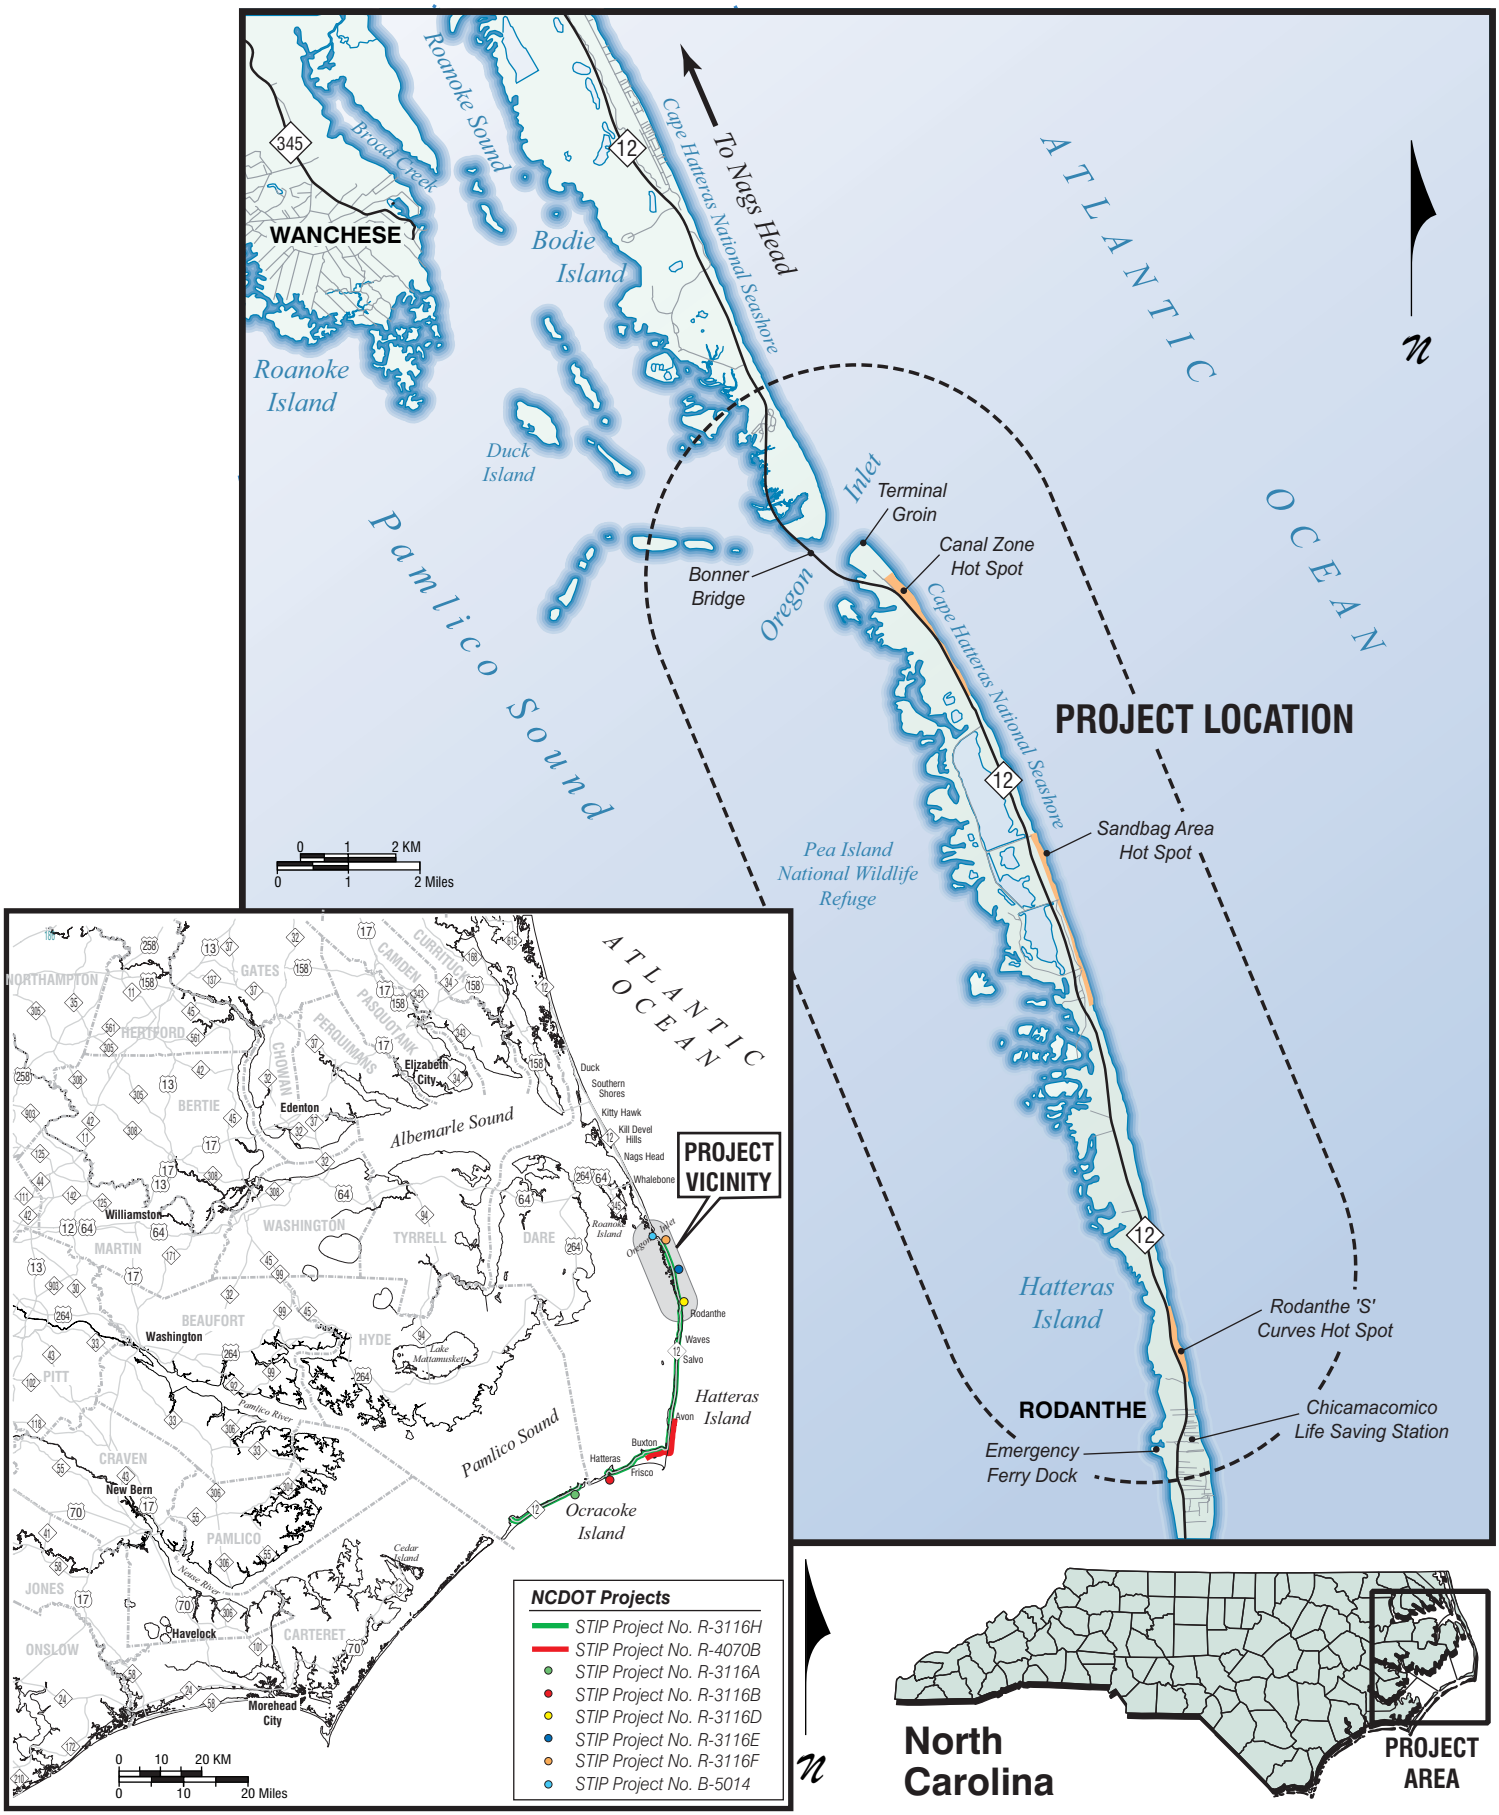
Purpose of, and Need for, Action

1.0 Purpose of, and Need for, Action

The North Carolina Department of Transportation's (NCDOT, 2008) *2009 to 2015 State Transportation Improvement Program* (TIP) includes the replacement of the Herbert C. Bonner Bridge (Bridge No. 11) over the Oregon Inlet in Dare County (TIP Project No. B-2500). Studies are underway in accordance with the requirements set forth in the National Environmental Policy Act (NEPA) of 1969, as amended. This purpose and need statement explains why the project should be implemented. The project location is illustrated in Figure 1-1.

The Bonner Bridge spans Oregon Inlet within North Carolina's Outer Banks and connects Bodie Island with Hatteras Island. The bridge provides the only highway connection of Hatteras Island and the mainland via NC 12 and US 64. The Bonner Bridge was built in 1962.

1.1 Project Need



The need for an Oregon Inlet crossing will continue past the end of the service life of the Bonner Bridge. A NCDOT Bridge Inspection Report from June 2006 rates the present condition of the bridge as "poor," with a sufficiency rating of two out of 100. This report also estimates the remaining practical service life of Bonner Bridge to be five years (as of 2007), indicating a need for extensive ongoing maintenance and rehabilitation. A planned rehabilitation project (TIP Project No. B-5014) is expected to increase the estimated practical service life to 10 years. The 2006 Bridge Inspection Report indicates there are places on the bridge that show deterioration of bridge girders and substructure. Replacement of the Bonner Bridge is needed for three reasons:

1. Continued demand for convenient daily and emergency access across the Oregon Inlet is expected.

2. The natural channel or gorge through the Oregon Inlet migrates. A replacement bridge needs to provide spans of sufficient height and width for navigation through the anticipated area of future natural channel migration, helping to reduce future dredging needs, dredging impacts, and the cost of dredging.

3. The southern terminus of the Bonner Bridge is north of portions of NC 12 currently threatened by shoreline erosion and overwash. Placing the southern terminus of a replacement bridge (or incorporating a long-term NC 12 maintenance and protection project) south of these areas will reduce the frequency of maintenance of these threatened segments of NC 12.

The following paragraphs describe these needs.

PROJECT LOCATION MAP

Figure 1-1

1.1.1 Need for Access across Oregon Inlet

The existing crossing provides the only highway access to Hatteras Island. The only other way to access the island is via the ferry between Ocracoke Island and Hatteras Island. The need for continued access to Hatteras Island, with a capacity equivalent to that provided by the Bonner Bridge, is reflected in the following ways:

- **Tourist use of Hatteras Island (including the use of Cape Hatteras National Seashore), use of the Pea Island National Wildlife Refuge, and Dare County's reliance on tourism as its primary industry.**

  Tourism is the number-one industry in Dare County and on Hatteras Island. The tourist industry creates a large number of local jobs and generates substantial revenue for both Dare County and the State of North Carolina. Sixty-one percent of the employment in Dare County relates to the tourism industry. Dare County promotes both tourism during the peak (summer) season, as well as the development of "shoulder" season tourism (in the spring and fall). The labor force in Dare County increases by approximately 75 percent between off-peak season and peak season. In 1999, the seasonal economic revenues represented more than 70 percent of the annual economy in Dare County (Outer Banks Chamber of Commerce, 2003). The abundant natural resources in Dare County will continue to be a major draw for tourists.

  Cape Hatteras National Seashore is home to many species of flora and fauna and a number of biotic communities. It is a popular local, state, and national vacation destination. Recreation visit statistics posted on the National Park Service (NPS) web site show that the Cape Hatteras National Seashore (including Bodie, Hatteras, and Ocracoke islands) had 2,237,378 recreational visitors in 2007. Visitors enjoy a variety of activities, including birding, fishing, surfing, windboarding, swimming, hiking, and attending interpretive programs offered by NPS rangers. The Pea Island National Wildlife Refuge reports 2.7 million visitors annually, including birders, canoeists, beach users, fishermen, and photographers (Pea Island National Wildlife Refuge web site, August 18, 2008). Eco-tourism, a concept of combining ecological awareness and tourism, has become a new marketing tool for all of northeastern North Carolina. Dare County supports the concept of combining natural resources and tourism to promote the area's ecological values (2003 *Dare County Land Use Plan*).

- **Reliance of the permanent Hatteras Island population on mainland goods and services.**

  The southern beaches on Hatteras Island are all part of unincorporated Dare County and feature the six recreational-oriented communities of Rodanthe, Waves, Salvo, Avon, Buxton, and Frisco (see Figure 1-1). Hatteras, a seventh community, is home to the Hatteras Inlet Ferry Terminal. Development in Hatteras reflects its status as a commercial fishing village, and a dominant commercial presence exists along NC 12. Hatteras serves as both a year-round community and a seasonal resort destination. The permanent population on Hatteras Island was 4,001 in 2000.

  Products and services involved with daily life on Hatteras Island are transported across the Bonner Bridge. All types of goods can be purchased on the island, but the selection currently is limited, necessitating regular shopping trips north across Bonner Bridge to Manteo or communities on Bodie Island (Nags Head, Kill Devil Hills, etc). The island residents rely heavily on repair and other services from the mainland. Residents, as well as visitors, of

Hatteras Island rely on off-island community services. Telephone and electric service are brought to Hatteras Island via Bonner Bridge.

On Hatteras Island, the communities of Avon, Buxton, Frisco, and Hatteras are served by the Dare County Water Department. The other Hatteras Island communities of Rodanthe, Waves, and Salvo rely on private wells, as well as the County's reverse osmosis plant for potable water.

Dare County provides trash collection for the unincorporated areas of Dare County. Refuse is removed from Hatteras Island via Bonner Bridge. Dare County owns and operates transfer stations in Buxton and Manteo. On-site septic tank and drainfield systems are the predominant methods of wastewater treatment on Hatteras Island.

Hospitals are located in Nags Head, North Carolina; Elizabeth City, North Carolina; Norfolk, Virginia; and Chesapeake, Virginia. Ambulance destinations always are off the island.

- **Hatteras Island and Ocracoke Island emergency evacuation requirements.**

  In 1992, the Dare County Emergency Management Control Group was established to administer the *Dare County Emergency Operation Plan*. The plan describes evacuation procedures in the event Dare County is evacuated because of the threat of hurricanes or other storm events. An underlying objective of the plan is to minimize physical damage, injury, and loss of life in the event of a hurricane strike. In such an event, the plan provides for both Hatteras and Ocracoke islands to be evacuated to Bodie Island via Bonner Bridge and, subsequently, to the mainland via US 64 and US 158. Therefore, Bonner Bridge is considered a critical evacuation route in the plan

  The 2001 US Army Corps of Engineers (USACE) Hurricane Evacuation Model estimated that, for a Category 3-5 hurricane during a period of tourist high occupancy in 2000, 9,530 vehicles could have been expected to evacuate via NC 12 on Hatteras Island. There would be approximately 14,761 evacuating vehicles on Bonner Bridge in response to a Category 3 – 5 storm during the peak tourist season in 2025.

  A 2005 hurricane evacuation study prepared for NCDOT (PBS&J, 2005) modeled 2004 and 2030 evacuation response times (time to move all evacuees through the road network) for North Carolina coastal areas. Clearance times for evacuees using US 64 to Columbia (the closest evacuation route for Hatteras Island residents and visitors) was 17.5 hours in 2004 (assuming 75 percent tourist occupancy and a Category 3 to 5 hurricane). This time is expected to rise to 26.4 hours by 2030. An 18-hour clearance time standard was adopted by the North Carolina Legislature in 2005 (NC Gen. Stat. § 136-102.7, "Hurricane Evacuation Standard"). However, the link in the coastal road system controlling the current and future clearance time when evacuating along US 64 is between Columbia, North Carolina in Tyrrell County and Mann's Harbor in Dare County and not NC 12 in the project area.

- **Travel demand.**

  The 2002 annual average daily traffic (AADT) volume over Bonner Bridge was estimated to be 5,400 vehicles per day (vpd). Summer peak season (June through August) daily traffic flows are substantially higher than the AADT. In 2002 during the peak summer season, average weekday traffic crossing the bridge was 8,000 vpd. Average weekend traffic carried in peak

season was 10,900 vpd. By 2025, these daily volumes are forecast to rise to 9,600 vpd (AADT), 14,200 vpd (summer average weekday), and 19,200 vpd (summer average weekend).

1.1.2 Migration of the Natural Channel Gorge

The Oregon Inlet channel migrates, and channel movement must be considered when determining the proper horizontal alignment of any replacement bridge. Since its opening during a storm in 1846, the midpoint of Oregon Inlet has migrated steadily southward just over two miles (3.2 kilometers) at an average rate of 70 feet (21.3 meters) per year. The history of Oregon Inlet's migration is punctuated by alternate widening and narrowing, typically in response to severe storms. Widening and narrowing of Oregon Inlet generally occurs because of erosion and accretion along the Bodie Island (north) shoulder of the inlet. Until construction of the terminal groin in 1989, the Hatteras Island shoulder moved steadily southward. Thus, most of the current variation in inlet width is the result of Bodie Island movement.

Like all active tidal inlets, Oregon Inlet requires periodic dredging to maintain a navigation channel; dredging also is required to maintain this channel such that it passes under the Bonner Bridge navigation span. The current natural inlet gorge is 30 to 40 feet (9 to 12 meters) deep.

1.1.3 Erosion of the Hatteras Island Shoreline

Shoreline erosion and ocean overwash threaten to sever segments of the NC 12 roadway for several miles south of Bonner Bridge.

In August 1991, the NCDOT sponsored a research project conducted by North Carolina State University to identify critical sections of North Carolina's coastal highways and options available for maintaining these highway corridors. The study concluded that NC 12 has six critical sections, or "hot spots," between Oregon Inlet and the southwestern tip of Ocracoke Island. Three of the hot spots are at the north end of Hatteras Island: Canal Zone, Sandbag Area, and Rodanthe 'S' Curves. The NCDOT has completed vulnerability studies (*NC 12 Shoreline Erosion Analysis, Canal and Sandbag Areas*, 2002) for the two northernmost hot spots, the Canal Zone and Sandbag Area (see Figure 1-1).

The northern Rodanthe area, including the Rodanthe 'S' Curves Hot Spot, has the highest erosion rates in the Bonner Bridge replacement project area, with a maximum rate of about 15 feet (4.6 meters) per year. Erosion rates in the Canal Zone and Sandbag Area hot spots are as high as 8 feet (2.4 meters) per year. (Overton and Fisher, June 2005).

In recognition of the need to address long-term maintenance of NC 12 on Hatteras and Ocracoke islands, a partnering agreement was formulated and adopted by the USACE, the NPS, the US Fish and Wildlife Service (USFWS), the National Marine Fisheries Service, the Federal Highway Administration (FHWA), the North Carolina Department of Environment and Natural Resources, Dare County, Hyde County, and the NCDOT. The Executive Committee and Interagency Task Force on the Transportation System on North Carolina's Outer Banks were established in October 1993 because of the partnering agreement. The Interagency Task Force's (titled the Outer Banks Task Force [OBTF]) mission has been to take an integral role in developing the long-term protection and maintenance plan for the transportation system on the Outer Banks. The Memorandum of Agreement (MOA) establishing the OBTF has expired, but the OBTF continues to meet to share information and to foster continued relationships.

In addition, the USACE is planning to conduct a feasibility study of Hatteras and Ocracoke islands to determine possible long-term solutions to the transportation problems that exist on both Hatteras and Ocracoke islands. NCDOT is the local sponsor for this Congressionally authorized feasibility study (TIP No. R-3116H). This study is currently unfunded by the US Congress.

1.2 Project Purpose

The purposes of the proposed project are to:

- **Provide a new means of access from Bodie Island to Hatteras Island for its residents, businesses, services, and tourists prior to the end of Bonner Bridge's service life.**

  Needs Addressed: Although Bonner Bridge is reaching the end of its service life, demand for convenient daily and emergency access across Oregon Inlet is expected to continue.

- **Provide a replacement crossing that takes into account natural channel migration expected through year 2050 and provides the flexibility to let the channel move.**

  Needs Addressed: The natural channel or gorge through Oregon Inlet migrates. A replacement bridge needs to provide spans of sufficient height and width for navigation through the anticipated areas of future natural channel migration, thereby helping to reduce future dredging needs. Construction of the replacement crossing west of Oregon Inlet where less sand movement occurs also could help reduce future dredging needs.

- **Provide a replacement crossing that will not be endangered by shoreline movement through year 2050.**

  Needs Addressed: The southern terminus of Bonner Bridge is north of portions of NC 12 threatened by shoreline erosion and overwash. Placing the southern terminus of a replacement bridge south of these areas, or including a long-term NC 12 maintenance and protection component, will reduce the need for frequency of maintenance of these threatened segments of NC 12. All the alternatives were ultimately developed for a service life through 2060.

1.3 Background Information

1.3.1 Project Area Setting and Land Use

The Herbert C. Bonner Bridge spans Oregon Inlet within North Carolina's Outer Banks (see Figure 1-1) and connects Bodie Island with Hatteras Island. The bridge provides the only highway connection of Hatteras Island and the mainland via NC 12 and US 64.

Oregon Inlet is within Dare County and is the northernmost inlet along the Outer Banks. The inlet was opened in 1846 by a severe storm and, after closing, reopened in 1864. The history of Oregon Inlet has been one of regular southward migration, accompanied by alternate widening and narrowing of the inlet. To maintain navigability of Oregon Inlet, maintenance dredging by the USACE has been necessary since 1960.

Prior to construction of Bonner Bridge in 1962, transport across Oregon Inlet was via ferry. The ferry was unable to keep pace as demand for transportation across the inlet increased, and the bridge was constructed to meet the increased demand. The bridge was opened to traffic in November 1963.

The project area includes three types of land use—Cape Hatteras National Seashore, Pea Island National Wildlife Refuge, and the unincorporated community of Rodanthe. Land use in the portion of Rodanthe within the project area includes vacation homes and commercial uses, a NCDOT emergency ferry dock, a community center, the Chicamacomico Life Saving Station (a National Register of Historic Places listed historic resource and museum), and the Rodanthe Historic District (eligible for inclusion in the National Register of Historic Places).

1.3.2 Population Growth

Dare County is experiencing substantial growth. Forecasts indicate that the population will continue to grow at a rapid rate over the next 20 years. The permanent population of Dare County was approximately 30,000 in 2000 and is expected to grow to approximately 44,000 by 2020, a 47 percent increase. The 2003 *Dare County Land Use Plan* indicates that the seasonal population peak for Dare County is approximately 200,000. US Census data for 2000 show that the Hatteras Island permanent population was approximately 4,000.

1.3.3 Project History

Since its construction in 1963, Bonner Bridge has required continual maintenance. Three major continuing problems requiring periodic maintenance are:

1. Deterioration of the bridge through extensive corrosion of the reinforcing steel as well as major spalling of concrete (fragments breaking off the face) on the supporting structures;

2. Scour (erosive force of moving water) of a depth great enough to affect the piles' ability to support the superstructure; and

3. Natural channel migration that results in the periodic need for boat traffic to pass beneath a span adjacent to the bridge's primary navigation span.

Maintenance projects associated with the correction of these problems began in 1965, when severe scour was discovered near the navigation span, and continue today. In 1978 and 1981, contracts to construct support bents at the Hatteras Island end of the bridge were let in response to a discovery that several bents had pile penetrations of less than 7 feet (2.1 meters). In 1989 and 1991, additional piles were installed at the Bodie Island end of the bridge. In 1989 and 1990, a terminal groin (rubble or rock mound structure), projecting 550 feet (167.7 meters) into Oregon Inlet, then turning and extending seaward perpendicular to the shoreline, was built on Hatteras Island to protect the southern bridge approach.

The bridge is also vulnerable to ship collision. This problem became apparent in October 1990. A hopper dredge used to maintain Oregon Inlet's channel struck Bonner Bridge and demolished several spans, forcing the bridge to be closed to traffic from October 1990 to February 1991. The bridge was not designed to withstand the impact of such a vessel.

A *Draft Environmental Impact Statement* (DEIS) for the replacement of Bonner Bridge was approved in November 1993. Public hearings were held on February 23 and 24, 1994. A preferred alternative was selected and a preliminary *Final Environmental Impact Statement* (FEIS) was prepared. Coordination with the USFWS related to Section 7 of the Endangered Species Act was not completed, and thus the FEIS was never finalized nor approved.

Trends in the 1990s and early 2000s in shoreline erosion, as well as overwash of NC 12 and other changes in the setting of the project resulted in the decision to prepare a *Supplemental Draft Environmental Impact Statement* (SDEIS) and assess additional alternatives for the bridge replacement. Following completion of the SDEIS in 2005, a Supplement to the SDEIS (SSDEIS) was prepared in 2007. The SSDEIS addressed the characteristics and potential direct, indirect, and cumulative impacts of two additional alternatives. The 2005 SDEIS and 2007 SSDEIS together make up the DEIS from which this FEIS was prepared.

The project area that includes both Oregon Inlet and NC 12 is shown in Figure 1-1. The project area is within the Cape Hatteras National Seashore, and the portion of the project area south of Oregon Inlet is also within the Pea Island National Wildlife Refuge. The community of Rodanthe is at the southern end of the project area.

1.4 Thoroughfare Planning

1.4.1 Overview of the Thoroughfare Planning Process

The thoroughfare planning process is a comprehensive transportation planning process that integrates urban area planning practices with local, regional, and statewide transportation planning practices. The process identifies transportation planning needs by evaluating land development and population growth trends in both rural counties and urbanized areas. The process begins through a cooperative effort between the NCDOT's Transportation Planning Branch and local planning officials. Socio-economic data, including business and residential area inventories, existing street inventories, identification of environmental constraints, and information about the history of the area, are collected. A base-year transportation model is built. Utilizing input from local planning officials, land development and population growth trends are projected and applied to the model. Through this modeling process and local knowledge of the area's socio-economic conditions, the thoroughfare planning team identifies transportation deficiencies and determines short- and long-term solutions for eliminating or diminishing those deficiencies.

1.4.2 Dare County Thoroughfare Plan

The *Dare County Thoroughfare Plan*, last updated in 1988, covers a planning period through 2010. This document is considered out-of-date and is no longer used for transportation planning purposes. (Personal communication, 2003, Donna Creef, Dare County Planning Department.) The 1988 plan, however, did list the Herbert C. Bonner Bridge among those bridges considered structurally deficient or functionally obsolete in Dare County. An update to the plan is not currently scheduled.

1.4.3 NCDOT Transportation Improvement Program

This project is included as TIP Project No. B-2500 in the NCDOT's *2009 to 2015 State* TIP covering the period from Federal Fiscal Year (FFY) 2009 (October 2008) through FFY 2015 (September 2015). The additional transportation projects that are near the proposed project are depicted in Figure 1-1 and listed below:

Project R-3116A	Planning for interim measures to protect NC 12 from sand and ocean overwash at Ocracoke Island.
Project R-3116B	Planning for interim measures to protect NC 12 from sand and ocean overwash at Hatteras Village.
Project R-3116D*	Relocation of NC 12 from north of Rodanthe to south of the Refuge Boundary (Rodanthe 'S' Curves Hot Spot) to protect roadway from sand and ocean overwash.
Project R-3116E*	Planning for interim measures to protect NC 12 from sand and ocean overwash at the Sandbag Area Hot Spot.
Project R-3116F*	Planning for interim measures to protect NC 12 from sand and ocean overwash at the Canal Zone Hot Spot. (This project is combined with Project R-3116E for planning purposes.)
Project R-3116H	Planning and environmental studies for the long-term maintenance of NC 12 from Ocracoke Island to the southern terminus of Bonner Bridge. A joint NCDOT/USACE feasibility study (Hatteras and Ocracoke islands, NC) was underway but is currently not funded by the US Congress.
Project R-4070B	Planning and environmental studies for maintaining NC 12 from Buxton to Avon. Programmed for planning and environmental studies only.
Project B-5014	Repairs to Bridge No. 11 (Bonner Bridge over Oregon Inlet) in FFY 2007 and FFY 2008.

* Project not listed in the TIP and is currently unfunded. Planning studies were underway, but they are currently (2008) on hold and are not expected to be implemented given that the Phased Approach/Rodanthe Bridge Alternative (Preferred) is a long-term solution to protecting NC 12 from sand and ocean overwash.

1.5 Transportation Network and Operating Characteristics

1.5.1 Existing Road Network

Bridges comprise a key component of the transportation infrastructure and serve as entryways to Dare County. According to the *Dare County Land Use Plan* (2003), most travel within the County occurs on two arterial routes, NC 12 and US 158. US 158 extends north-south from Southern Shores to the Whalebone area of Nags Head. NC 12 extends north-south from

Currituck County to Hyde County on Ocracoke Island. Movements on and off the Outer Banks to the mainland are restricted to US 64 and US 158. Ferry service between Hatteras Village and Ocracoke Island also serves as a means for entering and leaving Dare County.

The Herbert C. Bonner Bridge, which links NC 12 on Hatteras and Bodie islands, provides the only roadway link for travelers driving a vehicle on and off Hatteras Island.

1.5.2 Roadway Characteristics and Posted Speed

NC 12 is designated as a major collector route by both the Dare County and the NCDOT Functional Classification Systems. NC 12 is also part of the National Highway System and is classified as an Intermodal Terminal Connector. NC 12 between the Hatteras Ferry Terminal and US 158 near Nags Head also has been designated as a Strategic Highway Corridor (SHC) by the North Carolina Board of Transportation. The purpose of the SHC initiative is to provide a network of high-speed, safe, reliable highways throughout North Carolina for the efficient movement of people and goods. These corridors are critical to statewide mobility and connectivity and promote a vision of modern transportation, supportive of economic opportunities, and environmental excellence. The initiative offers NCDOT and its stakeholders an opportunity to consider long-term vision when making land use decisions and design and operational decisions on the highway system. The creation of a long-term vision identifies the ultimate desired facility type (freeway, expressway, boulevard, or thoroughfare) for each corridor. The section of NC 12 between the Hatteras Ferry Terminal and US 158 is envisioned to remain as a thoroughfare (the functional purpose of a thoroughfare is to provide a moderate to low level of mobility, with a higher level of access). NC 12 is part of Corridor 55, which connects the Hatteras, Kitty Hawk/Kill Devil Hills/Nags Head area with the Hampton Roads, Virginia, area (a length of approximately 120 miles [193 kilometers]) using portions of NC 12, US 158, and NC 168.

The NCDOT's right-of-way for the portion of NC 12 through the Cape Hatteras National Seashore (on Bodie Island) is on a right-of-way that the State of North Carolina retained title to and control of in 1952, when the State deeded land it had acquired for creation of the Seashore to the US Department of the Interior (i.e., the NPS). The NCDOT's right-of-way for NC 12 through the Pea Island National Wildlife Refuge (on Hatteras Island) is on a permanent easement granted to the State of North Carolina in 1954 by the US Department of the Interior (i.e., the USFWS) for the purpose of "construction, operation, and maintenance of a public road across the Pea Island National Wildlife Refuge." This easement is granted to the State of North Carolina "so long as it shall continue to use the same for highway right-of-way purposes." Within the project area, NC 12 is two lanes with unpaved shoulders. The NCDOT easement or right-of-way for NC 12 in the project area is 100 feet (30.5 meters) wide, except for approximately 600 feet (182.9 meters) in Rodanthe where the right-of-way is 60 to 68 feet (18.3 to 20.7 meters) wide.

Bonner Bridge is 12,864 feet (3,921 meters) long (or 2.44 miles [3.92 kilometers]), with a navigation span providing 65 feet (19.8 meters) of vertical clearance above mean high tide and 130 feet (39.6 meters) horizontal clearance between fenders. An adjacent span with 90 feet (27.4 meters) of horizontal clearance often also is used for navigation as the result of natural channel movement. A 17-foot (5.2-meter) under-clearance at mean sea level is typical for the north and south approaches. The roadway has a 28-foot (8.5-meter) clear roadway with two 12-foot (3.7-meter) lanes and two feet (0.6 meter) of lateral clearance on each side. The total outside width of the bridge is 33.3 feet (10.1 meters), including the 2.6-foot-wide (0.8-meter-wide) bridge rails on both sides of the bridge. In addition, the Bonner Bridge has 5.3-foot-wide (1.6-meter-wide)

fishing catwalks attached to the outside of the bridge on both sides near the shoreline, but the catwalks do not extend completely across Oregon Inlet.

The bridge was constructed on a curved alignment that extends across Oregon Inlet 4,000 feet (1,219 meters) inland of the Atlantic Ocean front. The alignment is shown in Figure 1-1. This curved alignment was selected in the early 1960s under the assumption that it would protect the structure from the ocean during storms, and because calmer waters facilitated construction. This alignment also allowed large vessels that could not clear the navigational span to find shelter inside Oregon Inlet during storms. The location of the navigation span was selected in anticipation of a jetty stabilization project for the Oregon Inlet, which was to follow the bridge construction by five to ten years. The jetty project was never built. As indicated in Section 1.1, Bonner Bridge is nearing the end of its service life.

The posted speed limit on NC 12, including Bonner Bridge, is 55 miles per hour (mph) (88 kilometers per hour [kph]), and passing is permitted where sight distances allow.

1.5.3 Sidewalks and Pedestrian Movements

There are no sidewalks in the project area. Visitors to the Cape Hatteras National Seashore (Seashore) and the Pea Island National Wildlife Refuge (Refuge) frequently stop on the side of the road to walk over the sand dunes east of NC 12 to reach the Atlantic Ocean. Wildlife trails used by Refuge visitors are located west of NC 12 near the Refuge Visitor Center and at the Refuge's southern border. These trails do not cross NC 12. Pedestrians cross NC 12 at Rodanthe to get from vacation homes to the beach, historic sites, and commercial recreation facilities and other commercial uses. There are no marked crosswalks in Rodanthe.

1.5.4 Bicycles

Two designated bicycle routes cross Oregon Inlet on Bonner Bridge. A national bicycle touring organization, Bikecentennial, distributes maps and leads tours on the first route, which is a multi-state route from Virginia to Florida. This route, called the North-South Atlantic Coast Bikeway, passes through North Carolina on NC 12 along the Outer Banks, including Bonner Bridge. The route extends along the East Coast from Maine to Florida and includes most portions of the Wright Brothers Bikeway, currently running from Corolla in Currituck County at its north end, through Dare County, and on to Ocracoke in Hyde County at its south end.

The NCDOT Bicycle and Pedestrian Division has designated a second route along this portion of NC 12 as part of a loop around the Pamlico Sound. Maps of this route are distributed by the Bicycle Program as part of a brochure entitled, "Around Pamlico Sound: Bicycling North Carolina's Outer Banks Region."

1.5.5 Intersections and Access Control

There is no access control on NC 12 in the project area. Project area intersections on NC 12 include:

- The driveway to the Oregon Inlet Marina and Fishing Center and an access road to a Seashore campground at the northern end of the project area on Bodie Island;

- The driveway to the Hatteras Island parking lot that serves persons who fish off the Bonner Bridge catwalks;

- Old NC 12 (SR 1257), which is the road that leads to the (former) US Coast Guard Station at the north end of Hatteras Island;

- Periodic parking lots for visitors to the Refuge and the Seashore, including the driveway to the Refuge Visitor Center; and

- Local streets within Rodanthe that serve residential developments and the NCDOT's emergency ferry dock.

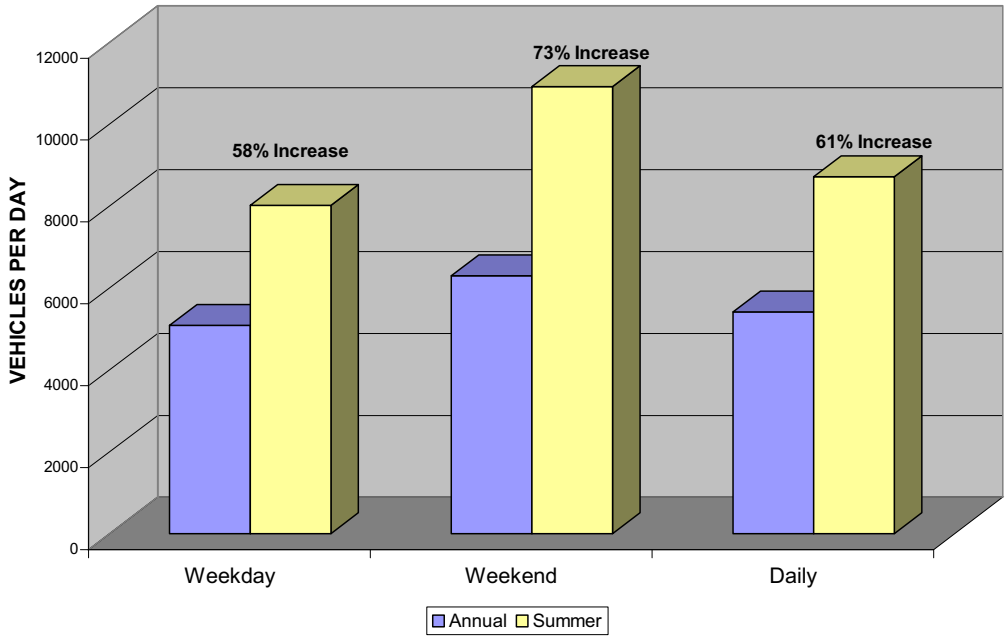
There are no signalized intersections in the project area.

1.5.6 Traffic Volumes

1.5.6.1 Existing Trends (2002)

Existing traffic data for NC 12 are available from an automatic traffic counter station (# A2701) at the north end of the Bonner Bridge. Traffic volumes collected in 2002 at count station A2701 are summarized in Table 1-1.

Table 1-1. 2002 Traffic Volumes on NC 12 at Bonner Bridge



Time Period	Northbound (vpd)	Southbound (vpd)	Total (vpd)
Annual Average Daily Traffic (AADT)	2,700 (50.0% of total)	2,700 (50.0% of total)	5,400
Annual Average Weekday Traffic	2,500 (49.0%)	2,600 (51.0%)	5,100
Annual Average Weekend Traffic	3,300 (52.4%)	3,000 (47.6%)	6,300
Summer Average Daily Traffic	4,400 (50.0%)	4,400 (50.0%)	8,800
Summer Average Weekday Traffic	3,900 (48.8%)	4,100 (51.2%)	8,000
Summer Average Weekend Traffic	5,700 (52.3%)	5,200 (47.7%)	10,900
Summer Average Saturday Traffic	6,400 (50.4%)	6,300 (49.6%)	12,700
Peak Day Traffic	7,900 (55.6%)	6,300 (44.4%)	14,200

Notes:
- Summer data are based on traffic counts for the months of July and August in 2002.
- The peak day was Saturday, July 6, 2002.

NC 12 carried an AADT of 5,400 vehicles per day (vpd) in 2002. As noted in the table, there is a clear distinction between weekend and weekday traffic throughout the year. Weekend traffic is 16 percent higher than the AADT figure, with 52.4 percent traveling northbound, reflecting returning tourist traffic traveling to the north. During weekdays, the traffic volume is six percent lower than the AADT figure with a similar pattern of heavier southbound movement or inbound trips.

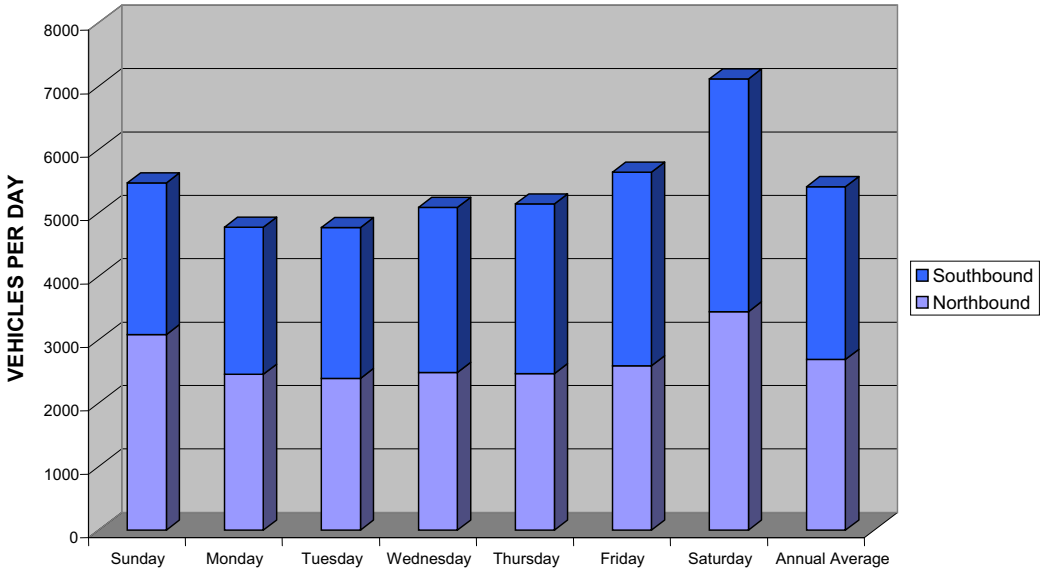
Table 1-1 also shows the daily traffic volume pattern along NC 12 during the summer months (July and August). As depicted in Figure 1-2, traffic volumes during the summer months are higher than average annual conditions, reflecting a strong seasonal variation in traffic patterns. In 2002, the daily weekend traffic along NC 12 was 73 percent greater than the annual traffic, with volume averaging 10,900 vehicles during summer weekend. For average daily traffic, there are 3,300 additional vehicles (61 percent) on the roadway during the summer season compared to the annual estimate.

Figure 1-2. Comparing Annual and Summer Traffic at Bonner Bridge

The highest daily traffic volume on NC 12 at Bonner Bridge was 14,270 vehicles; this was observed on Saturday, July 6, 2002.

In addition to high seasonal variation, NC 12 experiences daily traffic variation. This daily variation is depicted in Figure 1-3 for AADT and in Figure 1-4 for the summer peak season. The maximum daily volume spread is 2,340 vehicles, or 49 percent. During the summer peak season, the maximum daily volume spread is 5,500 vehicles, or 77 percent.

Figure 1-3. Annual Average Daily Traffic by Day of the Week at Bonner Bridge



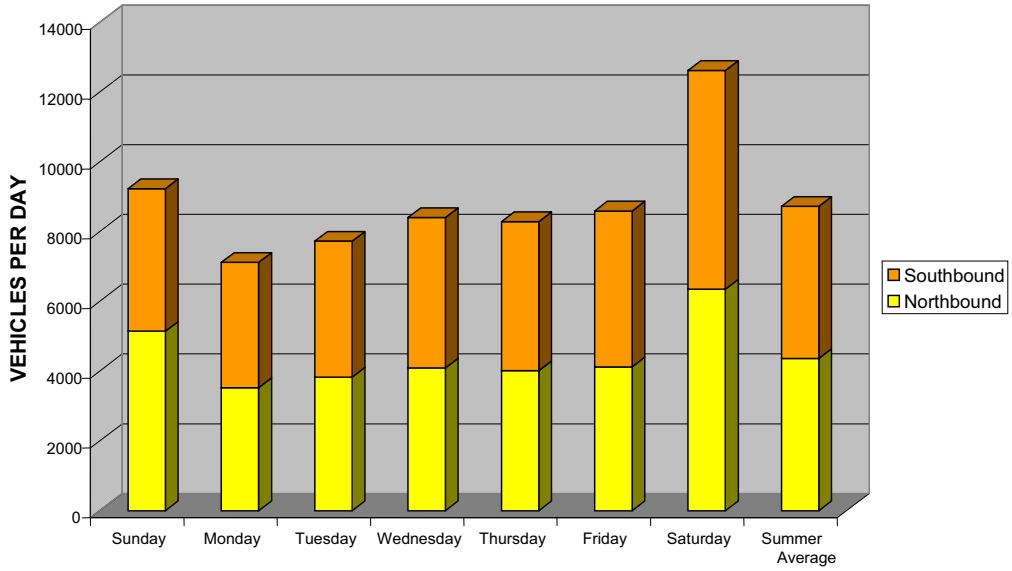


Figure 1-4. Peak Summer Daily Traffic by Day of the Week at Bonner Bridge

1.5.6.2 Future Volumes (2025)

Projected 2025 traffic volumes are presented in Table 1-2. Future traffic projections were estimated for year 2025 using the uniform growth rate approach. The traffic growth rate was estimated to be 2.5 percent per year. This is consistent with the traffic forecast performed for the 1993 DEIS, as well as NCDOT forecasts for other nearby projects, area population projections, historic traffic growth, area visitor forecasts, and the development potential of available parcels on Hatteras Island.

Table 1-2. 2025 Traffic Volumes on NC 12 at Bonner Bridge

Time Period	Northbound (vpd)	Southbound (vpd)	Total (vpd)
Annual Average Daily Traffic (AADT)	4,800	4,800	9,600
Annual Average Weekday Traffic	4,400	4,600	9,000
Annual Average Weekend Traffic	5,800	5,400	11,200
Summer Average Daily Traffic	7,700	7,700	15,400
Summer Average Weekday Traffic	6,900	7,300	14,200
Summer Average Weekend Traffic	10,100	9,100	19,200
Summer Average Saturday Traffic	11,200	11,100	22,000
Peak Day Traffic	14,000	11,200	25,200

1.5.7 Levels of Service

Existing and future levels of service (LOS) along NC 12 were estimated based on the two-way, two-lane methodology described in the *Highway Capacity Manual* (HCM) (Transportation Research Board, 2000).

LOS is a qualitative measure that characterizes the operational conditions within a traffic stream and represents the perception of traffic service by motorists and passengers. The different levels of service characterize these conditions in terms of such factors as vehicle speed, travel time, freedom to maneuver, traffic interruptions, comfort, and convenience. Six levels, represented by the letters A through F, are used to measure level of service. For roadways, LOS A indicates no congestion and LOS F represents more traffic demand than available road capacity and extreme delays.

Table 1-3 provides a general description of various levels of service for roadways as given in the HCM, as well as descriptions for unsignalized two-way stop intersections. Specific level of service definitions vary for two-lane highways, multi-lane highways, and intersections. In addition, the level of service for signalized and unsignalized intersections cannot be compared directly. In general, a poor level of service rating still can be considered acceptable for an unsignalized intersection. This is because the unsignalized intersection analysis is based upon the delay for minor street drivers as they await sufficient gaps in major street traffic. The signalized intersection analysis provides an overall average delay and level of service for the entire intersection.

Traffic operations on two-lane, two-way roadways are subjected to lane changing and passing in the opposing lane. As a result, the HCM approach uses a passing capacity that is dependent on the peak-hour traffic volume in both directions of travel. Consequently, LOS for a two-lane roadway is defined based on two primary measures. These are:

- Average travel speed; and
- Average percentage of travel time that vehicles must travel in platoons (groups of vehicles) behind slower vehicles because of the inability to pass those slow vehicles (percent time-spent-following).

Table 1-3. Level of Service Criteria

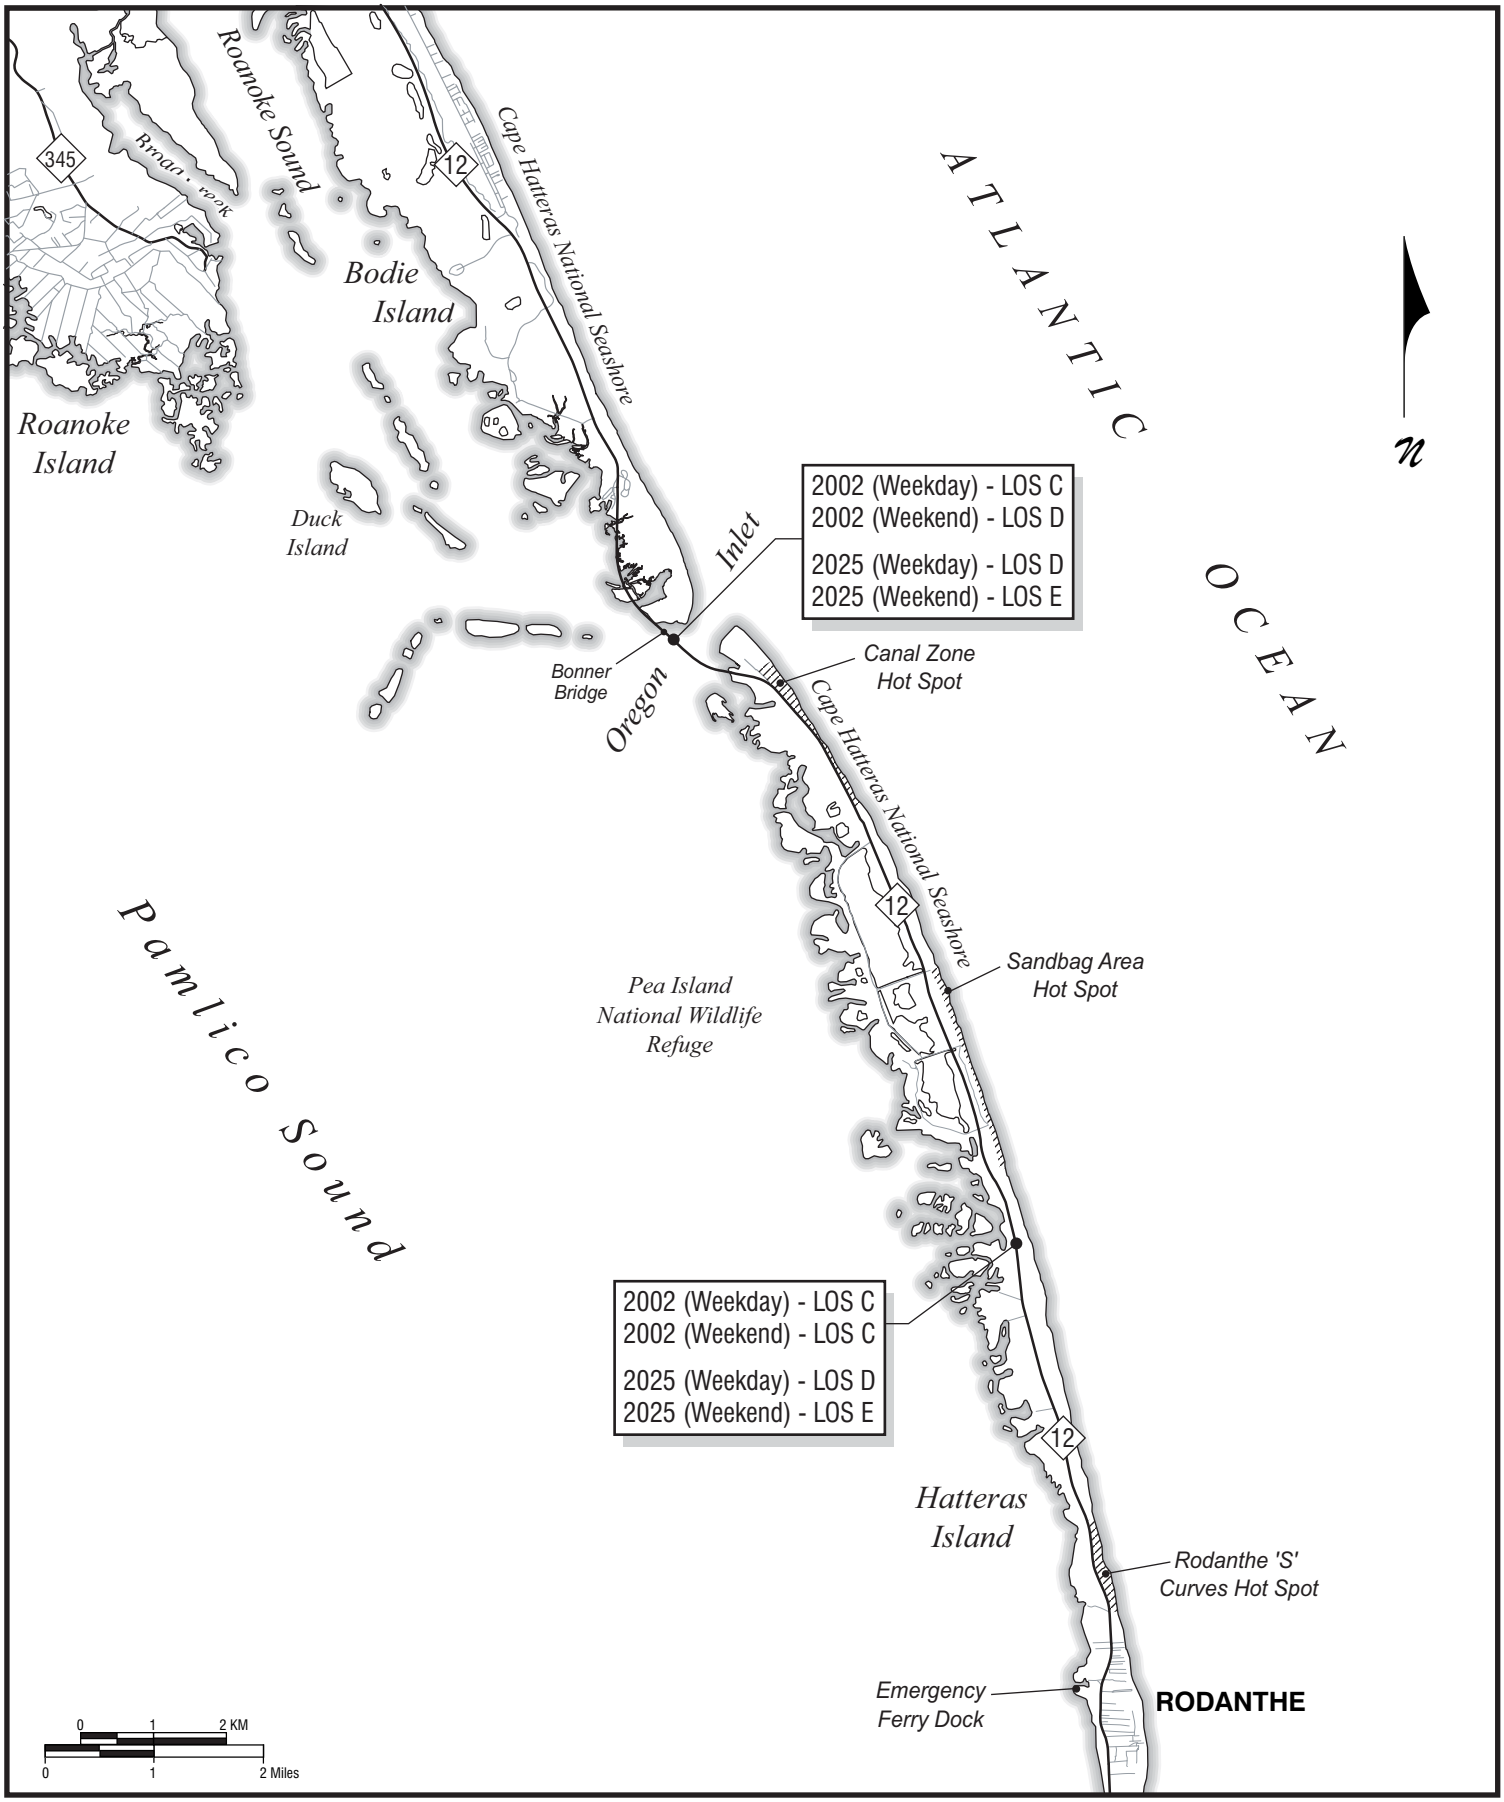
Level of Service	Traffic Flow on Roadways	Delay at Two-Way Stop Intersection
A	Free flowing traffic with little or no delays.	<=5 sec
B	A stable flow with few congestion-related restrictions on operating speed.	5-10 sec
C	Stable flow but with more restrictions on speed and changing lanes.	10-20 sec
D	Approaches unstable conditions and passing becomes extremely difficult. Motorists are delayed an average of 75 percent of the time.	20-30 sec
E	The capacity of a roadway. Passing is virtually impossible, speeds drop when slow vehicles or other interruptions are encountered.	30-45 sec
F	Heavily congested flow with traffic demand exceeding the capacity of the highway.	>45 sec

A traffic capacity analysis was performed for two roadway types and locations encountered within the project area. One location was within the Pea Island National Wildlife Refuge south of the bridge, and the other was on the Bonner Bridge structure. Although the traffic volumes are nearly identical for the two locations, it is necessary to analyze both cases separately because of their unique operational characteristics and geometric differences. These differences include shoulder widths, percent no passing zones, and access points per mile, which affect average travel speed and percent time-spent-following. Table 1-4 details these differences, as well as other key inputs assumed for the capacity analysis.

Table 1-4. Highway Capacity Analysis Variable Comparison

Analysis Variable	Mainland	Bonner Bridge
Shoulder Width	8 feet (2.4-meters)	2 feet (0.6-meters)
Lane Width	12 feet (3.7-meters)	12 feet (3.7-meters)
Highway Class	II	II
Directional Split	60%	60%
Peak Hour Factor	0.88	0.88
Truck Percentage	6%	6%
% No Passing Zone	20%	50%
Access Points Per Mile	2	0

Table 1-5 shows a summary of existing and future LOS for Bonner Bridge during five time periods:



1. Average Weekday;
2. Average Weekend;
3. Peak Season Weekday;
4. Peak Season Weekend; and
5. Peak Season Saturday.

Table 1-5. Level of Service (LOS) on Bonner Bridge

Time Period	Peak Hour Traffic Volume (vehicles per hour [vph])	Average Travel Speed (mph)	Percent Time-Spent-Following	LOS
EXISTING (2002)				
Average Weekday	450	50.3	54.9%	B
Average Weekend	600	49.6	60.0%	C
Peak Season Weekday	690	49.1	61.9%	C
Peak Season Weekend	1,030	46.8	72.6%	D
Peak Season Saturday	1,180	45.8	76.0%	D
FUTURE (2025)				
Average Weekday	790	48.4	65.4%	C
Average Weekend	1,060	46.6	73.4%	D
Peak Season Weekday	1,210	45.6	76.7%	D
Peak Season Weekend	1,810	40.6	86.9%	E
Peak Season Saturday	2,080	38.2	89.9%	E

Similarly, Figure 1-5 and Table 1-6 show the existing and future LOS for the NC 12 roadway segment immediately south of Bonner Bridge.

Table 1-5 shows that Bonner Bridge operates at an unstable flow condition (LOS D) during peak summer weekend because motorists are delayed in platoons for nearly 73 percent of their travel time, as passing becomes extremely difficult. This peak summer weekend condition is projected to worsen to LOS E by 2025, when passing would be virtually impossible and platooning would increase. By 2025, the Bonner Bridge is also projected to operate at LOS D, with an extremely difficult passing environment during a peak summer weekday or an average weekend.

PEAK SEASON LEVEL OF SERVICE

Figure 1-5

Table 1-6. Level of Service (LOS) on NC 12 South of Bonner Bridge

Time Period	Peak Hour Traffic Volume (vph)	Average Travel Speed (mph)	Percent Time-Spent-Following	LOS
EXISTING (2002)				
Average Weekday	450	53.6	49.0%	B
Average Weekend	600	52.6	55.1%	C
Peak Season Weekday	690	52.0	57.8%	C
Peak Season Weekend	1030	49.5	69.5%	C
Peak Season Saturday	1180	48.4	73.3%	D
FUTURE (2025)				
Average Weekday	790	51.2	61.6%	C
Average Weekend	1060	49.3	70.3%	D
Peak Season Weekday	1210	48.1	74.1%	D
Peak Season Weekend	1810	42.9	85.8%	E
Peak Season Saturday	2080	40.5	89.0%	E

Table 1-6 shows that NC 12 south of the Bonner Bridge is projected to operate at similar LOS conditions by 2025, but with slightly less platooning and a higher travel speed than on Bonner Bridge.

1.5.8 Hurricane Evacuation

The residents and visitors of Hatteras Island and Ocracoke Island, two hurricane-prone coastal communities in North Carolina, travel on NC 12 and across Bonner Bridge when evacuating the area during a storm warning. Consequently, the Bonner Bridge serves an important function in emergency evacuation and helps maintain the clearance time (i.e., time to evacuate all participating population during a hurricane storm).

The evacuation clearance time depends on the following key emergency planning variables:

- Type of hurricane storm (Categories 1 – 5, see Table 1-7);
- Tourist Season (peak season with high occupancy vs. off-peak season with low occupancy);
- Location and number of people living in permanent occupied units, mobile home units and seasonal tourist units;
- Rates of participation in the evacuation;

Table 1-7. Hurricane Categories[1]

Storm Type	Wind Speed	Damage Potential
Category 1 (Weak)	74 – 95 mph (118 – 153 kph)	Minimal damage to vegetation
Category 2 (Moderate)	96 – 110 mph (154 – 177 kph)	Moderate damage to houses
Category 3 (Strong)	111 – 130 mph (178 – 209 kph)	Extensive damage to small buildings
Category 4 (Very strong)	131 – 155 mph (210 – 247 kph)	Extreme structural damage
Category 5 (Devastating)	> 155 mph (> 248 kph)	Catastrophic building failures possible

[1] Hurricanes are rated in intensity on the Saffir-Simpson Hurricane Scale based on wind speed, pressure, storm surge, and damage potential. This list from the Federal Emergency Management Agency provides a basic description.

- Origin and destination of the evacuation trip;
- Use of vehicles; and
- Service capacity of the critical roadway links along major evacuation routes.

The above emergency planning variables were used to develop a Hurricane Evacuation Model for the USACE's Wilmington District in 2001. The model automated the steps involved in calculating clearance times for different storm types during the peak and off-peak tourist seasons. The Hurricane Evacuation Model uses demographic data from the 2000 Census, which can be updated to a future year. The 2001 evacuation model estimated that for a Category 3-5 hurricane during a period of tourist high occupancy in 2000, 9,530 vehicles could be expected to evacuate via NC 12 on Hatteras Island.

Year 2025 modeling results for the Hatteras and Ocracoke islands are presented in Table 1-8 for Categories 1 – 2 and Categories 3 – 5 hurricanes. The table shows that there would be approximately 14,761 evacuating vehicles on the Bonner Bridge in response to a Category 3 – 5 storm during the peak tourist season in 2025, an indicator of the continued importance of Bonner Bridge to hurricane evacuation.

A 2005 hurricane evacuation study prepared for NCDOT (PBS&J, 2005) modeled 2004 and 2030 evacuation response times (time to move all evacuees through the road network) for North Carolina coastal areas. Data are not presented in the report for Hatteras Island alone but instead by major route off the Outer Banks. The number of evacuating vehicles, and the clearance time in hours, for 2004 and 2030 on the two routes off the Outer Banks are presented in Table 1-9. Both the number of vehicles evacuating and clearance times are expected to rise from 2004 to 2030.

Table 1-8. Year 2025 Hurricane Evacuation Analysis by Zones

Evacuation Zone	Evacuating People		Evacuating Vehicles	
	Off-Peak Tourist Season	Peak Tourist Season	Off-Peak Tourist Season	Peak Tourist Season
CATEGORY 1–2 HURRICANE				
Hatteras Island	17,152	38,165	5,679	12,246
Ocracoke Island	1,979	4,832	724	1,723
Total	**19,131**	**42,997**	**6,403**	**13,969**
CATEGORY 3–5 HURRICANE

1.6 Modal Interrelationships

1.6.1 Railroads

Railroad service is not available in Dare County.

1.6.2 Airports

Dare County Regional Airport is a publicly owned, general aviation airport in Manteo on Roanoke Island, outside the project area. The airport is capable of serving most regional jets.

There are three publicly owned airstrips for private aircraft on the Outer Banks, but not within the project area. One is further north in Kill Devil Hills. The other two are further south on Hatteras and Ocracoke islands. Each airstrip is owned and managed by the NPS and operates during daylight hours only.

No commercial passenger or freight air service is available in the project area.

1.6.3 Transit

There is no local or regional bus service provided in the project area. Taxi service is available. Para-transit services are provided by Dare County to serve elderly and handicapped persons.

1.6.4 Water Travel (Ferry)

Six vessels operate at no charge to users between the southern end of Hatteras Island and Ocracoke Island across Hatteras Inlet. In 2000, more than 25,800 ferry trips carrying 989,435 travelers were made between the two islands. On Ocracoke Island, a tolled ferry service is provided south to Cedar Island and north to Swan Quarter on the Hyde County mainland. Ferry schedules are designed to accommodate expected vehicular demand, which is highest in the summer months. Emergency ferry landings are located at Rodanthe on Hatteras Island and at Stumpy Point on the mainland. These would be used by ferries if access to Hatteras Island via the Bonner Bridge were to be disrupted.

1.7 Summary

The North Carolina Department of Transportation's *2009 to 2015 TIP* includes the replacement of the Herbert C. Bonner Bridge (Bridge No. 11) over the Oregon Inlet in Dare County (TIP Project No. B-2500). The need for a crossing of the Oregon Inlet will continue past the end of the service life of the Bonner Bridge. Continued demand for convenient daily and emergency access across Oregon Inlet is expected. The natural channel, or gorge, through the Oregon Inlet migrates, and any replacement bridge needs to provide spans of sufficient height and width for navigation through the anticipated area of future natural channel migration, helping to reduce future dredging needs, dredging impacts, and the cost of dredging. The southern terminus of the Bonner Bridge is located north of parts of NC 12 that are frequently threatened by shoreline erosion and overwash. Placing the southern terminus of a replacement bridge at Rodanthe or implementing a long-term NC 12 maintenance project between Rodanthe and Oregon Inlet will eliminate regular maintenance of NC 12 in this part of Hatteras Island.

Chapter 2

Alternatives Considered

2.0 Alternatives Considered

Chapter 2 describes the No-Action Alternative, as well as the two Bonner Bridge replacement corridors evaluated in detail in Chapter 4 of this document. It also describes other alternatives considered, but not retained, for detailed evaluation. It explains why these other alternatives were dropped from consideration as reasonable bridge replacement options. This chapter has the following discussions, beginning in chronological order with the detailed study alternatives development process:

- The No-Action Alternative is discussed beginning on page 2-4.
- 1993 Draft Environmental Impact Statement (DEIS) Alternatives

  The alternatives examined in the November 1993 Draft for the replacement of Bonner Bridge, including the preferred replacement bridge corridor selected for implementation after public hearings in February 1994, are discussed beginning on page 2-5 and shown in that section in Figure 2-1. Alternatives assessed were:

  - Transportation Systems Management (TSM);
  - Rehabilitate Existing Bridge;
  - Ferry;
  - Tunnel;
  - East Bridge Corridor;
  - West Bridge Corridor; and
  - Original Parallel Bridge Corridor (preferred alternative in the 1993 DEIS).
- 2002 Pamlico Sound Bridge Corridor Alternatives

  Additional replacement bridge corridor alternatives studied in 2002 because of changed conditions in the project area and changed regulatory requirements are discussed beginning on page 2-34 and shown in that section in Figure 2-3. Alternatives assessed were:

  - Alternative 1a;
  - Alternative 1b (wide);
  - Alternative 1b (close);
  - Alternative 1c;
  - Alternative 2 (wide);
  - Alternative 2 (close);

- Alternative 3 (wide);
- Alternative 3 (close); and
- Alternative 4 (selected for alignment alternatives study in 2003).

- 2003 Pamlico Sound Bridge Corridor Alternatives

  Bridge alignment alternatives studied in 2003 following the identification of the Pamlico Sound Bridge Corridor as a corridor to evaluate in detail in this Final Environmental Impact Statement (FEIS) are discussed beginning on page 2-42 and shown in that section in Figure 2-4 . Two of the alternatives selected for detailed assessment in Chapter 4 were identified as a part of this study. Alternatives assessed were:

  - Alignment A **(selected for detailed study as the Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus Alternative)**;
  - Alignment B;
  - Alignment C **(selected for detailed study as the Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus Alternative)**;
  - Alignment D;
  - Alignment E; and
  - Alignment F.

- 2004 Additional Replacement Bridge Scenarios

  At the request of the Dare County Commissioners, additional replacement bridge (including long-span bridges) scenarios were evaluated in 2004 and are discussed beginning on page 2-54 and their location is shown in that section in Figure 2-7. Alternatives assessed were:

  - Multiple Cable-Stayed;
  - Single Span Cable-Stayed;
  - Suspension; and
  - Multiple Arch Bridges.

- 2005 Parallel Bridge Corridor with NC 12 Maintenance Alternatives

  Parallel Bridge Corridor with NC 12 Maintenance Alternatives studied in 2005 following the decision to add this corridor to the alternatives evaluated in detail in this FEIS are discussed beginning on page 2-58 and shown in that section in Figure 2-9a and Figure 2-9b. Three of the alternatives selected for detailed assessment in Chapter 4 were identified as a part of this study. Alternatives assessed were:

  - Nourishment **(selected as the Parallel Bridge Corridor with Nourishment Alternative for detailed study)**;

- Nourishment North/Bridge South;
- Relocate Road North (West of 2060 Shoreline)/Bridge South **(selected for detailed study as the Parallel Bridge Corridor with Road North/Bridge South Alternative)**;
- Relocate Road North (West of Ponds)/Bridge South;
- Relocate Road North (West of 2060 Shoreline)/Interim Road then Bridge South; and
- All Bridge **(selected for detailed study as the Parallel Bridge Corridor with All Bridge Alternative)**.

- 2006 Additional Parallel Bridge Corridor with NC 12 Maintenance Alternatives

  Additional Parallel Bridge Corridor with NC 12 Maintenance Alternatives studied in 2006, which added two more NC 12 Maintenance alternatives to the three selected in 2005 for detailed evaluation in Chapter 4 of this FEIS are discussed beginning on page 2-77 and are shown in Figure 2-21.

  - Phased Approach/Rodanthe Bridge **(selected for detailed study)**; and
  - Phased Approach/Rodanthe Nourishment **(selected for detailed study)**.

- 2006 Long Bridge Operations and Safety Study

  A Long Bridge Operations and Safety Study was conducted in 2006 to address questions about the safe operation of long bridges, which were raised at the November 2005 public hearing and during the review of the Supplemental Draft Environmental Impact Statement (SDEIS). These concerns dealt specifically with the proposed Pamlico Sound Bridge Corridor Alternative that includes a 17.5-mile bridge crossing of the Sound, beginning on page 2-78.

Following the descriptions of the detailed study alternatives development process, Chapter 2 concludes with descriptions of the detailed study alternatives presented in the following discussions:

- Pamlico Sound Bridge Corridor Detailed Study Alternatives

  Descriptions of the Pamlico Sound Bridge Corridor alternatives, as evaluated in detail in Chapter 4 of this FEIS are discussed beginning on page 2-81.

- Parallel Bridge Corridor with NC 12 Maintenance Detailed Study Alternatives

  A description of the Parallel Bridge Corridor with NC 12 Maintenance alternatives, as evaluated in detail in Chapter 4 of this FEIS, are discussed beginning on page 2-93.

- Demolition and Removal of Bonner Bridge

  The process for the demolition and removal of the existing Bonner Bridge is discussed beginning on page 2-130.

- Costs and Funding

  Cost estimates and funding sources for both the Pamlico Sound Bridge Corridor and Parallel Bridge Corridor alternatives (including the Preferred Alternative) are discussed beginning on page 2-132.

- Environmental Protection During Construction and Demolition

  General environmental protection strategies that would be used during both project construction and Bonner Bridge demolition are discussed beginning on page 2-144.

- Permits and Approvals

  The permits and approvals needed for the replacement bridge from various regulatory agencies are described beginning on page 2-146.

Finally, the identification and rationale for selection of the Preferred Alternative is discussed beginning on page 2-148.

2.1 No-Action Alternative

The No-Action Alternative assumes that Bonner Bridge would be demolished at the end of its practical service life and not replaced. A small-scale ferry service adequate to meet the fundamental travel needs of Hatteras Island residents would be provided across Oregon Inlet. Access to the mainland also would remain via existing ferry routes from the mainland (i.e., Cedar Island and Swan Quarter) to Ocracoke Island and then the existing ferry route from Ocracoke Island to Hatteras Island. The inclusion of a small-scale ferry service in the No-Action Alternative acknowledges that Bonner Bridge cannot remain in place indefinitely because it is at the end of its practical service life. North Carolina Department of Transportation (NCDOT) is obligated to provide transportation access of some sort to all properties in the state.

The current ferry service between Hatteras Island and the mainland via Ocracoke Island offers space for approximately 400 to 450 automobile crossings per day during the summer. The ferry across the Hatteras Inlet from Hatteras Island to Ocracoke Island carries as many as 3,500 vehicles per day in the summer. The sailing time for these services is three hours and five minutes from Hatteras Island to the mainland via either ferry route, not including time to change ferries on Ocracoke Island. (Personal communication, October 10, 2003, Jesse Vinson, NCDOT Ferry Division.)

Specifics related to a new small-scale ferry service from Bodie Island to Hatteras Island would have been developed if following public review of the SDEIS and the Supplement to the Supplemental Draft Environmental Impact Statement (SSDEIS), this alternative had been selected as the Preferred Alternative. The environmental impact assessment process requires that the No-Action Alternative be presented for review.

The level of service of the small-scale ferry service implemented under a No-Action Alternative likely would be similar to the service between Hatteras Island and the mainland via Ocracoke Island described above. The emergency ferry service across Oregon Inlet—provided from November 1990 to February 1991 after Bonner Bridge was damaged by a dredge and temporarily closed—had a maximum transport capacity of approximately 6,000 vehicles per week or 900

vehicles per day. The sailing time for that service was 80 minutes, including loading and unloading.

Nine hundred vehicles per day is far less than both the existing demand and the expected 2025 demand presented in Table 1-2, which shows an average annual daily traffic of 9,600 vehicles per day and peak traffic of 25,200 vehicles per day in 2025. The No-Action Alternative would not meet the project's purpose and need as presented in Chapter 1.

2.2 1993 Draft Environmental Impact Statement Alternatives

The alternatives considered in the November 1993 DEIS, as well as the Preferred Alternative selected after the February 23 and 24, 1994 public hearings were developed based on a feasibility study that was completed in 1991 to examine possible Bonner Bridge replacement alternatives. The study's findings are documented in *Feasibility Study for the Replacement of the Herbert C. Bonner Bridge on NC 12 over Oregon Inlet* (NCDOT, April 1991). The range of alternatives examined in the study was based upon agency input in response to:

- A May 1990 feasibility study scoping letter;
- Public input from a July 19, 1990, Citizens Informational Workshop; and
- Engineering, environmental, and coastal studies documented in the 1991 feasibility study report.

The alternatives and preliminary feasibility study findings were presented for public review at Citizens Informational Workshops on February 19 and 20, 1991. Selection of the Preferred Alternative presented in the 1993 DEIS was based on:

- Workshop comments;
- Feasibility study findings;
- Agency responses to the May 1991 distribution of a scoping letter and copies of the feasibility study report; and
- Input from a May 29, 1991, scoping meeting held for local, state, and federal environmental resource and regulatory agencies.

Refinements were made to the 1993 DEIS Preferred Alternative based on agency responses to the November 1993 distribution of the DEIS, public hearings held in February 1994, and a bridge type study completed in 1995. Because beach erosion increased problems with ocean overwash along NC 12 south of Bonner Bridge, the Preferred Alternative evaluated in the 1993 DEIS (i.e., the Parallel Bridge Corridor without a NC 12 maintenance component) is no longer considered a viable replacement alternative for Bonner Bridge. The description of 1991 to 1993 findings contained in this section is presented to inform the reader of past study results. Study results are updated, as appropriate, to account for current alternative selection criteria.

2.2.1 Basic Assumptions Used in 1991 and 1993

The alternatives considered in the 1991 feasibility study report and the 1993 DEIS were developed based on several basic assumptions regarding:

- The implementation of the then-proposed US Army Corps of Engineers' (USACE) jetty project;
- The future disposition of the terminal groin at the northern end of Hatteras Island;
- Future coastal conditions; and
- Connection of a new crossing to NC 12.

These assumptions are described below.

2.2.1.1 US Army Corps of Engineers' Proposed Jetty Project

The construction of jetties, both to stabilize Oregon Inlet and to partially stabilize the adjacent barrier island shoreline, was being considered when the feasibility study report and DEIS were prepared. Originally, these jetties were to be built shortly after the completion of Bonner Bridge in the 1960s. The jetty project, however, was delayed many times, and it is no longer under consideration.

In light of the uncertainty of the jetty project in 1991 and 1993, all of the alternatives considered at that time assumed that the USACE's proposed jetties would not be built. The alternatives would not have interfered with jetty construction or would not have been incompatible with the changes that jetties would have caused in Oregon Inlet.

2.2.1.2 Future Disposition of the Terminal Groin

It was assumed that the terminal groin at the northern tip of Hatteras Island, which was built by the NCDOT in 1989 and 1990, would remain in place.

2.2.1.3 Coastal Conditions

Hatteras Island and Bodie Island continually change because of natural and manmade events. All of the alternatives examined in 1991 and 1993 assumed that:

- The USACE did not maintain the navigation channel through Oregon Inlet via hopper dredging with offshore dredged sand disposal, but instead either disposed of sand on Hatteras Island beaches via a hydraulic pipeline dredge or maintained natural sand bypassing of Oregon Inlet.
- The terminal groin was not flanked by beach erosion south of the groin, and it would continue to secure the northern tip of Hatteras Island.
- Hatteras Island beaches would continue to erode. This erosion would result in approximately 1.4 miles (2.2 kilometers) of NC 12, at its existing location south of Bonner Bridge, being lost by year 2050. Either NC 12 would be relocated further west as needed to connect to any new bridge terminus on Hatteras Island, or the new bridge terminus would be modified before 2050 to connect to a longer bridge west of Hatteras Island.

2.2.1.4 NC 12 Connection

During the 1991 feasibility study (in which the relocation of NC 12 on or west of Hatteras Island was not a part of the bridge replacement alternatives), it was decided that a replacement crossing of the Oregon Inlet should transition back to the existing NC 12 alignment as quickly as possible at each end of the crossing. This decision was made for the following reasons:

- The decision was compatible with the coastal conditions assumptions described in Section 2.2.1.3.
- A new crossing, connecting to existing NC 12 on Hatteras Island, could be designed such that later it could be connected to a range of potential future NC 12 locations.
- Better decisions related to the disposition of NC 12 near the Bonner Bridge could be made if it were studied as a part of a comprehensive study of NC 12 rather than as a part of the Bonner Bridge replacement study. Such a study was underway in consultation with the USACE, but is currently (2008) unfunded by the US Congress. The Parallel Bridge Corridor with NC 12 Maintenance Alternatives assessed in this FEIS address long-term (through 2060) NC 12 maintenance as far south as the community of Rodanthe.
- Placement of a connection between a new crossing and NC 12 at any other location would result in greater natural resource impacts.
- The need to replace Bonner Bridge was urgent and is even more urgent presently. In 1991, it seemed unreasonable to tie the long-term need of NC 12 with the short-term need of replacing Bonner Bridge.
- The purpose of the project—as included in the NCDOT's *State Transportation Improvement Program* (TIP) at the time—was to replace a structurally deficient bridge.

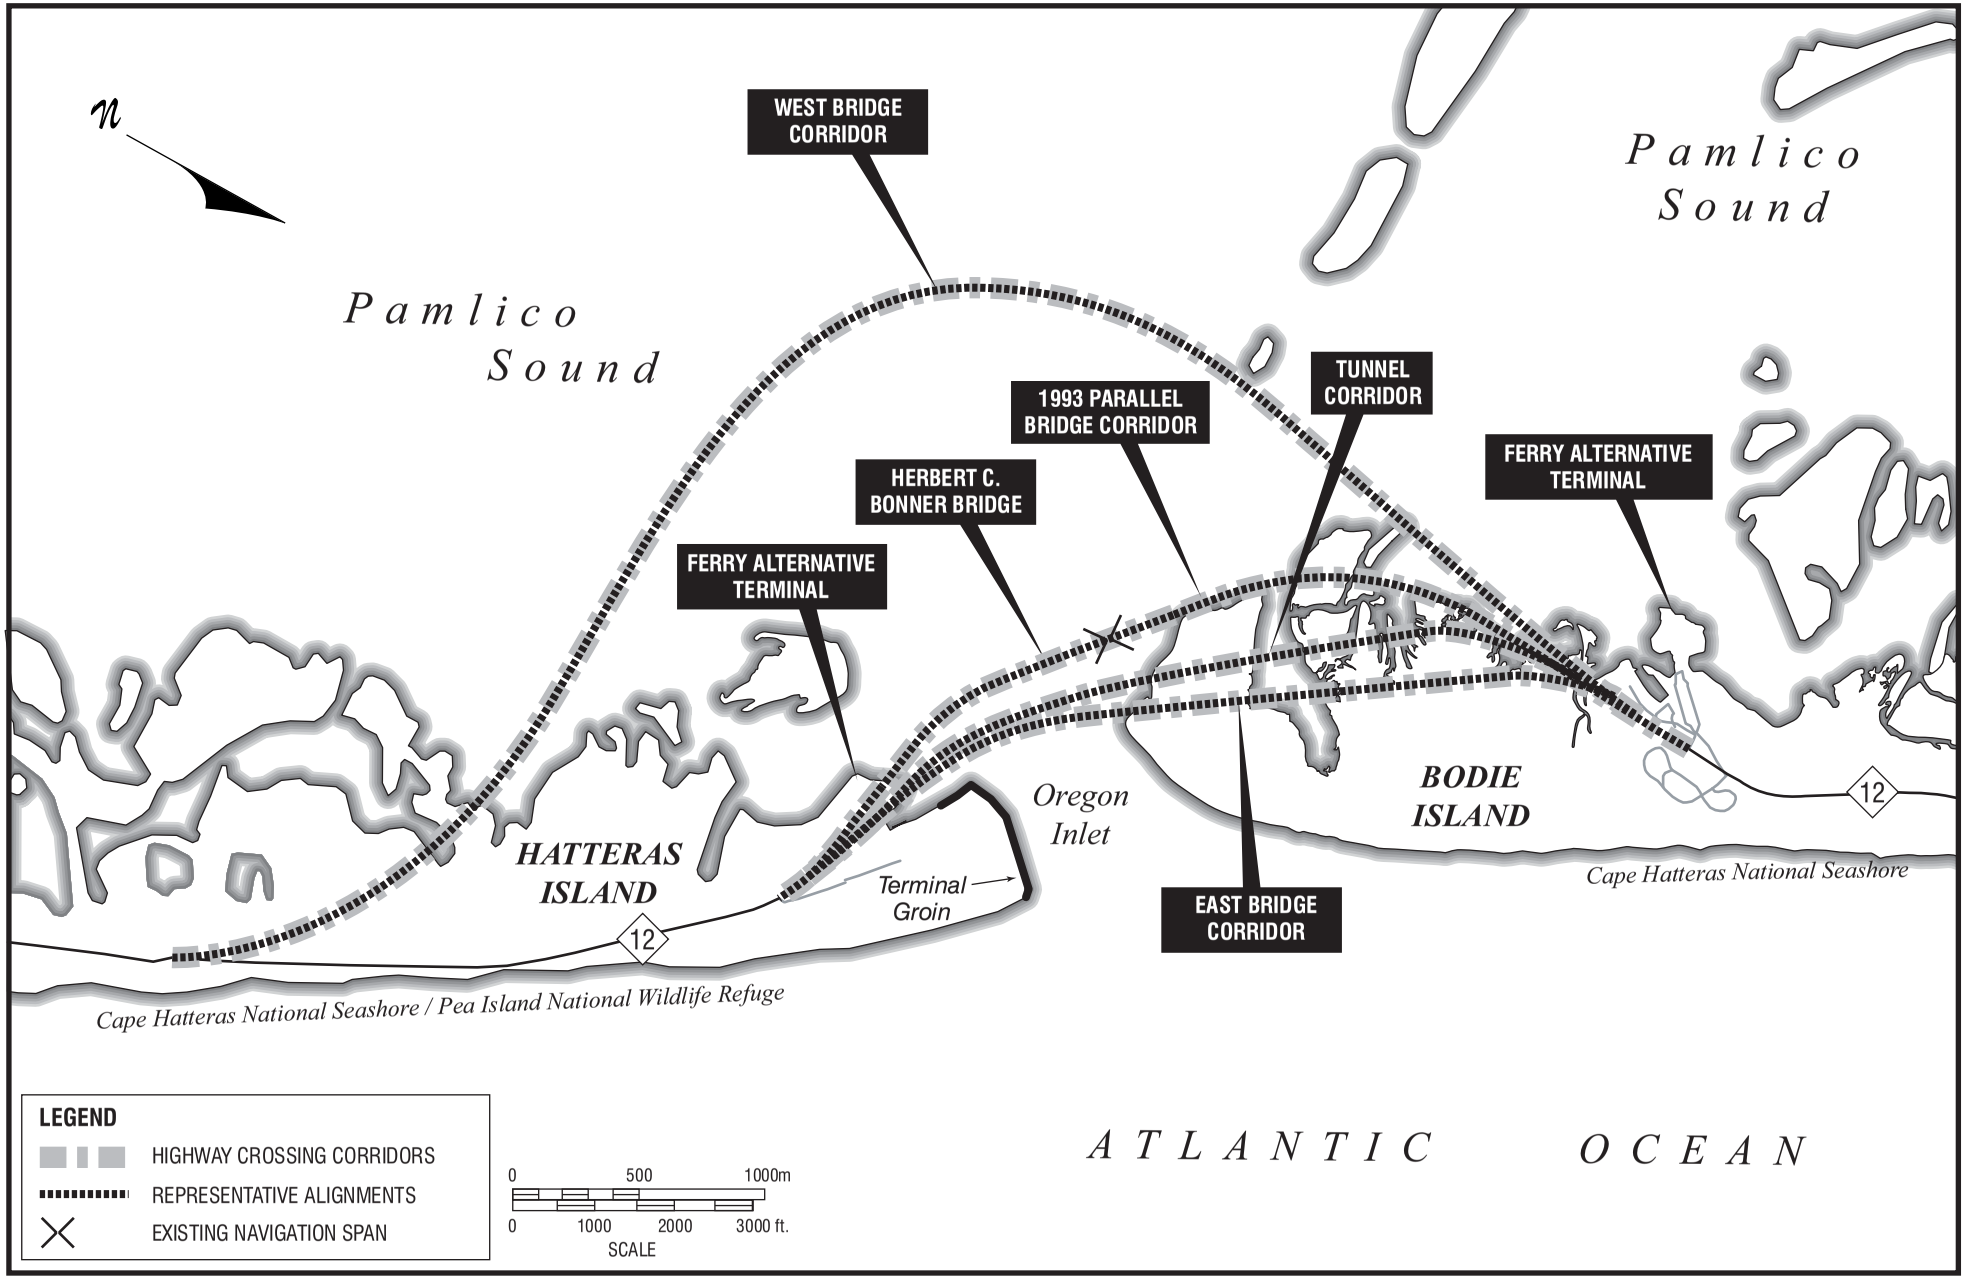
2.2.2 Summary of Alternatives Analysis Findings

Sections 0 through 2.2.9 describe the alternatives that were developed in 1991 and discussed in the 1993 DEIS, including the then-Preferred Alternative (1993 Parallel Bridge Corridor) as refined after the 1994 public hearings and 1995 bridge type study. The alternatives to the then-Preferred Alternative evaluated during the 1991 feasibility study found to not warrant detailed study in the 1993 DEIS were the: TSM Alternative, Rehabilitate the Existing Bridge Alternative, Ferry Alternative, Tunnel Alternative, East Bridge Corridor, and West Bridge Corridor. Given shoreline erosion trends since 1994, with the exception of the Ferry Alternative, none of these alternatives would eliminate the need to maintain portions of NC 12 that are threatened by shoreline erosion and overwash. In addition, these alternatives were found not to warrant detailed study for the following reasons:

- TSM Alternative. This alternative was not studied in detail in 1993 since the purpose of the proposed project is not to augment an existing system because of over-utilization but to replace a structure nearing the end of its service life.
- Rehabilitate the Existing Bridge Alternative. The problems with Bonner Bridge have proven to be difficult, expensive to resolve, and increasing in degree of severity. The bridge suffers extensive corrosion of reinforcing steel, major spalling of concrete (pieces of concrete breaking away from the surface of a steel reinforced concrete structure), extensive pile scour, insufficient ship impact strength, and has a narrow navigation span zone. It would leave the amount of dredging required to maintain the Oregon Inlet navigation channel unchanged.

- Ferry Alternative. This alternative would decrease the present level of traffic service across Oregon Inlet and increase emergency evacuation time. Lost accessibility would have a substantial impact on the economies of Hatteras Island and Dare County. This alternative also would be one of the most damaging to the natural environment because of the dredging required for navigation. Approximately 59 acres (23.6 hectares) of wetlands would be permanently used by ferry operating facilities on Bodie and Hatteras islands.

- Tunnel Alternative. This alternative would be substantially more expensive than building a new bridge and one of the most damaging to the natural environment. Excavation of Oregon Inlet's bottom would be required during the construction phase, which would remove benthos in a total area of approximately 150 acres (60 hectares). In addition, approximately 33.3 acres (13.3 hectares) of wetlands would be filled.



- East Bridge Corridor. This corridor would be shorter than the other bridge corridors. However, it would result in greater impacts to biotic communities and wildlife habitat on Bodie Island. In addition, cost savings resulting from a shorter structure would be offset by costs related to the risks introduced by construction in an area of greater wave activity, faster currents during storm surges, and less protected from storms.

- West Bridge Corridor. Compared to the then-preferred 1993 Parallel Bridge Corridor, this corridor would be a substantially longer and more expensive structure. It also would result in connections to existing NC 12 that would cross valuable habitat within the Pea Island National Wildlife Refuge (Refuge). This corridor is similar to Corridor Alternative 1, which was examined and dropped from consideration in the 2002 corridor alternatives studies described in Section 2.3.

The 1993 Parallel Bridge Corridor was assessed in the 1993 DEIS as the preferred corridor and was selected by the NCDOT as the Preferred Alternative for implementation after public hearings in February 1994. It was further refined after a 1995 bridge type study. Because beach erosion has increased problems with ocean overwash along NC 12 south of Bonner Bridge, the Preferred Alternative identified in 1993 is now being considered in conjunction with a long-term plan or strategy for NC 12 maintenance through the Refuge (see Sections 2.6 and 2.7).

Sections 2.2.3 to 2.2.9 review the alternatives identified above and describe more specifically the reasons they were dropped from further consideration. The TSM and West Bridge Corridor, dropped from further study early in the feasibility study process, are discussed only in general terms. During the feasibility study, the Ferry Alternative, the Tunnel Alternative, the East Bridge Corridor, and the 1993 Parallel Bridge Corridor (the then-Preferred Alternative) were examined closely. The paragraphs describing the 1993 Parallel Bridge Corridor reflect the project as refined after the 1994 public hearing and the 1995 bridge type study.

The locations of the 1993 Parallel Bridge, Ferry, Tunnel, East Bridge, and West Bridge Alternatives are shown in Figure 2-1. Table 2-1, Table 2-2, and Table 2-3 compare the 1993 Parallel Bridge, Ferry, Tunnel, and East Bridge Alternatives from the perspectives of transportation, coastal engineering, and environmental tradeoffs, respectively. In addition, the expense and impact of the on-going maintenance of NC 12, including beach nourishment, dune maintenance, and repairs required because of highway overwash during storms would continue south of the Hatteras Island terminus of these alternatives until a long-term solution to NC 12 maintenance (between the northern end of Hatteras Island and Rodanthe) could be implemented.

1993 CROSSING ALTERNATIVES

Figure 2-1

Table 2-1. Transportation Tradeoffs for 1993 Crossing Alternatives

Evaluation Factors	1993 Parallel Bridge Corridor (1993 Preferred Alternative)	Ferry	Tunnel	East Bridge Corridor
Inlet Navigation	Navigation spans with a minimum 200-ft. (61 m) horizontal and a 75-ft. (22.9 m) vertical clearance would meet inlet navigation needs. Navigation spans across Oregon Inlet would mean the channel could be allowed to drift with the inlet's gorge, making it easier to keep clear.	Ferry service would increase inlet traffic and operate across and conflict with existing inlet traffic.	The tunnel should have no effect on, or be affected, by inlet navigation since it would be under the Oregon Inlet floor.	Navigation spans with a minimum 200-ft. (61 m) horizontal and 75-ft. (22.9 m) vertical clearances would meet inlet navigation needs. Navigation spans across Oregon Inlet would mean the channel could be allowed to drift with the inlet's gorge, making it easier to keep clear.
Traffic Service	An acceptable peak hour level of service would be provided on NC 12 through 2025 except on summer weekends when a four-lane NC 12 would be needed. Roadway width of 36 ft. (11 m) would allow a wider recovery area during accidents and around obstructions.	Ferry service could not meet existing or future traffic demand.	An acceptable peak hour level of service would be provided on NC 12 through 2025 except on summer weekends when a four-lane NC 12 would be needed.	An acceptable peak hour level of service would be provided on NC 12 through 2025 except on summer weekends when a four-lane NC 12 would be needed. Roadway width of 36 ft. (11 m) would allow a wider recovery area during accidents and around obstructions.
Emergency Evacuation	The 36-ft. (11 m) cross-section would permit operation of three lanes (two leaving the island) in emergencies; this could facilitate evacuation clearance.	Limited transport capacity would dramatically increase the evacuation clearance time from Hatteras and Ocracoke islands.	The existing capacity for emergency evacuation would remain.	The 36-ft. (11 m) cross-section would permit operation of three lanes (two leaving the island) in emergencies, which could facilitate evacuation clearance.
Bicycles & Pedestrians	The 6-ft. (1.8-m) bridge shoulders would be safer for bicycle and pedestrian traffic than the existing 2-ft. (0.6-m) shoulders.	Bicyclists and pedestrians could use the ferry service.	The tunnel environment would not be suitable for bicyclists and pedestrians.	The 6-ft. (1.8-m) bridge shoulders would be safer for bicycle and pedestrian traffic than the existing 2-ft. (0.6-m) shoulders.

Table 2-2. Coastal Engineering Tradeoffs for 1993 Crossing Alternatives

Evaluation Factors	1993 Parallel Bridge Corridor (1993 Preferred Alternative)	Ferry	Tunnel	East Bridge Corridor
Inlet Migration	Provided that hopper dredging does not occur or is mitigated and the terminal groin is maintained, Oregon Inlet's migration at Hatteras Island should cease, and abutments would not be threatened during bridge life expectancy.	Ferry service would not be affected by inlet migration; ferry landings could be located so that they would not be endangered by erosion.	The portals of the Tunnel Alternative would not be threatened by erosion, provided that hopper dredging does not occur (or is mitigated) and the groin is maintained.	Provided that hopper dredging does not occur or is mitigated and the terminal groin is maintained, Oregon Inlet migration at Hatteras Island should cease and abutments would not be threatened during bridge life expectancy.
Inlet Gorge	If the gorge moves south, vessels would be forced to make a sharp, cross-current turn to complete the transition from the island-parallel channel between Wanchese and the Oregon Inlet channel. Also, Oregon Inlet's channel is more variable along this alignment, and the proper navigation span to use might change frequently.	The Ferry Alternative would not be affected by channel changes. It would be difficult, however, to maintain the required ferry channel in a cross-current direction across Oregon Inlet. Continuous maintenance dredging of the ferry channel probably would be needed.	Channel changes would not affect the Tunnel Alternative.	This alignment would provide a less severe angle in the channel at the bridge if the gorge moves south. Also, Oregon Inlet's gorge is not as variable in this location; thus, the navigation span would not change as often as with the west alternative.
Flexibility to Meet Future Navigation Demand	Navigation spans would be provided throughout the range of possible inlet gorge locations. This design feature would allow flexibility in the number and sizes of vessels using Oregon Inlet.	Other than frequent ferry crossings of the navigation channels, future navigation demand should not be influenced by the ferry service.	The Tunnel Alternative would not affect future navigation demands.	Navigation spans would be provided throughout the range of possible inlet gorge locations. This design feature would allow flexibility in the number and sizes of vessels using Oregon Inlet.
Dredging Requirements	The bridge would provide the opportunity to scale back dredging operations in Oregon Inlet. The placement of the navigation spans across the entire inlet would permit greater acceptable movement of the navigation channel.	Dredging would be necessary to maintain the depth and horizontal clearances for the vessel passages to and from the ferry terminals. This activity would be in addition to that for the maintenance of Oregon Inlet's channel. The USACE believes the ferry channel in the Oregon Inlet area would have stability problems.	Construction of the tunnel would require extensive excavation during construction. Beyond that, however, the movement of Oregon Inlet's gorge would place no restrictions on maintaining a navigation channel through Oregon Inlet, provided the inlet remains between the portals.	The alternative could provide the opportunity to scale back dredging operations in Oregon Inlet. The placement of the navigation spans across the entire inlet would permit greater acceptable movement of the navigation channel.
Shoreline Erosion	Anticipated natural shoreline erosion would threaten up to 1.4 miles (2.2 km) of NC 12 at the north end of Hatteras Island by 2050. NC 12 would need to be relocated.	Anticipated natural shoreline erosion on Hatteras Island would make it difficult to locate a southern ferry terminal north of Rodanthe; this would necessitate a ferry channel approximately 18 miles (29.0 kilometers) long.	Anticipated natural shoreline erosion would threaten up to 1.4 miles (2.2 km) of NC 12 at the north end of Hatteras Island by 2050. NC 12 would need to be relocated.	Anticipated natural shoreline erosion would threaten up to 1.4 miles (2.2 km) of NC 12 at the north end of Hatteras Island by 2050. NC 12 would need to be relocated.

Table 2-3. Environmental Tradeoffs for 1993 Crossing Alternatives

Evaluation Factors	1993 Parallel Bridge Corridor (1993 Preferred Alternative)	Ferry	Tunnel	East Bridge Corridor
Community	This alternative would have no impact on land use and socioeconomic factors since the same level of traffic service would be maintained and community services would not be disrupted.	This alternative would severely limit the movement of goods and services from the mainland to Hatteras Island. Residents and visitors to Hatteras Island rely on off-island community services, such as hospitals, solid waste disposal, and electrical power.	This alternative would have no impacts on land use and socioeconomic factors since the same level of traffic service would be maintained and community services would not be disrupted.	This alternative would have no impacts on land use and socioeconomic factors since the same level of traffic service would be maintained and community services would not be disrupted.
Visual	Views from the (former) US Coast Guard Station on Hatteras Island, at the marina, and on the Bodie Island spit would be virtually unchanged.	Bonner Bridge would be removed from view and ferry terminals introduced at the Oregon Inlet Marina and in the Rodanthe area.	Bonner Bridge would be removed from view. A trestle approach structure would be built on Bodie Island. The wall and ventilation building around the portals would be an intrusive feature not in keeping with the island's character.	The new bridge would be closer to the historic (former) US Coast Guard Station. It would dominate views to the west on the Bodie Island spit. Views from the marina would be virtually unchanged. Longer spans would present a less cluttered profile than Bonner Bridge.
Air	Since this alternative would not result in increased traffic levels over the existing situation, no impact would occur.	Since this option would reduce the vehicular traffic across Oregon Inlet, it would have no impact on air quality.	Since this alternative would not result in increased traffic levels over the existing situation, no impact would occur.	Since this alternative would not result in increased traffic levels over the existing situation, no impact would occur.
Noise	Because of its location, this bridge corridor should have minimal impact on noise in the Oregon Inlet area.	Since traffic is the dominant source of noise in this area, the ferry service, with a reduction in traffic level, would have a minimal negative impact on the noise level.	Because of its location, the tunnel should have a minimal impact on noise in the Oregon Inlet area.	Noise levels would increase at the Bodie Island spit.
Cultural Resources				
Historic Architectural Resources	No land within the (former) US Coast Guard Station National Register site would be used. See Visual comparison above.			
Human Habitation Related Archaeological Resources	The Outer Banks' dynamic environment is not conducive to good archaeological preservation. No impacts are expected.			
Shipwreck Archaeological Resources	There are no known shipwreck sites in the corridor; however, there is a history of shipwrecks at Oregon Inlet.			

Table 2-3 (continued). Environmental Tradeoffs for 1993 Crossing Alternatives

Evaluation Factors	1993 Parallel Bridge Corridor (1993 Preferred Alternative)	Ferry	Tunnel	East Bridge Corridor
Parks	The north and south ends of this alternative would be within the Cape Hatteras National Seashore. The south end also would be in the Pea Island National Wildlife Refuge.	This alternative could alter access opportunities to the Seashore and the Refuge. One terminal and the landing areas would be constructed in the Cape Hatteras National Seashore.	The north and south ends of this alternative would be within the Cape Hatteras National Seashore. The south end also would be in the Pea Island National Wildlife Refuge.	The north and south ends of this alternative would be within the Cape Hatteras National Seashore. The south end also would be in the Pea Island National Wildlife Refuge.
Natural Systems				
Biotic Communities	There would be slight impacts on biotic communities since the corridor crosses substantial acreage of needlerush pockets, smooth cordgrass stands, and open waters. Slight impacts would occur in maritime shrub thickets and to fisheries. Minimal impacts would accrue to birds, small mammals, and amphibians from loss of habitats. Moderate impacts to benthos.	Dredging in open waters would affect benthos and fisheries. Permanent use of biotic communities for the operating facilities associated with the landings on Hatteras and Bodie islands would be substantial.	The tunnel would cause substantial impacts on biotic communities on Bodie Island as it would necessitate the removal of large stands of needlerush pockets and smooth cordgrass stands, which in turn would cause slight to moderate impacts on birds, small mammals, reptiles, and amphibians resulting from loss of habitat. Substantial impacts on benthos and moderate impacts on fisheries would result from a loss of critical habitat because of construction dredging.	This alignment would cause moderate impacts on biotic communities as it crosses substantial acreage of high marsh, maritime shrub thickets, needlerush pockets, smooth cordgrass stands, and open water areas. Slight impacts on birds, small mammals, reptiles, amphibians, benthos, and fisheries as a result of loss of habitats.
Oregon Inlet Birds	Slight impacts on wintering waterfowl and migrating shorebirds could occur because of habitat loss associated with temporary dredge canals and placement of piers.	Moderate impacts would be expected on wintering waterfowl and migrating shorebirds because of loss of habitat caused by dredging basins and navigational channels and permanent habitat loss.	Slight to moderate impacts would be expected on wintering waterfowl and migrating shorebirds because of permanent habitat loss.	Moderate impacts on wintering waterfowl and migrating shorebirds could occur because habitat loss associated with temporary dredge canals and placement of piers.

Table 2-3 (continued). Environmental Tradeoffs for 1993 Crossing Alternatives

Evaluation Factors	1993 Parallel Bridge Corridor (1993 Preferred Alternative)	Ferry	Tunnel	East Bridge Corridor
Surface Water Quality	Slight temporary impact could result from increased turbidity during construction of temporary dredge canals and the placement of piers.	Moderate impacts would result from increased turbidity during initial dredging and maintenance of basins and navigation channels.	Moderate impacts could result from increased turbidity during excavation, construction, and maintenance. Elevated levels of metals also could occur during tunnel construction and maintenance.	Slight temporary impact could result from increased turbidity during construction of temporary dredge canals and the placement of piers.
Protected Species	By disturbing resting and feeding activities, construction activities could cause temporary minimal impacts on several federally protected birds that occasionally utilize the area. No impacts are anticipated for federally protected sea turtles. Some piping plover habitat would be used during construction but it is not likely to affect the piping plover adversely.	Slight impacts on several federally protected birds that occasionally use the area could result from dredge disposal on potential nesting and resting sites.	Slight impacts on several federally protected birds that occasionally use the area could result from construction activities and permanent loss of habitat. No impacts would be expected on federally protected sea turtles. Some permanent loss of habitat potentially used by nesting and feeding piping plovers.	Construction activities could cause temporary minimal impacts on several federally protected birds that occasionally use the area: piping plover, Arctic peregrine falcon, bald eagle, and roseate tern. No impacts would be anticipated for federally protected sea turtles. Substantial piping plover habitat would be used during construction.

NOTE: Following are relative quantifications of the impact level descriptors used in Table 2-3:

No impact (not measurable)

Minimal impact (barely measurable)

Slight impact (measurable)

Moderate impact (localized loss)

Substantial impact (complete localized loss)

2.2.3 Transportation Systems Management (TSM) Alternative

A Transportation Systems Management Alternative is one that seeks to maximize the efficiency of the present system so that it can carry greater traffic volumes at an acceptable level of service. Typical TSM alternatives include fringe parking, ride-sharing, high-occupancy vehicle lanes on existing roadways, and traffic signal timing optimization. This alternative generally is found to be relevant only for major projects proposed in urbanized areas with populations greater than 200,000.

A TSM alternative was not assessed in detail since the purpose of the proposed project is not to augment an existing system because of over-utilization but to replace a structure nearing the end of its service life.

2.2.4 Rehabilitation of Existing Bridge

This alternative was not assessed in detail because of Bonner Bridge's poor condition, its insufficient ship impact strength, and its narrow navigation span zone.

As described in Chapter 1, Bonner Bridge has required continual maintenance since its construction. There are three major chronic problems:

1. Deterioration of the bridge through extensive corrosion of the reinforcing steel and major spalling of concrete on the supporting structures;

2. Scour to a depth equal to, or greater than, the critical depth for the piles supporting the bridge; and

3. The periodic need for vessels to use spans other than the primary span for navigation because of encroachment on the primary span by the Bodie Island spit.

These problems were, and continue to be, mitigated temporarily, but large maintenance and repair expenditures are expected to continue on a regular basis unless the bridge is replaced. The narrow navigation span zone of Bonner Bridge would remain with this alternative and no benefits from decreased dredging would occur. Finally, the Bonner Bridge was not designed to withstand the impact of a dredge, a vessel that regularly operates near the bridge. A hopper dredge vessel demolished several spans of Bonner Bridge in late 1990.

2.2.5 1993 Parallel Bridge Corridor (1993 DEIS Preferred Alternative)

Construction of a new bridge in a corridor parallel to Bonner Bridge was the preferred alternative in the 1993 DEIS, and that alternative was formally selected as the preferred alternative after public hearings in 1994. For evaluating the impact of a new bridge in the 1993 Parallel Bridge Corridor, a representative project was used in the DEIS. The use of the term “representative” reflects that the project as defined for environmental studies could be refined or slightly altered during final design, although the impacts would not be substantially changed. A refined representative project was in fact developed as a part of a bridge type study completed in 1995. The type study is described in *Bonner Bridge Type Study* (Parsons Brinckerhoff Quade & Douglas, Inc., March 1995). This refined project is described in this section. This description reflects the characteristics of the Parallel Bridge Corridor that when compared with other Oregon

Inlet crossing alternatives in 1993 and 1994, yielded the decision that a replacement bridge immediately west of Bonner Bridge is the preferred approach.

Sections 2.2.5.1 through 2.2.5.5 describe the 1993 Parallel Bridge Corridor's representative horizontal alignment, design characteristics, environmental impact potential, costs, and construction procedures.

The 1993 Parallel Bridge Corridor is incorporated, with variations in the location of its south terminus, into the several Parallel Bridge Corridor detailed study alternative described in Section 2.10 and evaluated in detail in Chapter 4.

2.2.5.1 Representative Horizontal Alignment

The representative alignment used in the 1993 Parallel Bridge Corridor would range from 60 feet (18.3 meters) to 500 feet (152.4 meters) west of Bonner Bridge; the alignment is illustrated in Figure 2-1. The representative alignment would have the following bridge lengths:

Southern Approach	800 feet (243.8 meters)
Main Bridge	9,987 feet (3,043.9 meters)
Northern Approach	3,730 feet (1,136.8 meters)
TOTAL LENGTH	14,517 feet (4,424.6 meters)

Approach roadway on fill at each end of the bridge structure would be approximately 1,450 feet (441.9 meters) long on Hatteras Island and 2,850 feet (868.6 meters) long on Bodie Island, resulting in a total project length of approximately 18,817 feet (5,735 meters).

2.2.5.2 Design Characteristics

The design criteria developed for the replacement structure in the 1993 Parallel Bridge Corridor assumed a bridge with two 12-foot (3.6-meter) lanes and 6-foot (1.8-meter) shoulders on each side, a 36-foot (11-meter) clear roadway width. The total outside width of the bridge was assumed to be 38.6 feet (11.8 meters); the additional 2.6 feet (0.8 meter) would accommodate the bridge rails. The approach roadway (on fill) was assumed to have 8-foot (2.4-meter) shoulders (4-foot [1.2-meter] paved) and provide 8 feet (2.4 meters) of clearance from the edge of the travel lane to the face of the guard rail.

The shoulders would accommodate bicyclists and pedestrians more safely than the existing 2 feet (0.6 meters) of clearance and allow room for movement around stranded vehicles and accidents. A bicycle-safe bridge rail would be utilized. The 36-foot (11-meter) clear roadway width on the bridge could allow for the temporary emergency designation of three lanes during evacuations, with two lanes of traffic moving off the island.

Scour is a characteristic result of the dynamic nature of the Oregon Inlet that has the potential to threaten crossing structures. The new bridge would include adequate 500-year hurricane scour protection depths. Multiple navigational spans over about 5,000 feet (1,524 meters) of the bridge length with a vertical clearance of 75 feet (22.9 meters) were assumed. A minimum horizontal clearance of 200 feet (61 meters) was assumed for each navigation span. A hopper dredge, the heaviest vessel to operate in Oregon Inlet, was selected during the 1995 bridge type study as the

design vessel for ship impact. In other words, the foundations of the new bridge would need to withstand the impact of this vessel.

The geometric features for a bridge in this corridor could be designed such that extension of the bridge in association with a future relocation of NC 12 could be accommodated.

For the main bridge superstructure, long-span precast concrete segmental box girders built using the balanced cantilever construction method were planned. A box girder is a concrete girder whose cross-section is shaped like a box. Based on the scour and ship impact criteria, the foundations required in this corridor would need to be both deep and substantial in construction. Multiple large piles would be required. A footing would be cast just above the waterline on the cylinder piles. A precast segmental box column would be placed on the footing to support the superstructure.

2.2.5.3 Environmental Impact Potential

The environmental impact potential of the 1993 Parallel Bridge Corridor is summarized in Table 2-3. Key environmental considerations are described below.

Community

A bridge in this corridor would be compatible with the *Dare County Land Use Plan* and zoning, the *Coastal Zone Management Plan*, and National Park Service (NPS) plans. No unanticipated growth would be generated with the bridge replacement in this corridor, either in terms of an increased rate of development or an increased intensity of development. The Dare County plan supports new transportation projects, and the project is compatible with the "conservation" area objectives applied by that plan to the project area. Through its compliance with the local land use plan, the project would be consistent with the *Coastal Zone Management Plan*. The project is compatible with the NPS's desire of managing the Cape Hatteras National Seashore (Seashore) in ways "that support the natural processes of barrier island dynamics..." (NPS, 1991).

The social characteristics of the project area would not change with this corridor. Accessibility of Hatteras Island, the Seashore, and the Refuge would not change for area residents, tourists, workers, and off-island goods and services. The 1993 Parallel Bridge Corridor would not adversely affect community services.

The visual character of the Oregon Inlet area would not be affected by a bridge in this corridor. The scale and dominance of the replacement structure in relation to other Oregon Inlet visual elements would not differ substantially from those of Bonner Bridge.

Cultural Resources and Parks

A bridge in this corridor would not affect historic resources or change the accessibility to area resources. No shipwrecks or other archaeological sites are in the area of potential effect for this alternative.

The project would be within the Seashore on both sides of Oregon Inlet. On Hatteras Island, the project also would be within the Refuge. A bridge in this corridor would maintain roadway access to the Hatteras Island portions of the Seashore and to the Refuge. The catwalks on Bonner Bridge used for fishing likely would not be replaced for the reasons presented in Section 2.10.1.2, under "Access to Recreation Opportunities." The primary impact on the Seashore and Refuge would be on natural systems, as described later in this section.

Coastal Conditions

The project would have a negligible effect on natural inlet migration, profile, and gorge alignment. The bridge design proposed in this corridor would make navigation channel dredging operations easier to undertake and could reduce the frequency and size of dredging operations compared to what is required today.

Erosion of the Hatteras Island shoreline has continued since the 1993 studies for this alternative. Shoreline erosion and ocean overwash regularly threaten to sever segments of the NC 12 roadway for several miles south of the southern terminus of this corridor. As such, there would remain an ongoing risk of NC 12 closure and periodic temporary loss of access unless a long-term plan or strategy for minimizing this risk was implemented.

The terminal groin would need to be retained with this alternative.

Natural Systems

The area of biotic communities and wetlands affected by a bridge in this corridor would be approximately 41.8 acres (16.7 hectares):

- Permanent (fill or foundation placement)

Section 404 wetlands including 0.8 acre (0.32 hectare) of Coastal Area Management Act (CAMA) wetlands	3.5 acres	(1.4 hectares)
Aquatic bottom (pile placement only, no fill)	2.8 acres	(1.1 hectares)
Uplands (excluding man-dominated areas)	0.2 acre	(0.08 hectare)
TOTAL	6.5 acres	(2.6 hectares)

- Temporary (construction staging, haul road, or dredging)

Section 404 wetlands including 6.0 acres (2.4 hectares) of CAMA wetlands	8.9 acres	(3.6 hectares)
Aquatic bottom	25.6 acres	(10.2 hectares)
Uplands (excluding man-dominated areas)	0.8 acre	(0.3 hectare)
TOTAL	35.3 acres	(14.1 hectares)

The above impacts include 0.1 acre (0.04 hectare) of permanent submerged aquatic vegetation (SAV) loss and 0.7 acre (0.3 hectare) of temporary SAV loss.

A bridge in the 1993 Parallel Bridge Corridor would minimally affect birds using the project area. The 1993 Parallel Bridge Corridor would affect 0.5 acre (0.2 hectare) of potential nesting habitat and 1 acre (0.4 hectare) of foraging and resting habitat for the piping plover (federally-listed threatened species). The impact to the feeding patterns of the piping plover caused by construction activities generally would be reduced because of the abundance of unaffected feeding sites in the project area. Since 1993, piping plover breeding pairs have been observed during several years at the south end of Bodie Island (North Carolina Wildlife Resources Commission [NCWRC], unpublished data, 2003). Over the same period, piping plover breeding pairs also were recorded at the north end of Hatteras Island near Oregon Inlet (NCWRC, unpublished data, 2003). Thus, a potential exists for affecting piping plover nesting with this corridor. Dredging and beach nourishment operations associated with dredge material disposal would be subject to protective measures implemented by the National Marine Fisheries Service (NMFS) and the US Fish and Wildlife Service (USFWS) to protect sea turtles. Beaches would not be nourished in locations where the seabeach amaranth is present.

Air Quality and Noise

Since this alternative would not result in increased traffic levels over the existing situation, no air quality impact would occur. Because of its location, this corridor should have a minimal impact on noise levels other than temporary noise associated with construction activities.

2.2.5.4 Costs

In 1995, the capital cost of a bridge in the 1993 Parallel Bridge Corridor was estimated to be $88.7 million. This cost is higher than that presented in the DEIS ($54.8 million in 1993 dollars) for this corridor because:

- The overall bridge was lengthened during the 1995 bridge type study, reducing the amount of approach fills; and

- The vessel impact loads applied to the 5,000-foot (1,524-meter) multiple span navigation zone in the 1993 DEIS representative design were applied to most of the 9,987-foot (3,044-meter) main bridge. This was done to meet then-new requirements associated with scour and ship collision.

These considerations added approximately $22 million to the cost of the bridge. Additional funds for contingencies also added approximately $11 million to the total cost.

A 40-year bridge service life was assumed. Operation and maintenance costs, including the cost of rehabilitation in the middle of its service life, were estimated to be $20.1 million. Operation and maintenance costs for fixed-span, concrete bridges are relatively low for the first half of a structure's estimated service life. During this period, regular maintenance is required, including cleaning of scuppers or drains and joints and replacement of lights for navigation. Minor repairs to handrails, steel bearing plates, and concrete surfaces also might be required. In addition to maintenance, concrete bridges typically require rehabilitation after 20 to 30 years. Rehabilitation work may include repairing concrete spalls and cracks, replacement of bearings, joints, scuppers, and other miscellaneous items. The total cost of the new bridge over 40 years was estimated to be $108.8 million ($88.7 million in capital costs plus $20.1 million for operation and maintenance) in 1995 dollars.

2.2.5.5 Construction

Construction of a bridge in the 1993 Parallel Bridge Corridor would involve primarily the assembly of large precast concrete units. The footings would be cast-in-place concrete. The least expensive method for shipping all parts probably would be by barge.

The bridge superstructure in this corridor would be built using the balanced cantilever construction method from barges and a haul road. Top-down construction and construction from a work bridge would be impractical. For the main bridge, the method of construction would be from barges. When building over a water body, the easiest way to move an erection crane from place to place is by attaching it to a barge and moving the barge. For the northern approach, construction was assumed to involve temporary construction of a haul road on geotextile fabric. Here, foundations would be lighter than on the main bridge or southern approach, and crawler cranes operating on a haul road could be used to erect the precast piles. Except for the top surface, temporary haul road and permanent approach road fills were assumed to consist of fill dredged from Oregon Inlet or Pamlico Sound.

Land for construction staging would be required near the project. A staging area near the construction project would make it easier to manage the construction process, make it easier to respond to emergencies, be less costly, and reduce construction-related traffic on NC 12. The staging area would require both water and road access. A single 4.8-acre (1.9-hectare) staging site on Hatteras Island was proposed for this corridor. It was the same site used during terminal groin construction and for temporary ferry boarding and unboarding in late 1990 and early 1991.

The staging area would be used for:

- Receipt of construction materials by truck and barge;
- Loading various components onto construction barges;
- Construction management and worker trailers;
- Equipment storage; and
- Minor equipment maintenance.

Construction in this corridor was assumed to take approximately 3.5 years.

2.2.6 Ferry Alternative

A Ferry Alternative was examined during the 1991 feasibility study. The Ferry Alternative was not studied in detail in the "Environmental Consequences" chapter of the 1993 DEIS nor this FEIS for these reasons:

- It would result in a decrease in the present level of traffic service across Oregon Inlet, even though traffic predictions indicate a continuing increase in demand. This decrease in service would reduce access between Hatteras Island and the mainland for permanent residents and visitors (including visitors to the Seashore and the Refuge) and increase the evacuation time for Hatteras Island and Ocracoke Island in the event of an emergency. The decrease in access would substantially affect the economies of the islands and Dare County, which are heavily dependent upon travel and tourism industries.

- It would require extensive dredging to maintain a navigation channel 200 feet (61 meters) wide and approximately 3 miles (4.8 kilometers) long across Oregon Inlet (assuming a direct route from the Bodie Island terminal and around Bodie Island to a Hatteras Island terminal near the southern terminus of Bonner Bridge). This length would increase to as much as 18 miles (29.0 kilometers) if the Hatteras Island terminal for this alternative were placed at the emergency ferry dock that now exists in Rodanthe. Given the current problems maintaining NC 12 north of Rodanthe that have arisen since the 1991 feasibility study, the 18-mile (29.0-kilometer) route likely would be required. Thus, with 3 miles (4.8 kilometers) or 18 miles (29.0 kilometers) of dredging, this alternative would be one of the most damaging to the natural environment because of the massive amount of excavation of Oregon Inlet's bottom that would be required during the creation and maintenance of a ferry channel. Facilities on Bodie and Hatteras islands would permanently use approximately 59 acres (23.6 hectares) of wetlands, assuming a southern ferry terminal near the end of Bonner Bridge. Extensive wetlands also exist near the emergency ferry dock in Rodanthe.

- The 1991 study found that this alternative would be substantially more expensive than a bridge alternative. The Ferry Alternative's cost (construction and maintenance) would be $418.5 million (in 1991 dollars) over 40 years compared to $108.8 million (in 1995 dollars) for the construction and maintenance of a bridge in the 1993 Parallel Bridge Corridor.

Table 2-1, Table 2-2, and Table 2-3 document the transportation, coastal engineering, and environmental study findings for the Ferry Alternative. This alternative was developed based upon information and communication with the NCDOT Ferry Division in 1991. The following paragraphs describe design characteristics, operating characteristics, environmental impact potential, and costs of the Ferry Alternative.

2.2.6.1 Design Characteristics

Vessel

A Hatteras Class ferryboat was assumed for this alternative. This type of vessel has a 30-passenger car capacity. This is the same type of ferry vessel used for the Ferry Division's Hatteras Island to Ocracoke Island service. The Oregon Inlet environment is conducive to the utilization of the same type of ferry vessels.

Consideration was also given to the potential of air-cushion vehicle (Hovercraft) ferries. An air-cushion vehicle can provide for a faster travel time between terminals, and channel dredging would not be required. Large stable pads, rather than an enlarged boat basin, would be used for loading and unloading. An air-cushion vehicle, however, would not be a sound alternative to a ferry boat for the following reasons:

- Air-cushion ferries with more than a two- or three-car capacity are no longer manufactured.

- Air-cushion vehicles could be custom-manufactured for use between Bodie and Hatteras islands. However, although no cost estimates are available, a representative of British Hovercraft Corporation indicated that it was doubtful such an approach would be cost-effective even taking into account the dredging required for operation of ferry boats. (Personal communication, 1993, Curt Chatelain, British Hovercraft Corporation.)

- Even if air-cushion vehicles were readily available, the time saved by using a faster vehicle would be small in comparison to the total trip time, which includes the time it takes to load and unload either type of ferry.

- Some economies of scale (i.e., use of existing off-site maintenance facilities) would be lost because of the use of a completely different vessel.

Consideration also was given to a catamaran (Hoverspeed), designed specifically to compete with the English Channel tunnel. This vessel can carry 80 automobiles and can travel at speeds up to 50 miles per hour (80 kilometers per hour)—much faster than Hatteras Class ferry vessels. It would not be a sound alternative to a ferryboat for the same time and economies of scale reasons described above for the air-cushion vehicle.

Facilities

Although ferry service across the Oregon Inlet was provided prior to the opening of Bonner Bridge in 1963, permanent primary support facilities for the ferry service, including terminal buildings, slips, ramps, and fuel storage facilities, are no longer available with the exception of a single slip and ramp at the emergency ferry dock in Rodanthe.

The original Bodie Island terminal is now used as part of the Oregon Inlet Marina complex. Navigation channels are maintained to the landing area. Transition of this area to a permanent ferry terminal would require expansion of the existing basin and navigational channel and construction of bulkhead, slips, ramps, and a main terminal building complete with necessary support facilities. These facilities would require approximately 52 acres (20.8 hectares) of land in the area of the marina and the adjacent (former) US Coast Guard Station.

Severe erosion of the north end of Hatteras Island has destroyed the old southern terminal on Hatteras Island. New facilities would be required for the southern landing area. The 1991 study assumed the southern terminal would be in the area of the bulkhead (removed in 1994) that was used in the construction of the terminal groin project in 1989 and 1990 (see Figure 2-1). The most logical location for a terminal on Hatteras Island would be at the emergency ferry dock in Rodanthe, given the current NC 12 overwash problems north of Rodanthe. The facilities associated with this landing would require approximately 23 acres (9.2 hectares) of land.

2.2.6.2 Operating Characteristics

Capacity

Maximum safe operating capacity, rather than travel demand, tends to set the upper limit for ferry service capacity. Safe operating is defined as no less than 10-minute headways between departures and arrivals of ferry vessels within a single travel corridor. This criterion is based on the standards of the NCDOT Ferry Division.

The Ferry Alternative assumes the use of 12 Hatteras Class ferries on a schedule typical of the NCDOT Ferry Division. Such a schedule would include approximately 150 one-way trips per day across Oregon Inlet with a total capacity of 4,500 vehicles per day (vpd). Trips would be concentrated in the daytime hours with a limited number of late evening trips.

With a maximum safe operating headway of ten minutes between departures and arrivals of ferry vessels, a 30-vehicle capacity ferry, and six ferries in each direction, up to 360 vehicles per hour could be transported across the Oregon Inlet. This capacity is insufficient to meet the peak hour two-way volumes of 690, 1,030, and 1,180 vehicles estimated for the 2002 peak season weekday, weekend, and Saturday, respectively.

If the maximum hourly service (360 vehicles) could be provided 24 hours a day, the 8,640 vehicles that could be carried per day would just meet 2002 peak season weekday traffic demand (8,000 vpd). It would not meet 2002 weekend peak-hour demand (as high as 14,200 vpd). It is unreasonable, however, to assume that this maximum amount of service would be used, since it assumes full use of the ferries at all hours of the day and night and demand spread evenly over a 24-hour period.

It would be possible to create an additional ferry route between Roanoke Island and another portion of Hatteras Island that could operate safely in tandem with an Oregon Inlet ferry (but in a different channel) and provide additional capacity. This would necessitate even more ferries and more dredging, thereby raising the project cost. The idea of using a second route to increase capacity was not pursued, because even the single Oregon Inlet route proved to be a very costly alternative when compared to other crossing alternatives.

Dredging

Ferry service could not be provided without extensive dredging operations. A dredged channel 200 feet (61 meters) wide to allow the passing of two Hatteras Class ferries, a channel alignment

of approximately 3 miles (4.8 kilometers), a channel depth of approximately 14 feet (4.3 meters) below mean low water, and the removal and disposal of approximately 1.8 million cubic yards (1.4 million cubic meters) of dredging material to create the channel was assumed for the Ferry Alternative in 1991. Increasing the length of the ferry route from 3 to 18 miles (4.8 to 29.0 kilometers) would increase the amount of dredged material from 1.8 million cubic yards to 10.8 million cubic yards (1.4 million cubic meters to 8.2 million cubic meters).

2.2.6.3 Environmental Impact Potential

The environmental impact potential of the Ferry Alternative is summarized in Table 2-3. Key environmental impact concerns are as follows:

- Emergency Evacuation. A critical roadway segment in the Dare County plan for the evacuation of Hatteras and Ocracoke islands would be lost. The time required to evacuate Hatteras Island would rise. In addition, weather conditions during evacuations would threaten the safety of the ferry voyages.

- Community Services. Loss of road access to Bodie Island across Oregon Inlet would isolate the communities on Hatteras Island from the larger community of Dare County. The ground time required to transport critically ill or injured persons, and others requiring immediate medical aid, across Oregon Inlet would be increased. The ability of the fire and police service on Hatteras Island to obtain timely assistance from other departments during large-scale emergencies would be reduced. Although the school-aged population of Hatteras Island is served by school facilities on the island, extracurricular activities—including sporting events—that involve off-island travel could be curtailed or the travel time to those activities increased. Transport by ferry would double the daily operation time for removal of solid waste to a mainland landfill. An alternative system for providing telephone and electric services to Hatteras Island would have to be developed.

- Local Economy. The variety of goods and services available to island residents and visitors would become more limited than what is available at present, and the prices of available items would become more costly because of reduced accessibility. Commerce between Hatteras Island and the rest of Dare County, and even the region, would be reduced. Employment opportunities for Hatteras Island residents elsewhere in the county and region would be diminished, as would employment opportunities on Hatteras Island for nonresidents. Commercial and residential construction on the island would be curtailed.

- Regional Economy. The ease of travel for Dare County visitors to Hatteras Island and the Hatteras Island portion of the Cape Hatteras National Seashore would be reduced. Visitor levels would be affected both by the lack of capacity and by the additional time it would take to cross Oregon Inlet.

- Natural Resources. Dredging for ferry navigation would cause a loss of benthos. The area of inlet bottom disturbed would be about 200 feet (61 meters) wide and approximately 3 miles (4.8 kilometers) long or approximately 70 acres (28 hectares). This length would increase to as much as 18 miles (29.0 kilometers) if the Hatteras Island terminal were at the emergency ferry dock that now exists in Rodanthe. Given the current problems maintaining NC 12 north of Rodanthe that have arisen since the 1991 feasibility study, the 18-mile (29.0-kilometer) route likely would be required. The area disturbed in this case would be 420 acres (168 hectares).

Disposal of dredged material could affect wintering waterfowl, migrating shorebirds, and estuarine subtidal wetlands. Because of the abundance of wetlands in the project area, it can be estimated that approximately 59 acres (23.6 hectares) of wetlands would be permanently affected by ferry operating facilities on Bodie and Hatteras islands, assuming a southern ferry terminal near the end of Bonner Bridge. However, extensive areas of wetlands also exist near the emergency ferry dock in Rodanthe.

2.2.6.4 Cost

The 1991 cost estimates for the Ferry Alternative were based on the design and operating characteristics described above, as well as capital acquisition and operating and maintenance expenditures incurred by the NCDOT Ferry Division. They assumed a southern ferry terminal near the end of Bonner Bridge. Given that the 1991 ferry costs were high compared to a comparable bridge, and that the primary reason for dropping the ferry from further consideration in the 1993 DEIS was its inability to meet even existing travel demand, the costs were not revisited in this FEIS for an assumed 18-mile (29.0-kilometer) ferry route to Rodanthe.

The existing ferry service between Hatteras and Ocracoke islands was examined and cost projections were developed based on Fiscal Year 1989 expenditures for provision of service. The Hatteras to Ocracoke service was used as a basis for the financial analysis because of similarities in conditions to Oregon Inlet, such as distances and the physical constraints of limited and constantly changing navigable waterways.

The initial capital cost for Ferry Alternative equipment, facilities, and initial channel dredging would be approximately $41.5 million (1991 dollars). The annual operating and maintenance costs for the Ferry Alternative would be $8.7 million (1991 dollars). Over the 40-year life of a bridge these annual costs would total $347 million. At 20 years, the 12 ferries would have to be replaced at an additional cost of $30 million.

The total cost for the Ferry Alternative over 40 years would be $418.5 million (1991 dollars). Like the bridge alternatives, the NCDOT would incur the cost of removing Bonner Bridge when the Ferry Alternative is completed.

The capital cost estimate includes all costs associated with procurement of ferry vessels, mechanized ramp equipment, construction of retaining walls (bulkhead), and ferry terminal buildings at both the Bodie Island and Hatteras Island terminals. The cost estimate includes 12 Hatteras Class ferry vessels. Eight ramps, four per terminal, were assumed to service the fleet. Some additional storage area in the form of bulkheads also was assumed for out-of-service vessels. One main terminal building with support facilities (including offices, storage areas, maintenance area, and restrooms) would be required on Bodie Island. A secondary terminal building with only basic support facilities would be required at the Hatteras Island landing area. The initial cost of dredging a 3-mile (4.8-kilometer)-long ferry channel was assumed.

The provision of ferry service is labor-intensive and produces substantial operating and maintenance (O&M) costs. The O&M cost for the Ferry Alternative was estimated by defining expected fixed dredging, vessel and terminal labor, and maintenance costs; these costs do not vary by the number of vessels operating. Oregon Inlet service with 12 vessels would increase the Ferry Division fleet size by about 50 percent. Some economies of scale, however, would exist in the provision of the additional ferry service. Existing off-site maintenance facilities and administrative personnel could be used. These savings, however, would be offset by the added dredging cost, which would be required to keep navigation channels open. According to the

Ferry Division, the useful life expectancy of a Hatteras Class ferry vessel is 20 years. Thus, additional capital funds would need to be spent for replacement vessels every 20 years.

2.2.7 Tunnel Alternative

The Tunnel Alternative was examined during the 1991 feasibility study. The Tunnel Alternative was not studied in detail in the "Environmental Consequences" chapter of the 1993 DEIS nor this FEIS, for the following reasons:

- It would be substantially more expensive than a bridge alternative. The Tunnel Alternative's cost would be $258 million (1991 dollars) for construction and maintenance over 40 years, compared to $108.8 million (1995 dollars) for a bridge in the 1993 Parallel Bridge Corridor. The Tunnel Alternative's costs would be even higher if the bridge and scour requirements applied to the 1993 Parallel Bridge Corridor during the 1995 bridge type study were applied to the Bodie Island approach bridge that is a part of the Tunnel Alternative.

- Excavation of Oregon Inlet's bottom would be required during the construction phase. An area approximately 600 feet (182.9 meters) wide and 11,300 feet (3,444 meters) long would be affected. Approximately 150 acres (60 hectares) of inlet bottom would be disturbed. In addition, approximately 23 acres (9.2 hectares) of wetlands would be lost to tunnel approaches. Thus, the tunnel also would be one of the most damaging alternatives to the natural environment.

- The southern terminus of the Tunnel Alternative was assumed to end near the south end of Bonner Bridge. Given the cost and environmental impact of even this short tunnel, neither a longer (18-mile [29.0-kilometer]) tunnel that would end at Rodanthe nor connecting the shorter tunnel to a bridge that continues south to Rodanthe would be practical.

Table 2-1, Table 2-2, and Table 2-3 document the transportation, coastal engineering, and environmental study findings for the Tunnel Alternative.

The immersed tube Tunnel Alternative would be along a corridor approximately 800 to 1,000 feet (243.8 to 304.8 meters) east of the Bonner Bridge alignment and have a horizontal curve to intersect the approach roadways on shore. A representative alignment is illustrated in Figure 2-1. The corridor and alignment were selected to minimize the overall tunnel length. The minimum length generally is determined by the width of the water channel above the tunnel and the allowable slope of the tunnel roadway. In keeping with the scour protection design criteria of 50 feet (15.2 meters) below mean sea level used during the 1991 feasibility study, the approximate length of the main channel of the tunnel would be 5,000 feet (1,524 meters). At both ends of the main channel section, the tunnel would rise at a maximum grade of 4 percent to 5 feet (1.5 meters) above mean sea level. The overall tunnel length from portal to portal would be approximately 11,300 feet (3,444 meters). A 2,500-foot (762-meter) approach bridge would be built on Bodie Island. Approach roads on fill would be built on Hatteras Island and lead to the bridge on Bodie Island.

Sections 2.2.7.1 through 2.2.7.4 describe design characteristics, environmental impact potential, costs, and construction procedures of the Tunnel Alternative.

2.2.7.1 Design Characteristics

Design Criteria and Traffic Service

With the immersed tube tunnel, a roadway with two 13-foot (4-meter) lanes would be used (see Figure 2-2). A narrow width was assumed because of the high cost of tunnels. Unlike the bridge alternatives, the tunnel would not be wide enough to accommodate two lanes of traffic moving off Hatteras Island during an emergency. There would be no provision for pedestrians or bicyclists. Adequate ventilation could not be provided for pedestrians and bicycles.

Scour

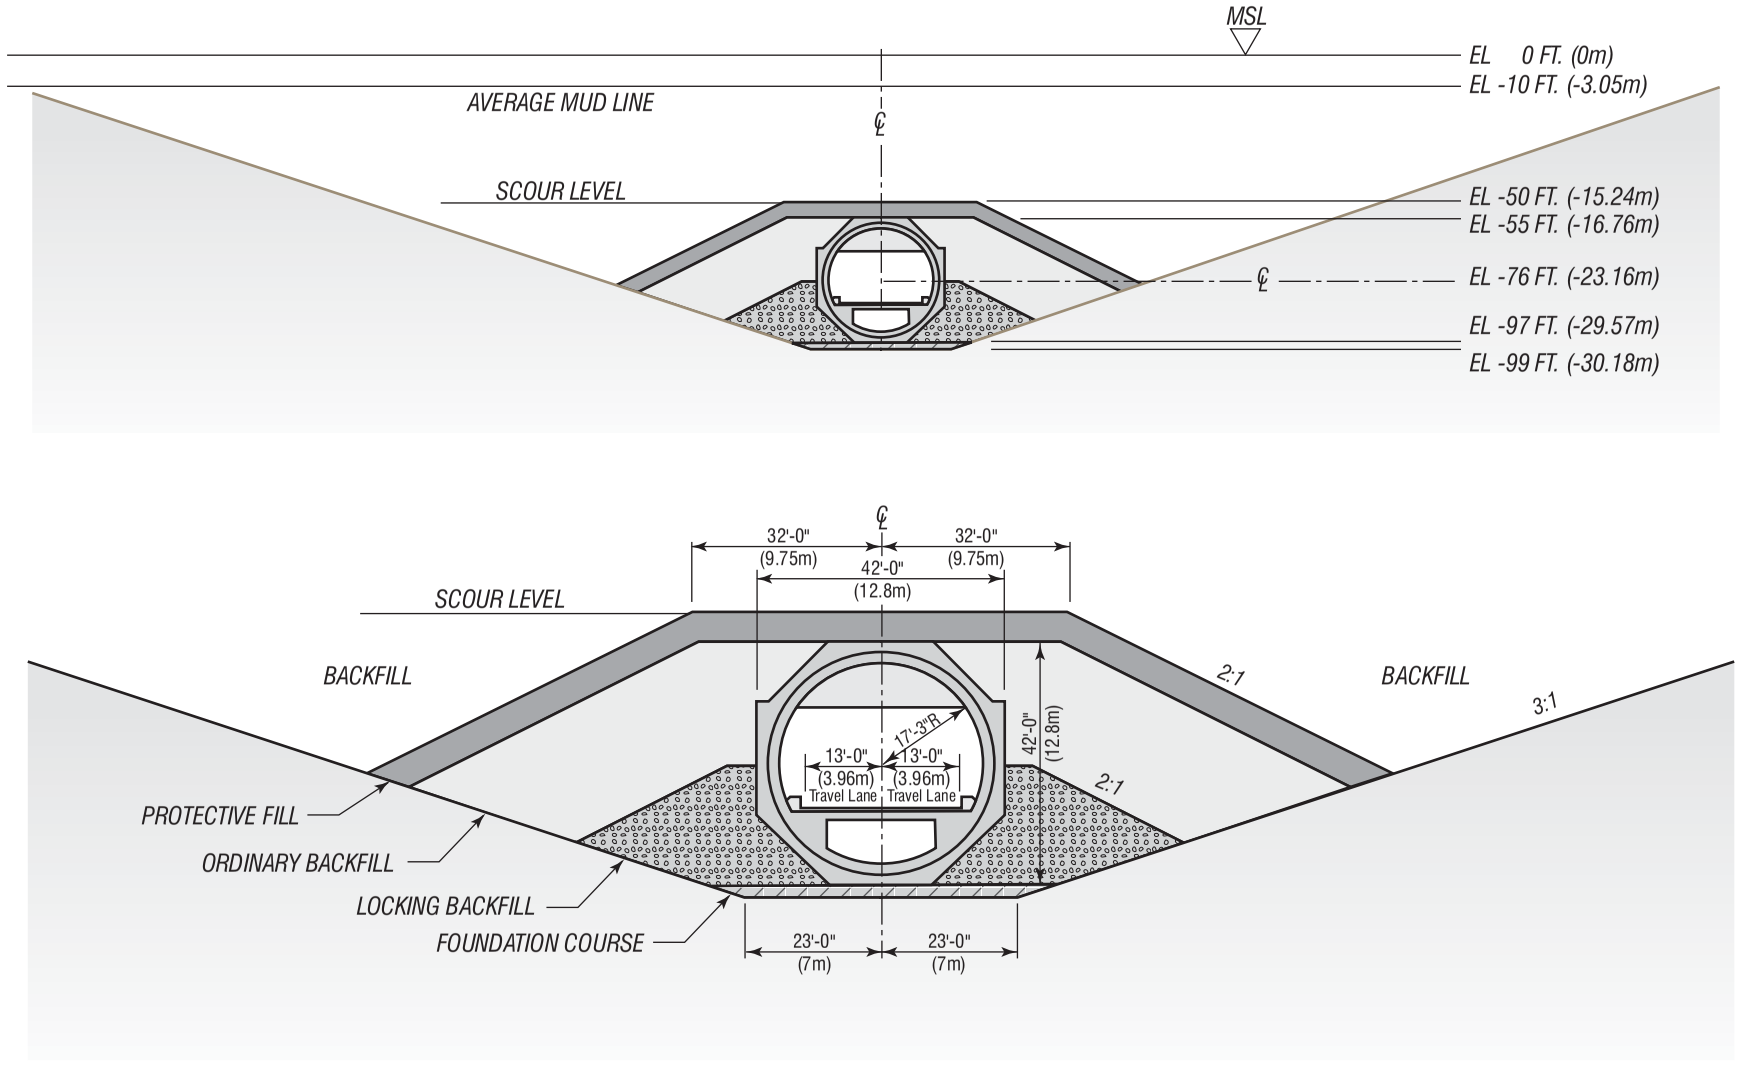
General scour at Oregon Inlet's gorge would be 50 feet (15.2 meters) below mean sea level. Thus, the scour depth criteria used for the Tunnel Alternative was 50 feet (15.2 meters) below mean sea level across the inlet. To provide a minimum of 5 feet (1.5 meters) of cover backfill over the tunnel element, the top of the tube would be at 55 feet (16.8 meters) below mean sea level.

Tunnel Components

The components of the tunnel structure would include the approach ramps, ventilation buildings, and immersed tubes in dredged trenches. The approach ramps and ventilation buildings on each side of the immersed tunnel would be constructed on shore, outside the limits of the scour areas. The top elevation of the approach would be established to protect the tunnel from the hazards of flooding in extreme weather conditions.

The tunnel would be flanked by two approach ramps descending to the portals from a low-level bridge on Bodie Island and from fill on Hatteras Island. The approach ramps would consist of a sloped embankment and a depressed roadway of two 13-foot (4-meter) lanes within a cast-in-place, reinforced concrete U-type structure. The U-type structures could be built either in an open excavation with sloping sides or within a sheeted and braced open excavation. Tunnel vertical clearance would be greater than 18 feet (5.5 meters) and would not restrict large vehicles.

To remove exhaust air and furnish fresh air through the air ducts, two ventilation buildings, one at each portal, would be required. A portal sump with pump room would be required at each building to intercept any runoff from the approach ramp leading to the portal.



The immersed portion of the tunnel between ventilation buildings would be constructed by linking prefabricated tube segments, each approximately 300 feet (91.4 meters) long. The steel shell tube segments would be constructed off-site, launched, outfitted with concrete, floated to the site, and sunk into dredged trenches onto a screeded (smoothed) foundation course.

To construct the tunnel, a large amount of material would be dredged from the channel bottom. This amount would be extremely large based on the criteria of placing the tunnel below the scour elevation of 50 feet (15.2 meters) below mean sea level.

2.2.7.2 Environmental Impact Potential

The environmental impact potential of the Tunnel Alternative is summarized in Table 2-3. Key environmental impact concerns are:

- Substantial impacts on biotic communities would occur. The portals and tunnel approaches on Hatteras Island and Bodie Island, as well as the bridge approach on Bodie Island would permanently use approximately 23 acres (9.2 hectares) of wetlands. A total of 33.3 acres

TUNNEL TYPICAL SECTION

Figure 2-2

(13.3 hectares) of wetlands would be filled. These wetlands include both estuarine intertidal emergent wetlands and estuarine subtidal wetlands. Habitat for wintering waterfowl and migrating shorebirds would be lost permanently. In addition, dredging and/or a haul road would be required on Bodie Island during construction of the approach trestle.

- Excavation of Oregon Inlet's bottom during construction would remove benthos in an area approximately 600 feet (182.9 meters) wide and 11,300 feet (3,444 meters) long (approximately 150 acres [60 hectares]).

2.2.7.3 Cost

The total cost for the Tunnel Alternative over 40 years would be approximately $258 million (1991 dollars). Including excavation, backfill, the sunken tube, portal and vents, fans, and approaches, the order of magnitude construction cost for the Tunnel Alternative would be $236 million (1991 dollars). Operation and maintenance costs could average $500,000 to $600,000 per year or between $20 million and $24 million over the 40-year life (1991 dollars). Operation and maintenance costs would include regular maintenance to ventilation fans and sump pumps, lighting, washing of tunnel walls, as well as replacement of worn equipment.

2.2.7.4 Construction

In the construction of an immersed tube tunnel, prefabricated tunnel segments would be laid in a pre-excavated trench across Oregon Inlet's bottom, linked to previously installed segments, and then covered with backfill to secure them in place (see Figure 2-2). The excavation limits for the trench would be governed by subsoil conditions, as well as the dimensions of the tube. The trench excavation would need to be deep enough to provide a minimum 2-foot (0.6-meter) thick foundation course beneath the tube, and a minimum 5-foot (1.5-meter) cover of backfill over the tube. Side slopes of the trench excavation would depend on the properties of the subsoils. In the soft channel bottom deposits, the excavation could require a 1:3 slope, or flatter. In the stiffer underlying soils, excavation slopes could be approximately 1:2. Figure 2-2 indicates a trench that is 600 feet (182.9 meters) wide. Because of the strong currents in the channel, it could be difficult to maintain the trench side slopes because of constant infilling. Spoil would be disposed in the sound or ocean.

Trench backfill would include a foundation course, locking fill, and ordinary backfill:

- The foundation course would consist of a 2- to 3-foot (0.6- to 0.9-meter) thick layer of sand and gravel.

- The locking fill would consist of graded granular material ranging in size from sand to about 3-inch size (7.6 centimeters) stone to lock the tunnel elements in place during backfill placement and provide lateral support for the tubes.

- Ordinary backfill generally is composed of clean granular material to minimize silting and turbidity during placement in the channel.

On top of the ordinary backfill, a riprap layer would be placed to provide protection from ships' anchors and, if required, from erosion because of action by the current. Because of the extreme scour problems in Oregon Inlet, special riprap design could be required to protect the tubes.

2.2.8 East Bridge Corridor

A bridge corridor east of Bonner Bridge also was examined during the 1991 feasibility study. The East Bridge Corridor was not studied in detail in the "Environmental Consequences" chapter of the 1993 DEIS, nor this FEIS for the following reasons:

- Although shorter than the 1993 Parallel Bridge Corridor, it would result in greater impacts to biotic communities and wildlife habitat on Bodie Island. This would include impacts to birds that forage, rest, and sporadically nest on the southern tip of Bodie Island.

- Cost savings resulting from a shorter structure would be offset by costs related to the risks introduced by construction in an area of greater wave activity and faster currents during storm surges and less protection from storms. Conversations with several contractors working in the Oregon Inlet area indicated that working conditions in this corridor would increase equipment, insurance, and down time costs. Thus, the cost of a bridge in this corridor would be virtually identical to the cost of a bridge in the 1993 Parallel Bridge Corridor.

Table 2-1, Table 2-2, and Table 2-3 document the transportation, coastal engineering, and environmental study findings for the East Bridge Corridor. The cost and engineering characteristics associated with the East Bridge Corridor cannot be compared to the 1993 Parallel Bridge Corridor as presented in this chapter in Section 2.12. Unlike the 1993 Parallel Bridge Corridor, the representative bridge assumed in the East Bridge Corridor was not revisited in the 1995 bridge type study because the alternative was no longer under consideration. Thus, the discussion below compares the East Bridge Corridor's cost and engineering characteristics with the 1993 Parallel Bridge Corridor as represented in the feasibility study and the DEIS. If the alignment, south abutment location, and foundations of the East Bridge Corridor's representative bridge design were altered to achieve the same objectives as the representative design in the 1993 Parallel Bridge Corridor, costs in the East Bridge Corridor would rise to an amount similar to the 1993 Parallel Bridge Corridor costs.

The representative alignment examined for the East Bridge Corridor is illustrated in Figure 2-1. It would have the following bridge length:

Southern Approach Length	1,900 feet (579 meters)
Navigation or Main Spans Length	4,500 feet (1,372 meters)
Northern Approach Length	6,500 feet (1,981 meters)
TOTAL LENGTH	12,900 feet (3,932 meters)

Fill approaches at each end of the structure would be 2,000 feet (610 meters) long on Hatteras Island and 1,000 feet (305 meters) long on Bodie Island, for a total project length of about 15,900 feet (4,846 meters). Fill would be between the natural ground and the 20-foot (6.1-meter) minimum profile grade elevation for the bridge.

The comparable representative bridge project in the 1993 Parallel Bridge Corridor (as used for comparison in the feasibility study and DEIS) would have the following bridge length:

Southern Approach Length	1,700 feet (518 meters)
Navigation or Main Spans Length	5,000 feet (1,524 meters)
Northern Approach Length	6,800 feet (2,073 meters)
TOTAL LENGTH	13,500 feet (4,115 meters)

Fill approaches at each end of the structure would be approximately 2,000 feet (610 meters) long on Hatteras Island and 1,300 feet (396 meters) long on Bodie Island, resulting in a total project length in the East Bridge Corridor of approximately 16,800 feet (5,120 meters).

The following paragraphs describe design characteristics, environmental impact potential, costs, and construction procedures of the East Bridge Corridor in contrast to the 1993 Parallel Bridge Corridor.

2.2.8.1 Design Characteristics

Design Criteria

The design criteria used for a representative bridge in the East Bridge Corridor were the same as those presented for the 1993 Parallel Bridge Corridor, as defined in the 1993 DEIS and after the 1995 bridge type study. The only exceptions were the scour criteria. Scour depths used for the East Bridge Corridor representative project were not as deep as those defined for the 1993 Parallel Bridge Corridor during the 1995 bridge type study. Scour depths assumed for the East Bridge Corridor ranged from 20 feet (6.1 meters) below mean sea level to 75 feet (22.9 meters) below mean sea level. The comparable 1993 Parallel Bridge Corridor in the 1993 DEIS used the same design criteria as the East Bridge Corridor representative project except a 70-foot (21.3-meter) preliminary depth of scour was used in the location where a depth of 75 feet (22.9 meters) was specified for the East Bridge Corridor.

Bridge Type Options

During the feasibility study and preparation of the 1993 DEIS, several superstructure (structural components spanning the distance between piers) options were evaluated for both the East and 1993 Parallel Bridge Corridors. Two basic types were considered: precast girders and segmental box girders.

For the navigation zone, precast girders with a span length of 225 to 240 feet (68.6 to 73.1 meters) and box girders with a span length of 220 to 400 feet (67.1 to 121.9 meters), were evaluated. Outside the navigation zones, precast girders with spans 90 feet (27.4 meters) long and 135 to 145 feet (41.1 to 44.2 meters) long were considered, as well as box girders with spans of 140 to 150 feet (42.7 to 45.7 meters).

For foundations, 54-inch (135-centimeter) precast concrete cylinder piles were assumed. Based upon the geotechnical information available at the time for the existing structure site and a 70-foot (21.3-meter) scour depth, pile tip elevations between 100 and 150 feet (30.5 and 45.7 meters) below mean sea level, depending upon structure type and load, were assumed. At locations requiring a 50-foot (15.2-meter) scour depth, pile tip elevations were assumed to range between 75 and 95 feet (22.9 and 29.0 meters) below mean sea level.

Other

At each end of the East and 1993 Parallel Bridge corridors, fill at a 3:1 slope was assumed instead of structure between the natural ground and the 20-foot (6.1-meter) minimum profile grade elevation for the bridge. Characteristics of recreational access opportunities and utility relocation were the same as for the 1993 Parallel Bridge Corridor.

2.2.8.2 Environmental Impact Potential

The environmental impact potential of the East and 1993 Parallel Bridge corridors is summarized in Table 2-3. Most environmental impacts of the East Bridge Corridor are expected to be similar to those of the 1993 Parallel Bridge Corridor. The natural resource impact of this alternative in contrast to the 1993 Parallel Bridge Corridor is the key environmental concern. The East Bridge Corridor is shorter than the 1993 Parallel Bridge Corridor. Rather than minimizing harm, however, construction of a bridge in the East Bridge Corridor would cross the Bodie Island spit far from its end in a good shorebird nesting habitat. Suitable habitat for federally protected birds also is more likely to occur in the East Bridge Corridor than in the 1993 Parallel Bridge Corridor. The East Bridge Corridor would dissect larger and more diverse habitats than the 1993 Parallel Bridge Corridor, potentially causing a greater adverse impact to wildlife. The permanent and temporary use of wetlands also would be greater than with the 1993 Parallel Bridge Corridor.

2.2.8.3 Costs

The total cost for a bridge in the East Bridge Corridor would be virtually identical to a comparable bridge in the 1993 Parallel Bridge Corridor. Construction costs (in 1991 dollars) in the East Bridge Corridor would be as much as $55.5 million compared to $54.8 million for a comparable bridge in the 1993 Parallel Bridge Corridor. (The East Bridge cost of $55.5 million cannot be compared directly to the 1993 parallel corridor bridge capital cost of $88.7 million presented in Section 2.15 because it has not undergone the same post-public hearing and bridge type study refinements. If the alignment, south abutment location, and foundations of the East Bridge Corridor's representative project were altered to achieve the same objectives as the post-type study 1993 Parallel Bridge Corridor project, its costs would rise to a level similar to $88.7 million.)

Although the East Bridge Corridor is shorter than the 1993 Parallel Bridge Corridor and presumably cheaper because there would be less bridge to build, the additional construction risk of working closer to Oregon Inlet would add $4.6 million (1991 dollars) to the East Bridge cost. This addition would make the total cost virtually identical to the cost of a bridge in the 1993 Parallel Bridge Corridor. This additional cost was identified through discussions with contractors who have experience constructing bridges in an environment like that of Oregon Inlet. The cost reflects the use of sea-going barges, higher insurance costs, and increased down time during inclement weather (see Section 2.2.8.4).

Operation and maintenance costs for a bridge in the East Bridge Corridor would be the same as those for the 1993 Parallel Bridge Corridor.

2.2.8.4 Construction

Construction in the East Bridge Corridor would involve greater risks than construction in the 1993 Parallel Bridge Corridor. The East Bridge Corridor is an area of greater wave activity. Faster currents during storm surges and less protection from storms would necessitate the use of more stable jack-up barges, additional insurance, and increased down time because of inclement weather.

During calm periods, the difference in currents and waves between the East Bridge Corridor and the 1993 Parallel Bridge Corridor is small. The difference increases markedly, however, as weather conditions grow severe. Oregon Inlet is narrower at the East Bridge Corridor. Currents at the East Bridge Corridor have been estimated to increase to almost double those at the 1993 Parallel Bridge Corridor under extreme ocean storm surges. There is less wave activity parallel to Bonner Bridge since it is sheltered from ocean waves by Bodie and Hatteras islands to a greater extent than the East Bridge Corridor. Also, the shoals between the two corridors cause many waves to break before they can reach a corridor immediately adjacent and parallel to Bonner Bridge; this would affect construction barges in the East Bridge Corridor.

2.2.9 West Bridge Corridor

A bridge corridor to the west of Bonner Bridge and farther into Pamlico Sound than the 1993 Parallel Bridge Corridor also was considered during the 1991 feasibility study (see Figure 2-1). It was examined solely because it would have the advantage of placing a replacement bridge in an area where the navigational channel is defined more clearly. This corridor is similar to Corridor Alternative 1 that was examined and then dropped from consideration in the 2002 corridor alternatives studies described in Section 2.3.

In 1991, it was concluded that this corridor would result in a crossing substantially longer than the other crossing alternatives considered at that time (approximately 6 miles [9.6 kilometers] long compared to 2.7 miles [4.3 kilometers] for the 1993 Parallel Bridge Corridor), would involve greater cost, and would result in more difficult and less desirable connections to NC 12 on either end of the bridge.

In 1991, it was concluded that use of the West Bridge Corridor would not minimize harm to the Refuge, although at the time the long-term maintenance of NC 12 from Oregon Inlet to Rodanthe was not component of the alternatives studies. The West Bridge Corridor would pass through additional environmentally sensitive areas on the Refuge in contrast to the 1993 Parallel Bridge Corridor. It would pass through the waters of Pamlico Sound just off Hatteras Island, which are used by thousands of wintering waterfowl for feeding and resting. It also would be a location close to numerous dredge material islands used extensively by colonial waterbirds for nesting. The West Bridge Corridor's use of wetlands would be as follows:

Community	*Permanent Fill acres (hectares)*	*Temporary Construction Impact acres (hectares)*
Low Shrub/Grassland	6.5 (2.6)	3.7 (1.5)
Maritime Shrub Thicket	0.3 (0.1)	1.5 (0.6)
Saltmeadow Flats	0.0 (0.0)	1.3 (0.5)
Needlerush Pockets	0.0 (0.0)	1.0 (0.4)
Smooth Cordgrass Stands	1.0 (0.4)	1.3 (0.5)
Mudflats	0.0 (0.0)	1.0 (0.4)
Submerged Aquatic Vegetation (SAV) Beds	0.0 (0.0)	0.5 (0.2)
TOTAL	**7.8 (3.1)**	**10.3 (4.1)**

The permanent and temporary use of wetlands would be greater than those associated with the 1993 Parallel Bridge Corridor (see Table 2-3).

Finally, the West Bridge Corridor would provide for the relocation of a portion of NC 12 that is threatened by beach erosion. This, however, was not considered a positive attribute during the 1991 to 1994 studies for reasons discussed in Section 2.2.1.4. For these reasons, a corridor to the west of Bonner Bridge was eliminated from consideration early in the feasibility study process.

2.3 2002 Pamlico Sound Bridge Corridor Alternatives Study

Since the 1994 public hearings and the selection of the 1993 Parallel Bridge Corridor as the Preferred Alternative, changes in the setting of the project resulted in the decision to assess additional alternatives. NC 12 is regularly threatened by shoreline erosion and overwash. Three areas on NC 12, or "hot spots," between Oregon Inlet and Rodanthe are especially vulnerable. One hot spot, known as the Canal Zone Hot Spot (shown on Figure 1-1), is immediately south of the southern terminus of Bonner Bridge and is already overwashed during minor storm events.

The issue of shoreline erosion and overwash was recognized in the previous studies as noted in the assumptions presented in Section 2.2.1.4. It was assumed, however, in the 1993 DEIS that in the short term NC 12 could be moved farther west as needed. Since the 1993 DEIS, the Outer Banks Task Force (OBTF) was established to develop a long-term protection and maintenance plan for the transportation system on Hatteras and Ocracoke islands. This partnership includes representatives from the NCDOT, the Federal Highway Administration (FHWA), the USACE, the NPS, the USFWS, the NMFS, the North Carolina Department of Environment and Natural Resources (NCDENR), and other state and federal environmental resource and regulatory agencies. The Memorandum of Agreement (MOA) establishing the OBTF has expired, but the OBTF continues to meet to share information and to foster continued relationships.

The OBTF's goals under its MOA included:

- Preserving the natural barrier island system;
- Minimizing impacts to Hatteras and Ocracoke islands; and
- Maintaining access to and on the islands so that the transportation system is safe, efficient, and has minimal impact on the environment.

A part of the work of the OBTF under its MOA was to develop both short-term and long-term plans for maintaining NC 12 in light of recent trends of shoreline erosion and highway overwash. Bonner Bridge replacement decisions now consider the placement of a replacement bridge within the context of these larger OBTF goals. Thus, this section and Sections 2.4 to 2.7 examine several new bridge corridor alternatives with respect to natural resource impacts, costs, natural resource agency input, and other evaluation criteria. This material from the studies described in this section was presented in the report, *Evaluation of Corridor Alternatives* (Parsons Brinckerhoff Quade & Douglas, Inc., January 2003).

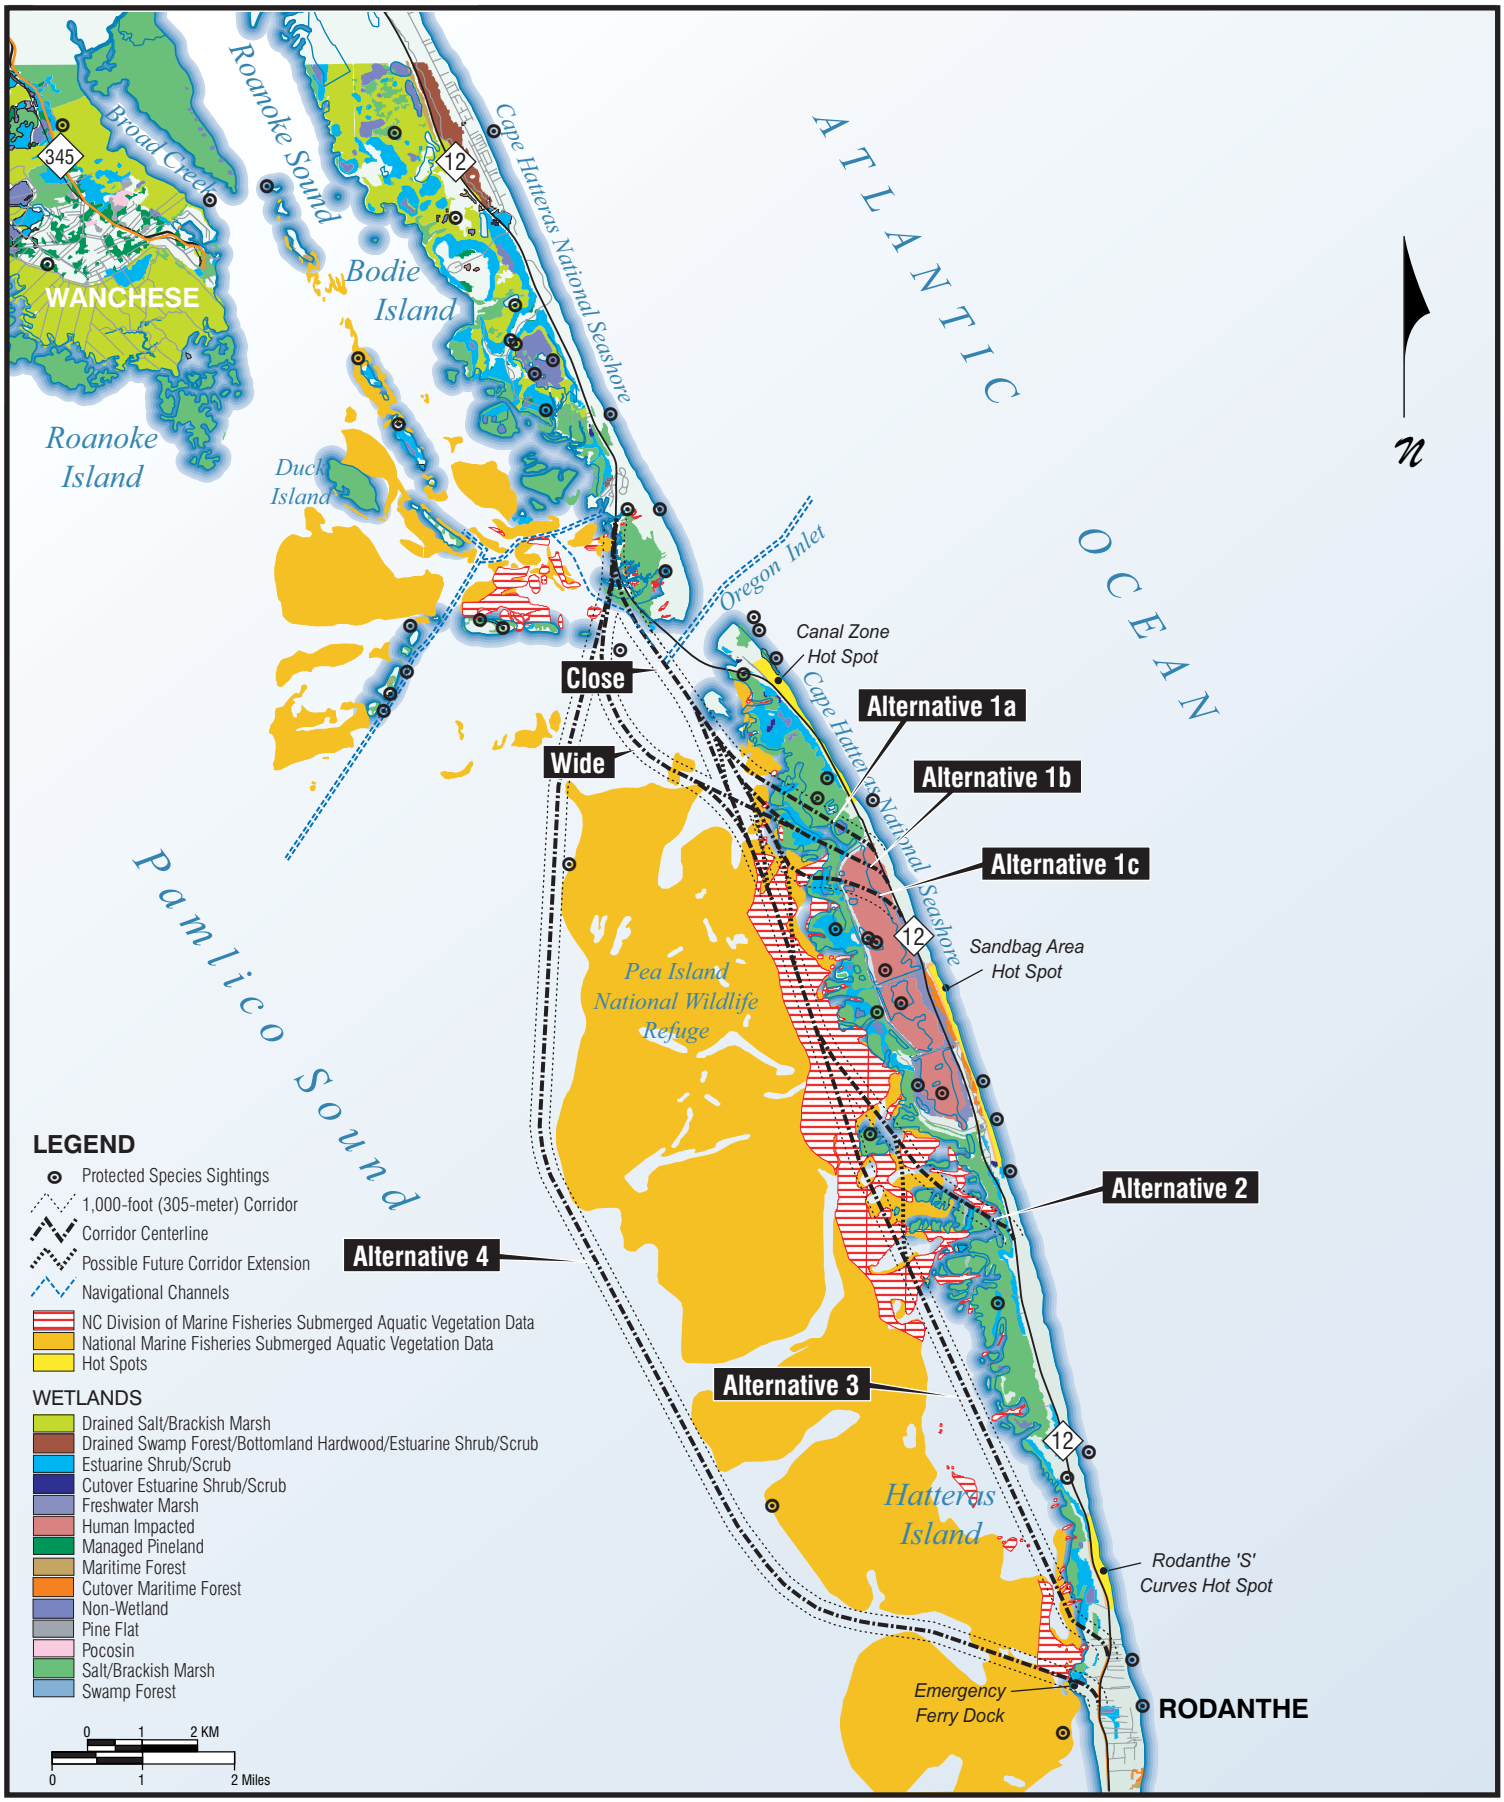
The National Environmental Policy Act (NEPA)/Section 404 Merger Team meetings are a formal means for early involvement in the project development process for state and federal

environmental resource and regulatory agencies that have an interest in the issuance of USACE dredge and fill permits for wetland and stream impacts under the terms of Section 404 of the Clean Water Act. The findings of the alternatives studies described in this section and in Section 2.4 were discussed with the NEPA/Section 404 Merger Team. More information regarding the NEPA/Section 404 Merger Team is in Section 8.3.1. The first meeting of the Merger Team for this project was held on July 31, 2002.

2.3.1 Screening Criteria

During the 2002 studies, potential new corridors were developed and screened for suitability based on several criteria, including:

- The corridor and the southern NC 12 termini locations should be potentially compatible with the April 1938 Executive Order 7864 creating the Pea Island National Wildlife Refuge, the National Wildlife Refuge System Improvement Act of 1997, and Refuge's Management Plan;
- The corridor and NC 12 termini locations should be potentially eligible to receive a non-impairment determination from the NPS;
- Selected corridors should minimize impacts to multiple resources, including SAV, wetlands, and federally protected species; and
- Corridor locations should be compatible with a possible connection to a longer bridge extending further south (potential long-term solution for maintenance of NC 12) or other long-term solutions to NC 12 maintenance.



2.3.2 Corridor Alternatives

Corridors were identified to meet the screening criteria and to avoid sensitive resources to the extent possible. The corridors were placed to provide a bridge that is constructible, crosses navigation channels at a reasonable angle, and avoids the rising sand island west of the south shoulder of Oregon Inlet. The three areas where the corridor rejoins NC 12 on Hatteras Island are:

- Between the Canal Zone and Sandbag Area hot spots (Corridor Alternative 1);
- Between the Sandbag Area and Rodanthe 'S' Curves hot spots (Corridor Alternative 2); and
- South of the Rodanthe 'S' Curves Hot Spot (Corridor Alternatives 3 and 4).

All of the corridor alternatives begin on Bodie Island at the existing northern endpoint of Bonner Bridge near the (former) US Coast Guard Station and the Oregon Inlet Marina. The corridor alternatives are shown in Figure 2-3.

Corridor Alternatives 1 through 3 each have a *close* and a *wide* option. The *wide* option is placed farther to the west, increasing the distance between the most dynamic portion of Oregon Inlet and the bridge. The centerlines shown in each corridor on Figure 2-3 are representative of a broad range of potential alignments. The corridors are:

2002 CORRIDOR ALTERNATIVES AND RESOURCES

Figure 2-3

1. Corridor Alternative 1

   Three representative terminus options, or sub-alternatives, were examined for Corridor Alternative 1. Each of the sub-alternatives makes landfall in the Refuge south of the Canal Zone Hot Spot: Corridor Alternative 1a makes landfall on Hatteras Island, just north of the Refuge's wildlife management ponds; Corridor Alternative 1b crosses the Refuge just inside the Refuge's north pond; and Corridor Alternative 1c divides the north pond to a greater extent.

   The *wide* option adds approximately one-half mile (0.8 kilometers) to the length of the bridge. The *close* Corridor Alternative 1 is approximately 5.7 miles (9.1 kilometers) long, and the *wide* Corridor Alternative 1 is approximately 6.2 miles (9.9 kilometers) long.

2. Corridor Alternative 2

   Corridor Alternative 2 ends just south of the second, or Sandbag Area, hot spot. The *close* option is approximately 9.7 miles (15.6 kilometers) long, and the *wide* option is approximately 9.9 miles (15.8 kilometers) long.

3. Corridor Alternative 3

   Corridor Alternative 3 ends just south of the Rodanthe 'S' Curves Hot Spot. The *close* option is approximately 14.6 miles (23.5 kilometers) long, and the *wide* option is approximately 14.8 miles (23.8 kilometers) long.

4. Corridor Alternative 4

   Corridor Alternative 4 also ends just south of the Rodanthe 'S' Curves Hot Spot, but is further west in the Pamlico Sound than the first three corridor alternatives. It has a southern terminus that is near the emergency ferry dock in Rodanthe. It is approximately 17.1 miles (27.4 kilometers) long.

Options for extending the bridge further south (i.e., potential long-term solution) are also shown for each corridor centerline drawn in Figure 2-3. It was assumed that NC 12 would be maintained on Hatteras Island at Rodanthe and the adjoining communities of Waves and Salvo.

2.3.3 Evaluation Factors

To aid in the identification and evaluation of corridors, the following sensitive environmental features were mapped using a Geographic Information System (GIS); the features are shown in Figure 2-3:

- Hot spots;
- Known sites for federally protected species;
- Marsh and sand islands;
- USACE navigation channels;
- NCDENR's Division of Coastal Management (DCM) wetland mapping;

- SAV locations mapped by the NMFS; and

- SAV locations mapped by the NCDENR's Division of Marine Fisheries (DMF).

Other data evaluated but not shown in Figure 2-3 include Refuge land cover classifications, water depth, NPS vegetation types, and Refuge management areas, trails, and other facilities. Public perception and affordability also were evaluation factors.

2.3.3.1 Wetlands

Much of Bonner Bridge currently crosses salt marsh communities. The predominant wetland types crossed by the corridor options include salt/brackish marsh, estuarine shrub-scrub, maritime forest, and pond. Locating a replacement bridge to the west generally would be moving into areas occupied by less wetland and more open water-mudflat habitat. Wetland data in Figure 2-3 is from the DCM.

2.3.3.2 Protected Species

There are several federally-listed threatened and endangered species in Dare County. They are listed in Section 3.7.7 in Table 3-24.

The North Carolina Natural Heritage Program has provided data to the North Carolina Center for Geographic Information and Analysis (CGIA) that show occurrences of Natural Heritage elements in the project area (see Figure 2-3). Natural Heritage elements include state and federally-listed threatened and endangered species as well as other important species. The CGIA does not release information regarding what species is associated with Natural Heritage elements other than threatened and endangered species. The Refuge is considered a Significant Natural Heritage Area.

2.3.3.3 Submerged Aquatic Vegetation

The dynamic nature of the area around Oregon Inlet results in ephemeral habitats, particularly in shallow water and shoreline areas. The NMFS and the Division of Marine Fisheries SAV data used in the 2002 corridor study are shown in Figure 2-3. The NMFS data is based on aerial photography from the early 1990s. The DMF data were generated from boat surveys conducted in the late 1990s. Information on the importance of SAV is presented in Section 3.7.3.1.

2.3.3.4 Biotic Communities

Plant communities consist of primarily wetland communities and some upland maritime shrub-scrub and dune communities. Additional information on biotic communities is in Section 3.7.3.

2.3.3.5 Water, Shellfish, and Fisheries Resources

The estuarine waters of the Pamlico Sound are classified by the NCDENR Division of Water Quality (DWQ) as market shellfish – salt waters (SA) and high-quality waters (HQW) (Pasquotank Basin, Stream Index 30-22). Shallow waters and extensive mudflats within the project area are considered valuable for fisheries resources and important foraging habitat for birds. Additional information on water resources can be found in Section 3.7.2. Additional information on fish and shellfish resources can also be found in Section 3.7.6.2.

2.3.3.6 Public Perception

The area around the Refuge's wildlife management ponds is considered to be of global importance for shorebirds and migratory waterfowl. It is also an area that receives considerable recreational use by bird watchers. The Refuge staff anticipates that impacts to the ponds, other than perhaps those that would occur in association with natural shoreline erosion, would generate public concern, as would impacts to the walking areas around the northernmost freshwater pond.

2.3.3.7 Project Affordability

Because the current bridge is reaching the end of its service life, (at the time of this analysis - 2002) construction of a replacement bridge was scheduled to begin by 2008 so that it would be open by 2012. For this FEIS, these dates are now 2009 and 2013, respectively.

The affordability of the alternatives was based on the NCDOT's 2006 to 2012 TIP that included total funding of $184,000,000 for Bonner Bridge (TIP Project No. B-2500). Of that total, $180,000,000 was for construction and $4,000,000 was for right-of-way acquisition. The Bonner Bridge replacement project at the time of the alternatives analysis represented 34 percent of available statewide bridge replacement funds programmed for 6 years.

The estimated cost for each corridor alternative is in Table 2-4. All cost estimates are for a 4-year construction period and are in year 2000 dollars. The *close* options are more expensive than the *wide* options for each corridor alternative because the required navigation zone (spans with navigation height and width) would be longer with the *close* options. The natural channel or gorge is less stable in Oregon Inlet than in Pamlico Sound.

2.3.4 Alternatives Analysis

A comparison of the corridor alternatives illustrated in Figure 2-3 is shown in Table 2-4.

2.3.4.1 Corridor Alternative 1

Corridor Alternative 1 would have the greatest impact potential to wetlands of the four corridors, although extending the bridge structure to a point near NC 12 would minimize those impacts. The type of wetland impacts would vary depending on the project location; for example, 1a would affect primarily salt/brackish marsh, 1b would affect primarily estuarine shrub-scrub, and 1c would affect primarily the wildlife management ponds. There would be no difference in wetland impacts between the *close* and *wide* options for any of the corridor alternatives. Corridor Alternative 1a would cross 1.2 miles (1.9 kilometers) of Refuge land, 1b would cross 1.3 miles (2.1 kilometers), and 1c would cross 0.9 miles (1.4 kilometers) of Refuge land.

Based on conversations with Refuge representatives, Corridor Alternative 1 was expected to generate a substantial amount of public comment because of its proximity to waterfowl feeding and nesting areas. Splitting the pond under Corridor Alternative 1c would disrupt the ability to walk around the pond and would create a divide that would be much wider than what would be needed if the pond were divided for a resource management purpose. If the pond were split, a second set of pumps would be needed to regulate the water levels.

This alternative would have the greatest amount of bridge structure on the Refuge land, but would affect the least amount of SAV. The *wide* and *close* options would have a similar impact on SAV for all of the alternatives.

Table 2-4. 2002 Corridor Alternatives Impact Comparison

Impact	Corridor Alternatives			
	1 – Canal Zone Endpoint	2 – Sandbag Area Endpoint	3 – Rodanthe Area Endpoint 1	4 – Rodanthe Area Endpoint 2
Relation to Hot Spots	Ties in south of the Canal Zone Hot Spot	Ties in south of the Sandbag Area Hot Spot	Ties in south of the Rodanthe 'S' Curves Hot Spot	Ties in near the emergency ferry dock at Rodanthe (south of the Rodanthe 'S' Curves Hot Spot)
Estimated Impact to SAV in Miles (km) Crossed	a-0.86 (1.38), b-0.84 (1.34), c-1.33 (2.13) *wide* alternative adds 0.22 (0.35) to each sub-alternative	5.07 (8.11) (*close*) 5.29 (8.46) (*wide*)	6.46 (10.34) (*close*) 6.68 (10.69) (*wide*)	1.48 (2.37)
Estimated Impact to Wetlands[1] in Miles (km) Crossed	a-1.2 (1.9), b-1.1 (1.8), c-1.1 (1.8)	0.18 (0.29)	0.33 (0.53)	0.30 (0.48)
• Salt/Brackish Marsh in Miles (km)	a-1.1 (1.8), b-0.24 (0.38), c-0.29 (0.46)	0.17 (0.27)	0.22 (0.35)	0.13 (0.21)
• Estuarine Shrub-Scrub in Miles (km)	a-0.1 (0.16), b-0.53 (0.85), c-0.02 (0.03)	0.01 (0.02)	0.11 (0.18)	0.17 (0.27)
• Maritime Forest in Miles (km)	a-0.0, b-0.0, c-0.20 (0.32)	0.00	0.00	0.00
• Human-Impacted (wildlife management ponds) in Miles (km)	a-0.0, b-0.33 (0.53), c-0.60 (0.96)	0.00	0.00	0.00
Threatened or Endangered Species	Might impact protected species and habitats	Might impact protected species and habitats	Might impact protected species and habitats	Might impact protected species and habitats
Affect on Bird-Watching at Refuge	Corridor in close proximity to wildlife management ponds	Avoids impacts to bird watching since public access points are only at the northern-most pond	Avoids impacts to bird watching	Avoids impacts to bird watching
Estimated Total Length of Bridge in Miles (km)	5.7 (9.1) (*close*) 6.2 (9.9) (*wide*)	9.7 (15.6) (*close*) 9.9 (15.8) (*wide*)	14.6 (23.5) (*close*) 14.8 (23.8) (*wide*)	17.1 (27.4)
Estimated Total Length of Bridge on Refuge Land in Miles (km)[2]	a-1.2 (1.9), b-1.3 (2.1), c-0.9 (1.4)	0.17 (0.27)	0.00	0.00
Estimated Cost of Bridge (Four-Year Construction) in year 2000 dollars	$142,000,000 (*close*) $138,000,000 (*wide*)	$240,000,000 (*close*) $230,000,000 (*wide*)	$357,000,000 (*close*) $347,000,000 (*wide*)	$260,000,000
Cost per Year	$35,500,000 (*close*) $34,500,000 (*wide*)	$60,000,000 (*close*) $57,500,000 (*wide*)	$89,250,000 (*close*) $86,750,000 (*wide*)	$65,000,000
Percent of Annual Available Bridge Replacement Funds ($90,000,000)	39.4 (*close*) 38.3 (*wide*)	66.7 (*close*) 63.8 (*wide*)	99.2 (*close*) 96.4 (*wide*)	72.2
Possible Construction Techniques	Combination of barge access and work bridge	Combination of barge access and work bridge	Combination of barge access and work bridge	Mostly floating access

[1] The sum of the different wetland types might not equal the total because of rounding.
[2] The bridge section through the Refuge would be temporary. This section would be removed upon construction of the long-term solution.

Corridor Alternative 1 would be the least expensive alternative and would be less expensive than the TIP funds for the Bonner Bridge replacement project in 2002. However, the expense and impact of the on-going maintenance of NC 12, including beach nourishment, dune maintenance, and repairs required because of highway overwash during storms, would continue south of the terminus of Corridor Alternative 1 until a long-term solution to NC 12 maintenance, at an additional cost, could be implemented for NC 12 to Rodanthe.

A Refuge representative indicated that the Canal Zone Hot Spot may have extended south to a point across from the northern edge of the first pond. Therefore, the available "window" between the Canal Zone Hot Spot and the North Pond might be smaller than what is depicted in Figure 2-3. Alternatives studies in 2005 and discussed in Section 2.6, found that over time, the Canal Zone Hot Spot and the Sandbag Area Hot Spot will expand and meet.

2.3.4.2 Corridor Alternative 2

Corridor Alternative 2 would extend south of the second hot spot. It would cross approximately 0.17 mile (0.27 kilometer) of Refuge land.

Corridor Alternative 2 would have the least linear impact on Refuge wetlands; however, it would enter into an area of SAV. A work bridge is assumed (and included in the cost estimates) to reduce the severity of the impact. Corridor Alternative 2 would have the greatest impact on SAV when one combines the impact of the initial bridge (5.1 to 5.3 miles [8.2 to 8.5 kilometers]) with the impact of building a possible future bridge extension (1.5 miles [2.4 kilometers]) plus the impact of removing the no-longer-needed portion of the initial bridge (1.4 miles [2.3 kilometers]). The impact would be 8.0 to 8.2 miles [12.9 to 13.2 kilometers].

Corridor Alternative 2 *wide* would be approximately 25 percent more expensive than the TIP funds allocated for Bonner Bridge in 2002. Corridor Alternative 2 *close* would be 30.4 percent more expensive than the 2002 allocated TIP funds. In addition, the expense and impact of the on-going maintenance of NC 12, including beach nourishment, dune maintenance, and repairs required because of highway overwash during storms would continue south of the terminus of Corridor Alternative 2 until a long-term solution to NC 12 maintenance could be implemented for NC 12 to Rodanthe.

2.3.4.3 Corridor Alternative 3

Corridor Alternative 3 would be the most expensive of the four alternatives. Corridor Alternative 3 *wide* is 88.6 percent more expensive than the TIP funds allocated in 2002, and Corridor Alternative 3 *close* is 94.0 percent more expensive.

Corridor Alternative 3 would affect 6.5 to 6.7 miles (10.4 to 10.7 kilometers) of SAV. It would completely avoid use of Refuge land, which is a protected resource under Section 4(f) of the US Department of Transportation Act of 1966. (See the introduction to Chapter 5 for a description of the requirements of Section 4(f)).

2.3.4.4 Corridor Alternative 4

Corridor Alternative 4 would include some construction cost savings. There would be barge access for most of the bridge construction, since it would be in deeper water and away from SAV areas. The use of a work bridge, which the other three alternatives would require, is more expensive. Using the year 2000 dollars presented in Table 2-4 that were used in this comparison of alternatives, a bridge in this corridor would be approximately 41.3 percent more expensive

than the then (2002) currently allocated Bonner Bridge replacement TIP funds. Its costs are comparable to those associated with Corridor Alternative 2.

Corridor Alternative 4 is the second most preferable alternative from a wetlands and SAV impacts perspective. It also would not cross Refuge land.

2.3.5 Corridor Selected for Detailed Evaluation

At its February 12, 2003, meeting, the NEPA/Section 404 Merger Team (Section 8.3.1.2) selected Corridor Alternative 1 *wide* and Corridor Alternative 4 to be studied in detail in the FEIS. Corridor Alternatives 2 and 3 were removed from consideration because of higher cost and natural resource impacts.

Subsequent to the February NEPA/Section 404 Merger Team Meeting, the USFWS concluded that it would be unlikely that a bridge in Corridor Alternative 1 could be found compatible with the April 1938 Executive Order 7864, which reserved the Refuge to advance the purposes of the Migratory Bird Conservation Act, or with the National Wildlife Refuge System Improvement Act of 1997. Without such a compatibility determination, the USFWS could not issue a permit for the construction of a bridge on new alignment within the Refuge. As a result, on September 10, 2003, the NEPA/Section 404 Merger Team revised their previous decision to study in more detail Corridor Alternatives 1 *wide* and 4 to have additional studies conducted only for Corridor Alternative 4. Recognizing that the cost of a bridge in this corridor would be greater than the funds allocated to the project in the current TIP and that the cost of all alternatives has continued to rise since this analysis of alternatives, the NCDOT was committed to exploring and identifying other additional sources of funds to build this alternative should it be selected as the Preferred Alternative.

Prior to the decision to narrow the scope of the assessment to Corridor Alternative 4, the NCDOT met with Dare County officials and held three Citizen Informational Workshops (two on June 26, 2003, one on July 22, 2003). At the meeting and the workshops, concerns were raised about the continued provision of access to and within Refuge if a replacement bridge were built in Corridor Alternative 4 bypassing the Refuge. Refuge representatives indicated that some type of access within the Refuge would be maintained if a replacement bridge were placed within Corridor Alternative 4. A joint study between the NCDOT, the USFWS, and the NPS would address how best to provide future access within the Refuge.

Henceforth in the FEIS, Corridor Alternative 4 is referred to as the Pamlico Sound Bridge Corridor.

2.4 2003 Pamlico Sound Bridge Corridor Alignment Alternatives Study

On September 10, 2003, following a July 23, 2003 meeting, the NEPA/Section 404 Merger Team selected the Pamlico Sound Bridge Corridor (Corridor Alternative 4) to be studied in detail in the FEIS. Additional data were gathered and evaluated in order to develop alignment alternatives within the Pamlico Sound Bridge Corridor. Section 2.4.3 identifies the resources that were studied in more detail. Results of the study are presented in *Evaluation of Alignment Alternatives* (Parsons Brinckerhoff Quade & Douglas, Inc., July 2003). Using this information, alignments were drawn to meet the screening criteria described in Section 2.4.1 to the extent possible.

Centerlines were placed to insure constructability, to cross navigation channels at a reasonable angle, to avoid the rising sand island west of the south shoulder of Oregon Inlet, and to end between the Rodanthe 'S' Curves Hot Spot (and the southern Refuge boundary) and the emergency ferry dock in Rodanthe.

2.4.1 Screening Criteria

Potential alignments were screened for suitability based on several criteria, including:

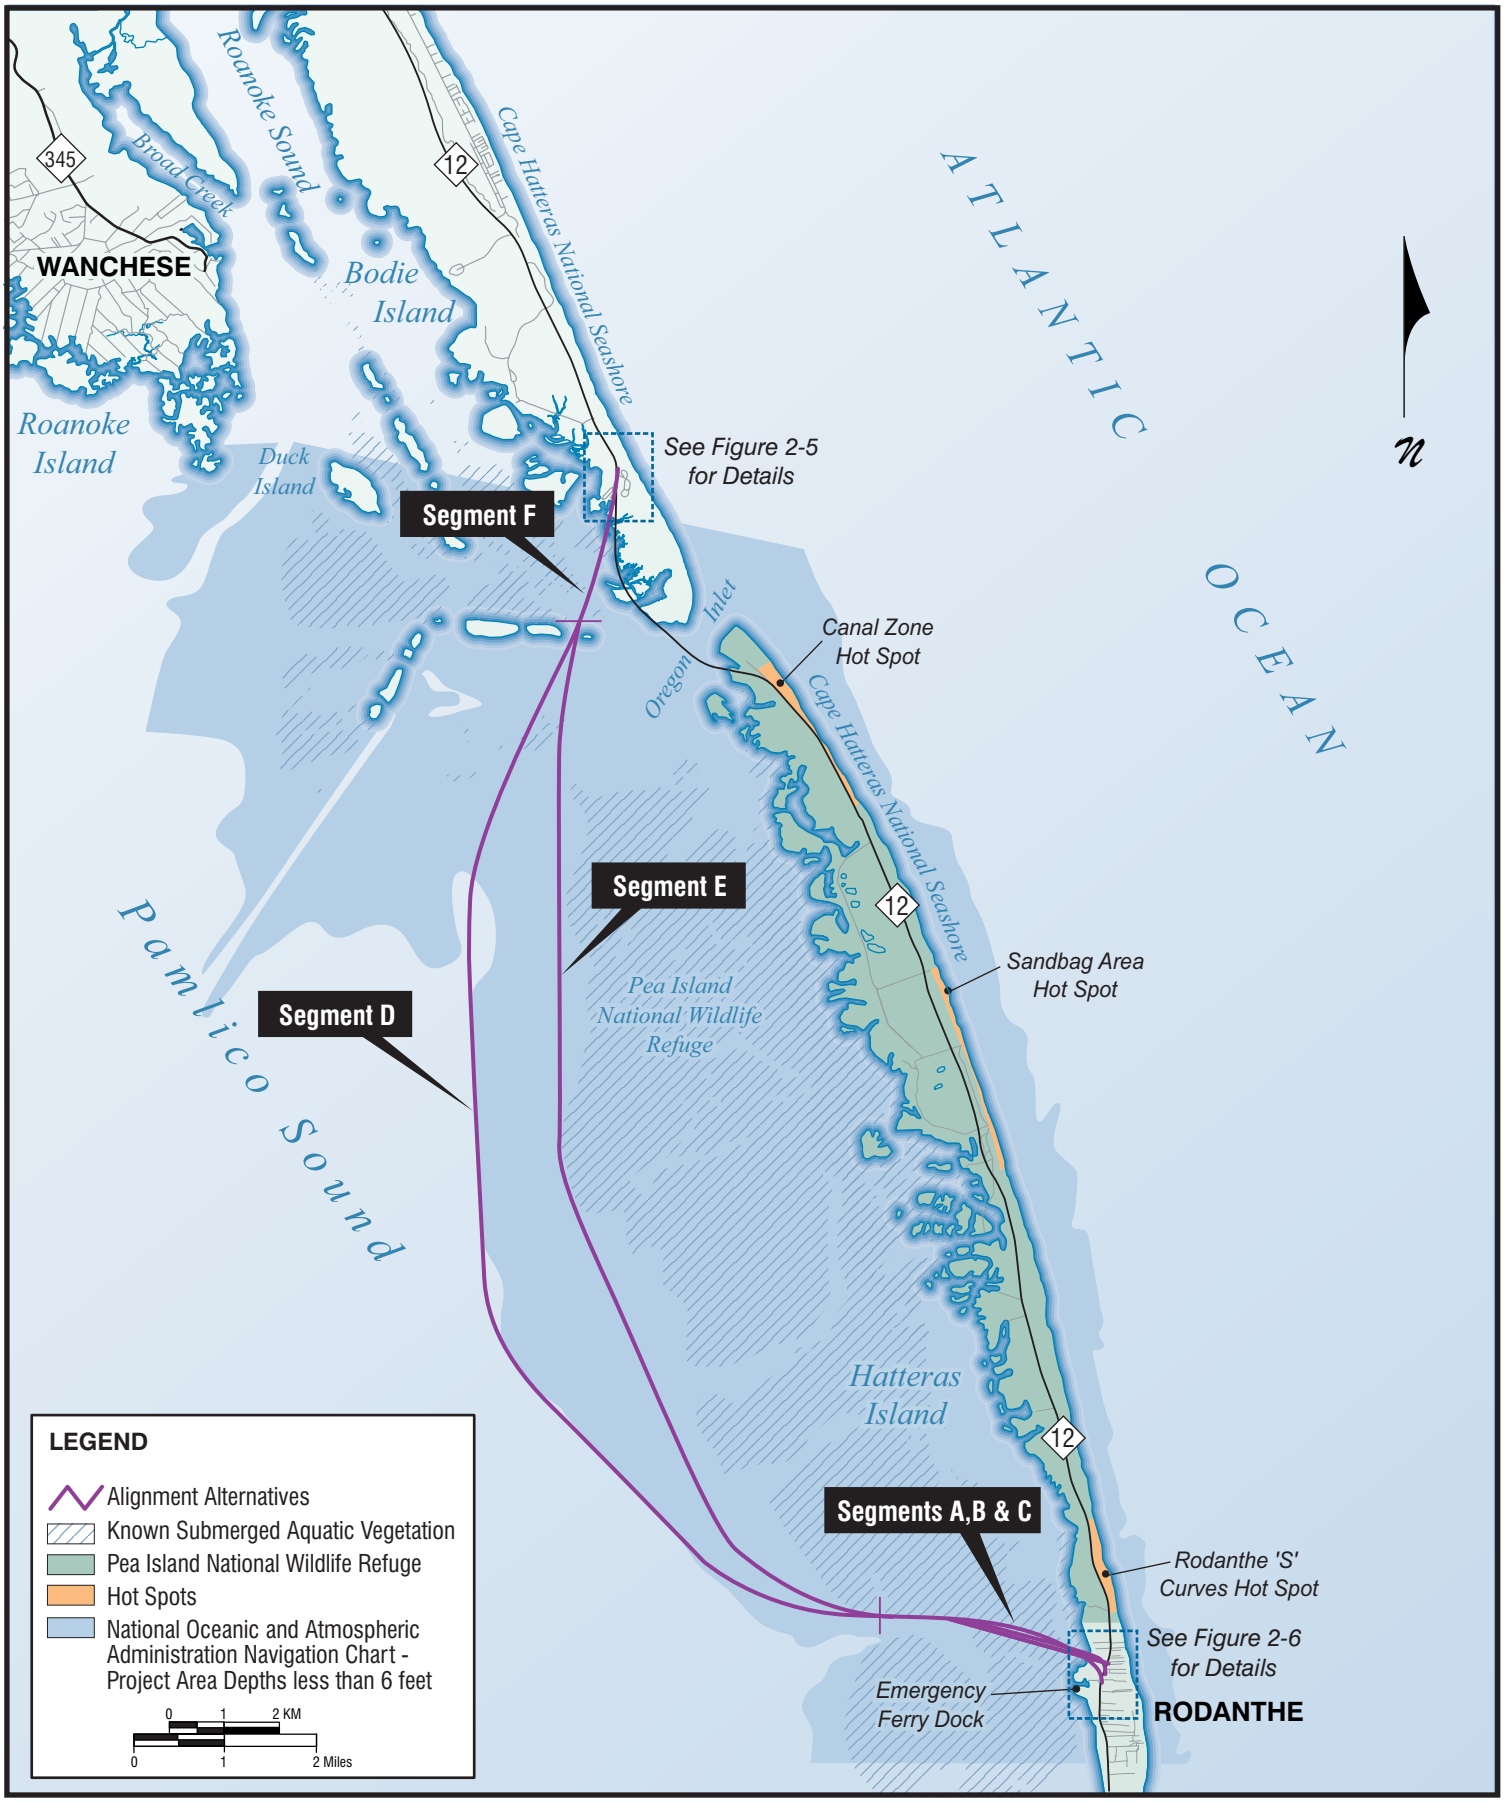
- The alignment connections to NC 12 must be potentially eligible to receive a non-impairment determination from the NPS;
- Selected alignments would minimize impacts to multiple natural resources, including SAV, wetlands, and federally protected species; and
- Selected alignments would minimize impacts to cultural resources and community features including historic properties, home and business displacements, scenic views, recreational opportunities, and public services to the maximum extent practicable.

2.4.2 Alignment Alternatives within the Pamlico Sound Bridge Corridor

All of the alignment alternatives within the Pamlico Sound Bridge Corridor terminate on Bodie Island near the US Coast Guard Station and Oregon Inlet Marina, approximately in the same location as the previous 1993 Parallel Bridge Corridor Alternative described in Section 2.2.5. There are two alignment alternatives for the portion of a replacement bridge in the open water of the Pamlico Sound and three Rodanthe terminus options. The alignment alternatives, labeled by segment, are shown in Figure 2-4. Termini locations are shown in more detail in Figure 2-5 and Figure 2-6.

2.4.2.1 Rodanthe Termini – Segments A, B, and C

Segments A, B, and C begin in Rodanthe. All three segments begin north of the emergency ferry dock.



Segment A is 1.9 miles (3.0 kilometers) long. It curves from the land and begins on existing NC 12 approximately 200 feet (61 meters) south of the Liberty service station.

Segment B also curves from the land and is 2.0 miles (3.2 kilometers) long. Segment B begins at existing NC 12 approximately 600 feet (183 meters) south of the Chicamacomico Life Saving Station.

Segment C is 1.8 miles (2.8 kilometers) long and is the northernmost Rodanthe alignment alternative. Segment C begins at existing NC 12 approximately 600 feet (183 meters) north of the Liberty service station. It has a straight approach, and it meets with existing NC 12 at a signalized intersection.

2.4.2.2 Pamlico Sound Open Water – Segments D and E

Segments D and E begin where Segments A, B, and C end. Both extend north through Pamlico Sound, bypassing the Pea Island National Wildlife Refuge. Segment D is 14.8 miles (23.8 kilometers) long and Segment E is 13.8 miles (22.1 kilometers) long. Segment E is within

2003 ALIGNMENT ALTERNATIVES

Figure 2-4

2003 BODIE ISLAND TERMINUS

Figure
2-5

2003 RODANTHE TERMINUS OPTIONS

Figure
2-6

Corridor Alternative 4, just outside of known SAV areas mapped by the NMFS and the DMF. Segment D is further west in areas mapped by the National Oceanic and Atmospheric Administration (NOAA) as having depths greater than 6 feet (1.8 meters). Segments D and E converge as they begin their approach to Bodie Island.

2.4.2.3 Bodie Island Termini – Segment F

Segment F begins where Segments D and E merge and ends just south of the entrance to the US Coast Guard Station and Oregon Inlet Marina. It is 1.3 miles (2.1 kilometers) long.

2.4.3 Evaluation Factors

The following resources were considered in the development of alignment alternatives:

- Community
  - Displacements
  - Views
  - Accessibility
  - Public services
  - Recreational use of Pamlico Sound
  - Traffic service at Rodanthe
- Natural Resources
  - Wetlands
  - SAV locations mapped by the NMFS and the DMF
- Cultural Resources
  - Historic properties
  - Underwater archaeology
- Coastal Conditions

Other factors considered included utility impacts, possible construction techniques, adequacy of traffic service provided, and the potential effect on known hazardous material or underground storage tank sites.

2.4.3.1 Community

Tourism is the principal industry in Dare County and on Hatteras Island. The tourist industry creates a large number of local jobs and generates substantial revenue for both Dare County and the State of North Carolina. Dare County promotes tourism during the peak season and the

development of "shoulder" season tourism (in the spring and fall) (Outer Banks Chamber of Commerce, 2001). Abundant natural resources will continue to be a major draw for tourists.

At the time of the study, the NPS web site showed total recreation visits to the Seashore in 2002 at more than 3.6 million. The Seashore is a popular local, state and national vacation destination. Visitors enjoy a variety of activities, including birding, fishing, surfing or wind boarding, swimming, hiking, and attending interpretive programs offered by NPS Rangers. Boating, fishing, wind boarding, and kite boarding are popular recreational activities within the project area.

The USFWS web site for the Refuge shows that it receives 2.7 million visitors annually, including people passing through the Refuge on NC 12, birders, canoeists, beach users, fishermen, and photographers (Pea Island National Wildlife Refuge web site, August 18, 2008).

The southern beaches on Hatteras Island are part of unincorporated Dare County and feature the six recreational-oriented communities of Rodanthe, Waves, Salvo, Avon, Buxton, and Frisco. Hatteras Village, a seventh community, is home to the Hatteras Inlet Ferry Terminal. Rodanthe, like the other communities on Hatteras Island, is experiencing growth. New home construction continues to supply an increasing demand for personal and rental recreational properties. New commercial properties to support the increasing use of the island are also emerging.

Products and services involved with daily life on Hatteras Island come across Bonner Bridge. The island relies heavily on repair and other services from the mainland. Residents (as well as visitors) of Hatteras Island rely on off-island community services. Telephone and electric service are brought to Hatteras Island via Bonner Bridge. See Section 3.1 for additional community information.

2.4.3.2 Natural Resources

The natural resource evaluation factors listed under Section 2.3.3 were assessed when evaluating the Pamlico Sound Bridge Corridor alignment alternatives. In addition, detailed data on wetlands, biotic communities, fisheries and wildlife resources, and protected species were collected and utilized in the alignment alternative evaluation process. (See Section 3.7)

The predominant wetland types crossed by the alignment alternatives are man-dominated, maritime shrub thicket, salt shrub/grassland, black needlerush, and smooth cordgrass (see Figure E-2a through Figure E-2h in Appendix E, which illustrate wetland locations and plant communities in the project area). Plant communities consist of primarily wetland communities and some upland maritime shrub-scrub and dune communities.

The USFWS lists 18 species for Dare County (as of February 11, 2003, the latest available at the time of this comparison of alternatives) that are federally threatened, endangered, or Federal species of concern. However, according to the USFWS, the Shortnose sturgeon should have been included on the USFWS list for Dare County as a federally endangered species. (It was added during the next update.) (Personal communication, April 2, 2004, Dale Suiter, USFWS Raleigh Field Office.) In addition, one species found in Dare County (the red wolf) was listed as experimental by the USFWS. Critical wintering habitat for the piping plover is designated on the shores of Oregon Inlet, both on the southern tip of Bodie Island and the northern tip of Hatteras Island. The Endangered Species Act of 1973 (16 USC 1531-1543) defines critical habitat as specific geographic areas that contain habitat features essential for the conservation of a threatened or endangered species. These areas may require special management considerations or protection. A critical habitat designation affects activities with federal involvement such as

federal funding or a federal permit. Federal agencies are required to consult with the USFWS on activities they carry out, authorize, fund, or permit that may affect critical habitat.

North Carolina Natural Heritage Program data show occurrences of Natural Heritage Elements—which include state and federally-listed threatened and endangered species as well as other important species—in the project area.

2.4.3.3 Cultural Resources

Archaeological studies indicate that the environment of the Outer Banks provides little of the stability necessary for good archaeological preservation. Based on historical background research, no sites related to human habitation or evidence of shipwrecks are known in the project area (Krivor, 2003). An underwater archaeological survey identified no potentially significant submerged cultural resources within the project area (Krivor, 2004). Letters from the State Historic Preservation Officer (SHPO) concurring with this finding are included in Appendix A.

The (former) Oregon Inlet US Coast Guard Station at the northern end of Hatteras Island is listed in the National Register of Historic Places (NRHP). It is owned by the State of North Carolina. The Pamlico Sound Bridge Corridor alternatives would be further away from the (former) Oregon Inlet US Coast Guard Station than Bonner Bridge and would not directly affect the Station. However, although the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge with these alternatives, the method of access to the Station could be something different than a paved road.

The Chicamacomico Life Saving Station, on the east side of NC 12 at Owens Road in Rodanthe, also is on the NRHP. Constructed in 1910, the Chicamacomico Life Saving Station is representative of the style of station erected for the US Life Saving Service during the late nineteenth and early twentieth centuries. It is owned by the private Chicamacomico Historical Association.

A Phase II Historic Architectural Survey recommends an area that includes four contributing houses, associated out-buildings, and the Chicamacomico Life Saving Station in Rodanthe in the Pamlico Sound Bridge Corridor be considered a National Register-eligible historic district (see Chapter 3, Section 3.4.1). This recommendation was affirmed by the SHPO in a letter dated September 17, 2003 (see Appendix A).

2.4.3.4 Coastal Conditions

From 1849 to 1989, Oregon Inlet has migrated southward approximately 2.2 miles (3.5 kilometers) and 2,070 feet (631 meters) landward (Joyner et al., 1998). Annual erosion rates from 1946 to 1989 are approximately 75 feet (22.9 meters) per year southward and 16 feet (4.9 meters) per year landward (Inman et al., 1989). In addition to Oregon Inlet migration, the inlet has alternated widening and narrowing in response to severe storms since its opening. Because of the continued inlet migration threatening the southern terminus of Bonner Bridge, a terminal groin was constructed in 1989 at the northern end of Hatteras Island. As a result, Hatteras Island migration has halted. However, Bodie Island has continued to exhibit both along-shore and cross-shore migration. The continued migration has resulted in changes in both inlet width and orientation (Moffatt and Nichol, 2003).

Like all active tidal inlets, Oregon Inlet requires periodic dredging to maintain a navigation channel. The current natural inlet gorge is 30 to 40 feet (9 to 12 meters) deep but is south of the primary navigation span on Bonner Bridge.

The rate of erosion of the Hatteras Island ocean shoreline accelerated in 1993 and has continued since then. Shoreline erosion and ocean overwash threaten to sever segments of the NC 12 roadway for several miles south of Bonner Bridge.

2.4.4 Pamlico Sound Bridge Corridor Alignment Alternatives Analysis

The alignment segments described in Section 2.4.2 can be combined into the following alignment alternatives:

- Alignment A – Segments F, D and A;
- Alignment B – Segments F, D, and B;
- Alignment C – Segments F, D and C;
- Alignment D – Segments F, E and A;
- Alignment E – Segments F, E and B; and
- Alignment F – Segments F, E and C.

A comparison of the alignment alternatives is shown in Table 2-5 and discussed below.

All alignment alternatives were considered similar in cost; therefore, cost was not a factor in the comparison of alignments. All of the alignment alternatives terminate on Bodie Island with Segment F. Wetlands were delineated at both the Bodie Island and Rodanthe bridge termini areas (see Figure E-2a through Figure E-2h in Appendix E). No wetlands would be filled to construct Segment F, although approximately 0.15 miles (0.24 kilometers) of wetlands would be bridged. It is estimated that there would be approximately 0.13 miles (0.21 kilometers) of SAV bridged by Segment F. There would be no residential or business displacements or historic property impacts associated with this segment.

The two segments over open water—Segments D and E—connect to Segment F at the southern end of Bodie Island and continue south in Pamlico Sound towards Rodanthe. Segments D and E are outside of areas of known SAV. Segment D, in depths of 6 to 7 feet (1.8 to 2.1 meters), is expected to require minimal dredging to float barges carrying bridge construction equipment and materials. Constructing Segment E, in shallower depths (3 to 4 feet or 0.9 to 1.2 meters), likely would necessitate more dredging to float construction barges than Segment D.

Differences among the three alignment alternatives for a replacement bridge terminus in Rodanthe (Segments A, B, and C) are evaluated in Sections 2.4.4.1 through 2.4.4.6.

2.4.4.1 Pamlico Sound Bridge Corridor Alignment Alternative A – Segments F-D-A

Alignment Alternative A begins at Segment F on Bodie Island, follows the more western, deeper Segment D in the Pamlico Sound, and curves onto land at Rodanthe where it terminates near the Liberty service station. During the alignment study, it was estimated that Alignment Alternative A would displace three homes. It also would displace a building adjacent to the service station that houses three commercial businesses: an auto repair shop, a restaurant, and a produce store.

Table 2-5. Pamlico Sound Bridge Corridor Alignment Alternatives Impact Comparison

Impacts	Alignment Alternatives Comparison					
	Alternative A (Segments F-D-A)	Alternative B (Segments F-D-B)	Alternative C (Segments F-D-C)	Alternative D (Segments F-E-A)	Alternative E (Segments F-E-B)	Alternative F (Segments F-E-C)
Estimated Total Length of Bridge in Miles (Kilometers)	18.0 (29.0)	18.1 (29.1)	17.9 (28.6)	17.0 (27.2)	17.1 (27.4)	16.9 (27.0)
Estimated Total Length of Bridge over Land in Miles (Kilometers)	Rodanthe 0.32 (0.51) Bodie Island 0.44 (0.70)	Rodanthe 0.45 (0.72) Bodie Island 0.44 (0.70)	Rodanthe 0.25 (0.40) Bodie Island 0.44 (0.70)	Rodanthe 0.32 (0.51) Bodie Island 0.44 (0.70)	Rodanthe 0.45 (0.72) Bodie Island 0.44 (0.70)	Rodanthe 0.25 (0.40) Bodie Island 0.44 (0.70)
Control of Access	Full	Full	Full	Full	Full	Full
Service Roads Locations	None[1]	None	None	None[1]	None	None
Utility Impacts[2]	Replace utilities on existing bridge and along NC 12					
Possible Construction Techniques	Mostly barge access	Mostly barge access	Mostly barge access	Mostly floating access with greater potential for construction -related dredging in Pamlico Sound	Mostly floating access with greater potential for construction -related dredging in Pamlico Sound	Mostly floating access with greater potential for construction -related dredging in Pamlico Sound
Adequate Level of Traffic Service at NC 12 Juncture in Rodanthe	Yes

Impacts	Alignment Alternatives Comparison					
	Alternative A (Segments F-D-A)	Alternative B (Segments F-D-B)	Alternative C (Segments F-D-C)	Alternative D (Segments F-E-A)	Alternative E (Segments F-E-B)	Alternative F (Segments F-E-C)
Known Archaeological Resources Affected	No					
Recreational Facilities Directly Affected	No					
Estimated Impact to submerged aquatic vegetation (SAV) in Miles (Kilometers)	1.52 (2.43)	1.52 (2.43)	1.44 (2.30)	1.52 (2.43)	1.52 (2.43)	1.44 (2.30)
Accommodates Channel and Island Movement	Yes					
Estimated Fill in Wetlands[4] in Acres (Hectares)	None	None	Total: 0.53 (0.21) Man Dominated - 0.36 (0.14); Maritime Shrub Thicket - 0.17 (0.07)	None	None	Total: 0.53 (0.21) Man Dominated - 0.36 (0.14); Maritime Shrub Thicket - 0.17 (0.07)
Wetlands Bridged in Miles (Kilometers)	Rodanthe 0.23 (0.37) Bodie Island 0.15 (0.24)	Rodanthe 0.18 (0.29) Bodie Island 0.15 (0.24)	Rodanthe 0.14 (0.22) Bodie Island 0.15 (0.24)	Rodanthe 0.23 (0.37) Bodie Island 0.15 (0.24)	Rodanthe 0.18 (0.29) Bodie Island 0.15 (0.24)	Rodanthe 0.14 (0.22) Bodie Island 0.15 (0.24)
Access to Pea Island National Wildlife Refuge (Refuge)	NC 12 will extend to Refuge Boundary; Refuge will provide some type of access within the Refuge.					
Affect Hazardous Material/Underground Storage Tank Sites[5]	Yes	Possibly	Possibly	Yes	Possibly	Possibly

[1] After the selection of Pamlico Sound Bridge Corridor Alignments A and C for additional study, detailed roadway design drawings were prepared and included right-of-way information. Displacements increased, particularly for Alignment A, when a service road was included during conceptual design to maintain access to all properties.

[2] The utility companies will decide how to replace their services currently on Bonner Bridge; there would be an opportunity to attach utilities to the proposed bridge.

[3] Properties less than 50 feet (15.2 meters) from the alignment centerline (excluding outbuildings) were considered to be displaced.

[4] It was assumed that the first 500 feet (152.4 meters) of the project at each end is on fill. The maximum fill height is 10 feet (3 meters).

[5] Alternative Alignments A and D terminate within 50 feet (15.2 meters) of the Liberty service station pumps. All of the alignment alternatives cross, or are within 50 feet (15.2 meters) of crossing, an area used to store old cars and car parts.

No wetlands would likely need to be filled for this alignment alternative; approximately 0.38 miles (0.61 kilometers) of wetlands would be bridged. Alignment Alternative A would cross an estimated 1.52 miles (2.43 kilometers) of SAV. This is similar to the amount of SAV that would be crossed by the other alignment alternatives.

2.4.4.2 Pamlico Sound Bridge Corridor Alignment Alternative B – Segments F-D-B

Alignment Alternative B begins at Segment F on Bodie Island and follows the more western, deeper Segment D in the Pamlico Sound. Alignment Alternative B curves onto land at Rodanthe, where it terminates south of the Chicamacomico Life Saving Station.

Alignment Alternative B would displace one residence and would cross an area that was used to store cars that are utilized for auto parts by the automobile repair business just north of the Liberty service station. It also is probable that this alternative would displace a commercial business at the end of the alignment. Alignment Alternative B would require the acquisition of land from the NRHP-eligible historic district in Rodanthe.

Along with Alignment Alternative E, this alternative would have the most substantial effect on the views from the homes on the Pamlico Sound of the alignment alternatives. No wetlands would likely need to be filled for this alignment alternative; approximately 0.33 miles (0.53 kilometers) of wetlands would be bridged.

2.4.4.3 Pamlico Sound Bridge Corridor Alignment Alternative C – Segments F-D-C

Alignment Alternative C also begins at Segment F on Bodie Island and follows the more western, deeper Segment D in the Pamlico Sound. Alignment Alternative C makes a straight approach and landfall at Rodanthe, ending at an intersection north of the Liberty service station. A potential benefit of this connection would be a reduction in the amount of right-of-way necessary for the new alignment between the new bridge and existing NC 12 in Rodanthe. A signalized intersection could be designed to provide an adequate level of service for NC 12 traffic.

With this alignment alternative, residential displacements may be avoided. Along with Alignment Alternative F, Alignment Alternative C would have the least substantial effect on views from homes on Pamlico Sound. Alignment Alternative C would cross the area used to store cars by the auto repair business. This alignment alternative would fill approximately 0.53 acres (0.21 hectares) of wetlands and bridge an additional 0.29 miles (0.47 kilometers) of wetlands. The amount of wetlands filled is based on the assumption that as much as the first 500 feet (152.4 meters) of each endpoint would be on fill, and the area filled would be 100 feet (30.5 meters) wide.

2.4.4.4 Pamlico Sound Bridge Corridor Alignment Alternative D – Segments F-E-A

Alignment Alternative D and its impacts are identical to Alternative A except this alternative follows the shallower Segment E in Pamlico Sound. This alternative would increase the probability of needing to dredge the sound bottom during construction.

2.4.4.5 Pamlico Sound Bridge Corridor Alignment Alternative E – Segments F-E-B

Alignment Alternative E and its impacts are identical to Alternative B except this alternative follows the shallower Segment E in Pamlico Sound. This alternative would increase the probability of needing to dredge the sound bottom during construction.

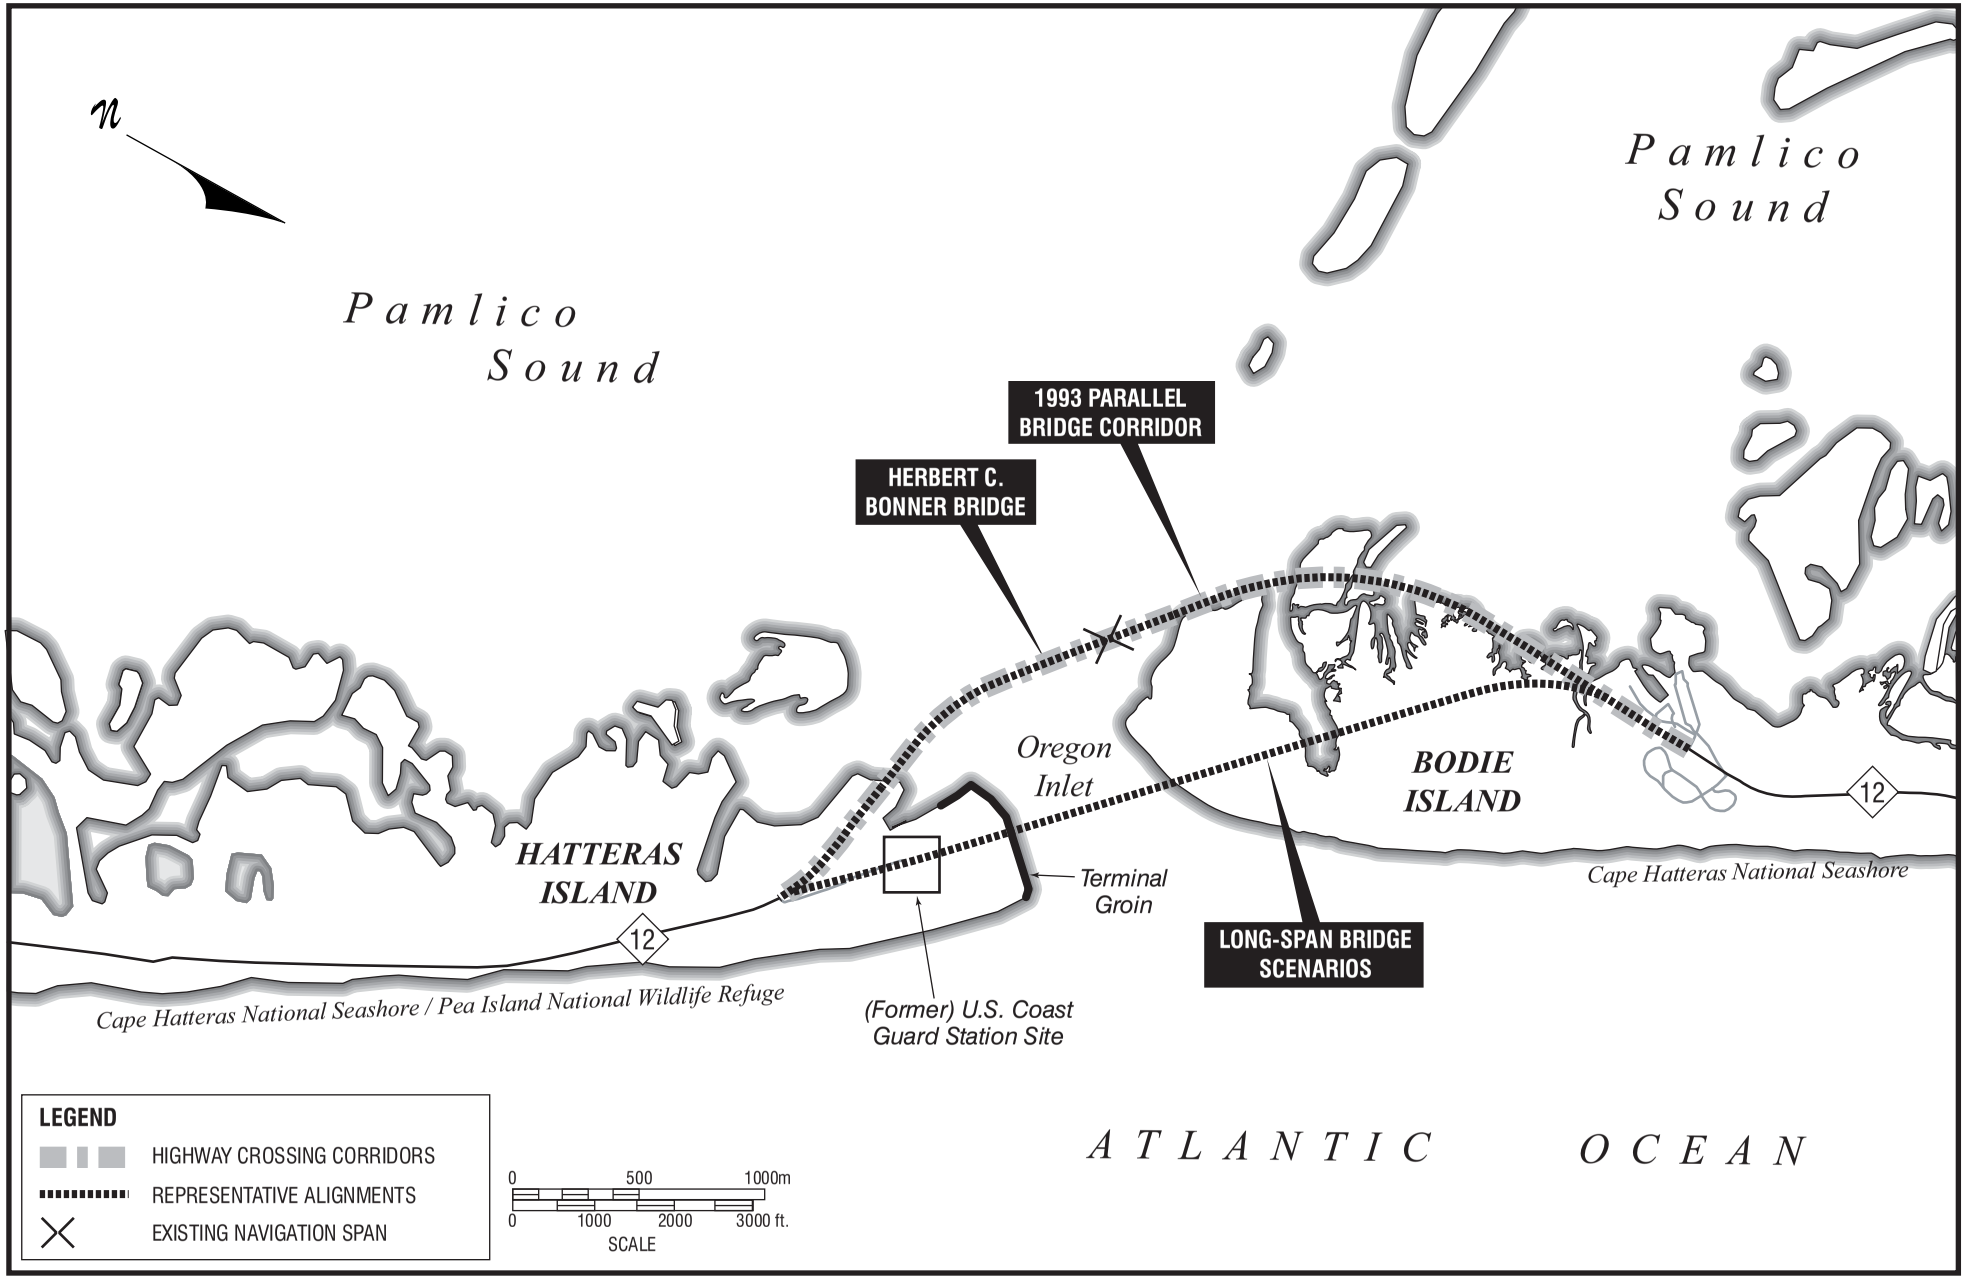
2.4.4.6 Pamlico Sound Bridge Corridor Alignment Alternative F – Segments F-E-C

Alignment Alternative F and its impacts are identical to Alternative C except this alternative follows the shallower Segment E in Pamlico Sound. This alternative would increase the probability of needing to dredge the sound bottom during construction.

2.4.5 Pamlico Sound Bridge Corridor Alignments Selected for Detailed Evaluation

On July 23, 2003, the NEPA/Section 404 Merger Team selected the Pamlico Sound Bridge Corridor Alignment Alternatives A (Segments F-D-A) and C (Segments F-D-C) for detailed evaluation in Chapter 4 of the FEIS (see Section 8.3.1.3). In the rest of the FEIS, Alignment Alternative A is referred to as the Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus, and Alignment Alternative C is referred to as the Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus.

Alternatives B (Segments F-D-B) and E (Segments F-E-B) were not carried forward because Segment B would require the acquisition of land from the NRHP-eligible historic district in Rodanthe. Segment B within these two alternatives also would likely affect the Chicamacomico Life Saving Station property, which is listed on the NRHP.



The NEPA/Section 404 Merger Team also did not select Pamlico Sound Bridge Corridor Alignment Alternatives D (Segments F-E-A) and F (Segments F-E-C) for detailed study, because Segment E is closer to shore and would require more dredging during construction of the bridge. This dredging could result in greater turbidity and greater SAV impacts than the other alternatives.

2.5 2004 Additional Replacement Bridge Scenarios

The Dare County Commissioners indicated concerns about the implementation of the Pamlico Sound Bridge Corridor, as selected for detailed evaluation in this FEIS by the NEPA/Section 404 Merger Team. Their concerns are:

- Continued road access to the full length of the Refuge, including the fishing area at the north end of Hatteras Island, would be threatened;
- If the replacement bridge is placed in a location where the groin is not required to maintain the southern bridge terminus, then the retention of the terminal groin could be jeopardized; and
- Funding for a replacement bridge within the Pamlico Sound Bridge Corridor was not fully secured at the time of the analysis. (See Section 2.12.4 on potential funding sources.)

The Dare County Commissioners prefer a replacement bridge that ends near the south terminus of Bonner Bridge and connects to existing NC 12. Specifically, they suggested to the NCDOT in early 2004 that the southern terminus of the replacement bridge be within a 10-acre (4-hectare) parcel that the State of North Carolina owns on the south side of Oregon Inlet, the site of the (former) Oregon Inlet US Coast Guard Station (see Figure 2-7). A replacement bridge ending at this location would pass over Refuge lands between the terminal groin and the State land (a

2004 ADDITIONAL REPLACEMENT BRIDGE SCENARIOS

Figure 2-7

distance of approximately 1,800 feet [549 meters]), thus avoiding a direct impact to Refuge lands. The Commissioners specifically asked in early 2004 that the NCDOT investigate suspension and cable-stayed structures. As with the alternatives considered in the 1993 DEIS, if a replacement bridge were constructed in this location, the NCDOT would have to take additional actions, such as beach nourishment or relocating NC 12, to maintain NC 12 between Oregon Inlet and Rodanthe.

In response to the Dare County Commissioners' concerns, five additional replacement bridge scenarios ending at the northern end of Hatteras Island were examined in early 2004. Four of these scenarios would terminate at the location suggested by the Commissioners. They differ by bridge span type (superstructure). These four scenarios are:

1. Multiple span cable-stayed bridge with the following spans on the main bridge: 750 feet - 1,800 feet - 1,800 feet - 1,800 feet - 1,800 feet - 750 feet (229 meters - 549 meters - 549 meters - 549 meters - 549 meters - 229 meters);

2. Single span cable-stayed bridge with the following spans on the main bridge: 1,800 feet - 4,000 feet - 1,800 feet (549 meters - 1,220 meters - 549 meters);

3. Suspension bridge with the following spans on the main bridge: 1,800 feet - 5,000 feet - 1,800 feet (549 meters - 1,524 meters - 549 meters); and

4. Multiple arch span bridge with the following spans on the main bridge: 270 feet-1,800 feet - 1,800 feet - 1,800 feet - 1,800 feet - 270 feet (82 meters - 549 meters - 549 meters - 549 meters - 549 meters - 82 meters).

The assumed location of these replacement bridge scenarios is shown in Figure 2-7. These four bridge scenarios would have main bridge spans with extended lengths; these are subsequently referred to as "long-span bridge scenarios." The longer spans allow the bridges to span the distance between the terminal groin and the State-owned land where they terminate. They also include long spans across Oregon Inlet. Both of these characteristics were requested by the Commissioners. The four long-span bridge scenarios were compared with a box girder bridge, with multiple navigation spans across Oregon Inlet, in the 1993 Parallel Bridge Corridor (i.e., the Preferred Alternative selected after the 1994 public hearings).

The fifth replacement bridge scenario considered was the combination of a box girder bridge in the Pamlico Sound Bridge Corridor and a connecting bridge between the Pamlico Sound Bridge Corridor and the northern end of Hatteras Island. This scenario also was compared with a bridge in the Pamlico Sound Bridge Corridor alone.

2.5.1 Construction Cost

The construction costs of the four long-span bridge scenarios and the 1993 Parallel Bridge Corridor are shown in Table 2-6 in 2003 dollars, current at the time this study was conducted.

Adding a connector from the north end of Hatteras Island to a Pamlico Sound Bridge Corridor bridge would cost an additional $58.4 million ($353.8 million instead of $295.4 million for a Pamlico Sound bridge alone) in 2003 dollars. The connector bridge and the Pamlico Sound bridge would intersect over Pamlico Sound to the northwest of Hatteras Island.

Table 2-6. Construction Cost Comparison of the Long-Span Bridge Scenarios and the 1993 Parallel Bridge Corridor

Replacement Bridge Scenario		Construction Cost (2003 dollars)[1]
Long-Span Bridge Scenarios	Multiple Span Cable-Stayed	$246,800,000
	Single Span Cable-Stayed	$363,100,000
	Suspension	$746,000,000
	Multiple Arch Span	$295,000,000
1993 Parallel Bridge Corridor (1993 Preferred Alternative)		$151,000,000

[1] Estimated bridge construction costs were presented in the memorandum *Cost Estimates for Bridges to the North End of Hatteras Island, TIP Project No. B-2500, Replacement of the Herbert C. Bonner Bridge (Bridge No. 11) over Oregon Inlet - Dare County, NC* (Parsons Brinckerhoff Quade & Douglas, Inc., May 20, 2004). Costs include approach roadway and bridge cost, as well as the main bridge cost.

The 1993 Parallel Bridge Corridor's costs are the final design costs of a box girder bridge in the 1993 Parallel Bridge Corridor (as discussed in Section 2.15), updated to 2003 dollars by the NCDOT for use in this comparison. These costs reflect either the bridge as described in Section 2.15, or a slightly shorter bridge that would end within the existing NCDOT easement at the northern end of Hatteras Island. The costs are the same because the cost savings associated with the shorter length of such a bridge would be offset by the higher construction costs associated with a temporary bridge erected to serve Bonner Bridge traffic while the new bridge is being built in Bonner Bridge's easement.

The main span cost estimates for the four long-span scenarios were prepared based on existing or planned similar bridges (Parsons Brinckerhoff Quade & Douglas, Inc., May 20, 2004). The costs for the approach roadway and bridges for the four long-span bridges were developed based on the per square foot cost of the 1993 Parallel Bridge Corridor bridge design. The average of the per-square-foot costs of the 1993 Parallel Bridge Corridor bridge and the 17.5-mile-long (28.2-kilometer) Pamlico Sound Bridge Corridor bridge were used to develop the cost for the approach roadway and bridge for the Hatteras Island connector to the Pamlico Sound Bridge Corridor bridge.

2.5.2 Comparison of Long-Span Bridges and 1993 Parallel Bridge Corridor

All four of these scenarios would accommodate the desires of Dare County Commissioners to have the replacement bridge terminating at the northern end of Hatteras Island. However, a box girder bridge in the 1993 Parallel Bridge Corridor would cost far less than any of the long-span bridges.

A new Oregon Inlet bridge in the 1993 Parallel Bridge Corridor could be designed and built so it would terminate within the state's existing NC 12 easement. No new NC 12 easement would be needed, so no Refuge compatibility determination would be needed for the south terminus of such a bridge. A compatibility determination would be needed for any long-term efforts to maintain NC 12 south of Oregon Inlet in areas where the maintenance activities would use Refuge lands outside the NC 12 easement (e.g., in areas where beach erosion threatens existing NC 12).

A long-span bridge would extend to the site of the state-owned (former) US Coast Guard Station by spanning over the sand accreted area behind the terminal groin that is Refuge land, thus also directly using only lands which the state has a right to use. However, by passing over Refuge land, these scenarios would be subject to a compatibility determination by the Refuge in order to get the necessary permits. This bridge alignment also would pass through a longer length of the Cape Hatteras National Seashore on Bodie Island, thereby increasing impacts to this resource rather than minimizing harm as is required by Section 4(f) of the Department of Transportation Act of 1966 (see Chapter 5).

Maintenance cost is an aspect that should be considered in the decision to implement any of the long-span bridge scenarios to the northern end of Hatteras Island. The NCDOT State Hydraulics Engineer has indicated that the selection of a location for the replacement of Bonner Bridge seaward of Bonner Bridge would subject a bridge to substantial adverse conditions associated with the dynamics of the deepwater inlet. The superstructures of the long-span schemes are invariably either all steel (in the case of the single span cable-stayed bridge and the suspension bridge) or composite steel/concrete designs (in the case of the multiple span cable-stayed bridge and multiple arch span bridge). Routine inspection, maintenance, and painting of the steel structural elements, especially where the superstructure is not too high above sea water, would need to be budgeted, scheduled, and diligently performed to ensure longevity of the structure.

2.5.3 Pamlico Sound Bridge Corridor with Hatteras Island Connector

The Pamlico Sound Bridge Corridor with a Hatteras Island Connector also would accommodate the desires expressed by most of the Dare County Commissioners to have a bridge alignment to the northern end of Hatteras Island. This bridge would twice cross the current navigation channel for Oregon Inlet, once with the connector and once with the replacement bridge in the Pamlico Sound Bridge Corridor. This bridge location also would affect the Refuge in a manner similar to the 1993 Parallel Bridge Corridor, including the retention of the terminal groin. It would add approximately $58.4 million (2003 dollars) to the construction cost of the Pamlico Sound Bridge Corridor. Without NC 12 maintenance, the connector bridge would eventually only serve the northern tip of Hatteras Island because NC 12 south of that point would be lost to future shoreline erosion (see Section 2.6.2.1).

2.5.4 Conclusion

Based on the above findings, the NCDOT dropped from further consideration the long-span bridge scenarios and the concept of a Pamlico Sound Bridge Corridor with a Hatteras Island Connector. The Pamlico Sound Bridge Corridor with the two termini options selected for detailed evaluation based on the studies described in Sections 2.3 and 2.4 remained the only alternatives under consideration. After further discussions with Dare County officials, the decision was made to revisit the Parallel Bridge Corridor but with the addition of a NC 12 maintenance component.

2.6 2005 Parallel Bridge Corridor with NC 12 Maintenance Alternatives Studies

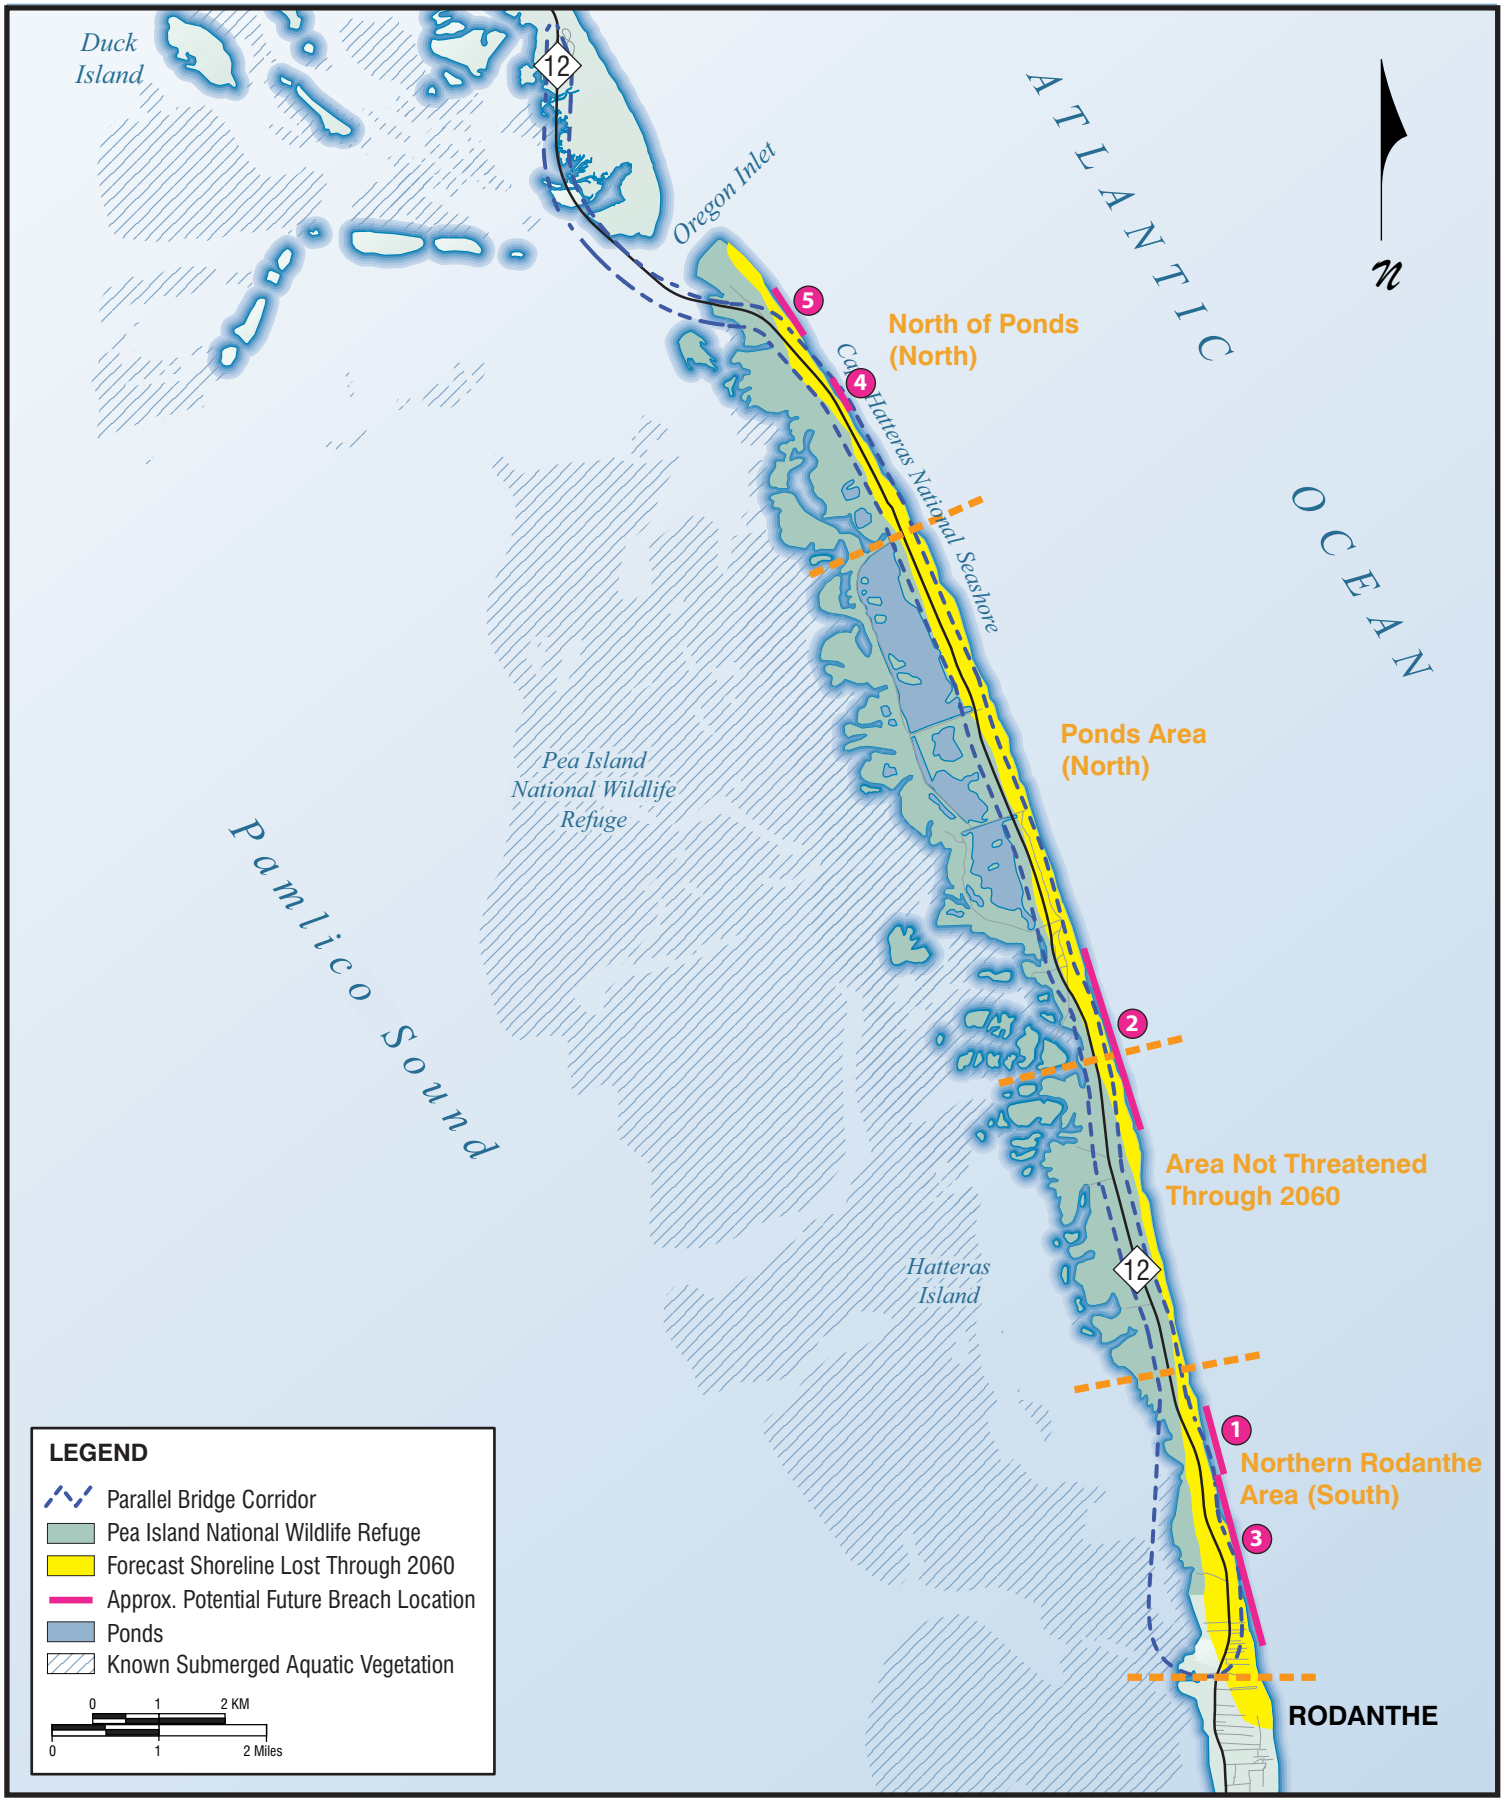
The October 13, 2004 NEPA/404 Merger Agreement defined the Parallel Bridge Corridor as consisting of two components: 1) an Oregon Inlet bridge to the west of the existing Bonner Bridge from the northern end of Hatteras Island to Bodie Island; and 2) an NC 12 maintenance

alternative designed to keep NC 12 between northern Rodanthe and Oregon Inlet open through 2060. The location of the Parallel Bridge Corridor is illustrated in Figure 2-8. The bridge over the Oregon Inlet was assumed to be that assessed in the 1993 DEIS, as modified in a subsequent bridge type study (1995) and final design development (1999), and including small alignment shifts at the bridge's southern terminus on Hatteras Island to accommodate the locations of various NC 12 maintenance alternatives, as well as 8-foot (2.4-meter) shoulders (as opposed to the 6-foot [1.8-meter] shoulders on the 1999 final design). The focus of the 2005 alternative study was on the NC 12 maintenance component.

There are several challenges associated with the development of a Parallel Bridge Corridor in conjunction with NC 12 maintenance, including the following:

- Coastal Erosion and Potential Breach Formation. There has been a high historic rate of shoreline erosion on parts of Hatteras Island to the north of Rodanthe, and much of NC 12 in the Refuge will be lost by 2060 if current trends continue. The potential exists for Hatteras Island within the Refuge to be breached by a storm.

- Existing NC 12 Easement. The existing NC 12 easement (or right-of-way) through the Refuge is 100 feet (30.5 meters) wide, and any improvements to NC 12 outside of the existing easement would require a Right-of-Way Permit from the USFWS.



- Wetlands. Most of the land within the Refuge to the west of NC 12 is wetland, so any road relocation on fill to the west could have substantial wetland impacts.

- Refuge Management Plan and Legal Requirements. Any use of lands within the Refuge must be found compatible with the Refuge's Management Plan (e.g., the Plan's goals and objectives) and establishing legislation, as per the National Wildlife Refuge System Improvement Act of 1997. In 2001, Refuge management gave a preliminary determination that the Oregon Inlet bridge in the Parallel Bridge Corridor alone "cannot be found compatible [with their Management Plan] and a Right-of-Way Permit cannot be issued." A Comprehensive Conservation Management Plan for the Refuge was under development at the time. The then current long-range management strategy for the Refuge is found in the 1980 *Pea Island National Wildlife Refuge Master Plan* and was subsequently adopted in July 2006.

- Disposition of the Terminal Groin. The permit granted for the construction of the terminal groin states that the groin's purpose is "to protect the southern segment of the existing Herbert C. Bonner Bridge." Therefore, the USFWS has indicated that a new permit for the groin would be needed if it were to be retained after the demolition and removal of Bonner Bridge. The new permit also would require a compatibility determination.

- Dare County Desire to Maintain Road Access to the Entire Refuge. Any approach to long-term NC 12 maintenance selected for implementation must address Dare County's concerns over maintaining road access to the Refuge, recognizing that other stakeholders do not have the same desire.

Multiple approaches to long-term NC 12 maintenance were evaluated during this study. Based on study findings and coordination with resource and regulatory agency representatives, three alternatives for long-term NC 12 maintenance within the Parallel Bridge Corridor were selected for evaluation in detail in this FEIS. They are:

PARALLEL BRIDGE CORRIDOR FEATURES

Figure 2-8

- Nourishment. Maintenance of NC 12 in the existing easement through beach nourishment with new dunes at several locations;

- Road North/Bridge South. NC 12 relocation to the west as a road in the northern half of the Refuge and on a bridge in the Rodanthe area; and

- All Bridge. NC 12 relocation to the west on a bridge both in the northern half of the Refuge (with Refuge access points) and in the Rodanthe area.

2.6.1 Study Process

2.6.1.1 Coastal Modeling

Coastal modeling was completed in 2004. The coastal modeling process involved developing an analytical procedure to estimate the probability that NC 12 would be "vulnerable" to shoreline erosion through 2060 between Oregon Inlet and Rodanthe. Vulnerable, in this context, means that NC 12 is likely to be exposed to flooding, overwash, or possible damage. Previous NC 12-related erosion studies (associated with several TIP projects considering short-term solutions to the threat to NC 12 of shoreline erosion on Hatteras Island) indicate that damage or overwash is minimized when a 230-foot wide (70.1-meter) buffer is maintained between the road and the ocean, sometimes in association with protective dunes. The future location of the coastline and the required buffer was estimated in 10-year increments from 2010 to 2060 and mapped. The forecast 2010 to 2060 high erosion shoreline locations (in 10-year increments) are shown in Appendix E in Figure E-1a through Figure E-1g. The anticipated 2060 high erosion shoreline is illustrated in Figure 2-8. The analysis assumed that the terminal groin would remain in place through 2060. In addition, the potential for a storm to cause a breach in Hatteras Island within the Refuge was reviewed.

2.6.1.2 Identification of Potential Detailed Study Alternatives

A series of three meetings was held in January 2005 (see Section 8.5.1) to select an initial set of potential alternatives for NC 12 maintenance through 2060 for the Parallel Bridge Corridor. At the first meeting (January 4), which included NCDOT staff, shoreline erosion contours overlaid on aerial photographs of the study area were presented. Potential alternatives for NC 12 maintenance were identified for comparison based on the shoreline erosion information and associated buffers, as well as rough unit cost information, the attendees' understanding of Refuge policies related to NC 12, wetland locations, and other potential stakeholder issues. Also, in order to allow for possibly "mixing and matching" (e.g. using nourishment in one location, and road relocation in another) different options, NC 12 was divided into four segments. These four segments, shown in Figure 2-8, are as follows:

1. Northern Rodanthe Area. From just north of Rodanthe to a point in Rodanthe where NC 12 will be unaffected by erosion in 2060;

2. Area Not Threatened Through 2060. From the southern end of the freshwater ponds to just north of Rodanthe;

3. Ponds Area. From the northern end of the Refuge's freshwater ponds to the southern end of the freshwater ponds; and

4. North of Ponds. From south of Oregon Inlet to the northern end of the Refuge's freshwater ponds.

The second meeting (January 6) included study team members and NCDOT management. The purpose of the meeting was to discuss and refine, as needed, the NC 12 maintenance alternatives that were identified for comparison at the previous meeting.

The third meeting (January 7) included study team members and environmental resource and regulatory agency representatives. The purpose of this meeting was again to discuss and refine, as needed, the general NC 12 maintenance alternatives that were identified for comparison terms at the two prior meetings. The alternatives selected for further consideration following the third meeting were:

- Beach nourishment north of ponds, the ponds area, and northern Rodanthe;

- Relocating NC 12 on a road 230 feet (70.1 meters) (the buffer width defined in Section 2.6.1.1) west of the 2060 high erosion shoreline north of ponds and the ponds area;

- Relocating NC 12 on a bridge at least 230 feet (70.1 meters) west of the 2060 high erosion shoreline north of ponds and the ponds area;

- Relocating NC 12 west of the freshwater ponds on or adjacent to the ponds' dikes in the ponds area;

- Relocating NC 12 on a bridge immediately west of Hatteras Island in northern Rodanthe; and

- In the near term, relocating NC 12 on a road 230 feet (70.1 meters) west of the 2020 high erosion shoreline in northern Rodanthe, and later relocating NC 12 on a bridge immediately west of Hatteras Island in this area.

2.6.1.3 Evaluation of Potential Detailed Study Alternatives

Engineered horizontal alignments were developed for the selected NC 12 maintenance alternatives that included relocating NC 12 on road or bridge. In addition, a beach nourishment program and dune requirements were developed for the beach nourishment alternative. The NC 12 maintenance alternatives were then evaluated and compared by segment using the following evaluation parameters:

- Total cost (i.e., capital cost along with operations and maintenance cost) and discounted cost through 2060;

- Sand requirements (for both dune construction and beach nourishment);

- Potential wetlands impact (both bridged and filled);

- Potential protected species impact;

- Effect on historic resources;

- Potential compatibility with Refuge management objectives;
- Effect on Refuge facilities (both direct and because of change in access to those facilities);
- Effect on Refuge use (both direct and because of change in access);
- Permits or statutory requirements;
- Long-term risk of additional cost or NC 12 disruption by a breach of Hatteras Island in the Refuge; and
- Displacements (homes and businesses).

The results of comparing the alternatives using the above criteria were tabulated for the Oregon Inlet bridge, the four NC 12 maintenance segments listed in Section 2.6.1.2, and representative combinations of NC 12 maintenance alternatives.

2.6.1.4 Selection of Detailed Study Alternatives

A second round of three meetings to select the Parallel Bridge Corridor alternatives with NC 12 maintenance to be evaluated in detail in the FEIS was held in late-March and early-April 2005. Once again, the first meeting in the series (March 22) consisted of the study team members, the second (March 31) meeting included NCDOT management, and the third meeting (April 4) included environmental resource and regulatory agency representatives. The evaluation and comparison of the potential detailed study alternatives was presented and discussed. These discussions formed the basis for the selection of the alternatives to be evaluated in detail in the FEIS, which are described in Section 2.6.4.

2.6.2 Coastal Studies

2.6.2.1 Shoreline Erosion

The methodologies used to determine coastal morphological change through 2060 included both long-term and short-term shoreline change assessments. Long-term shoreline change (including that associated with sea level rise) was determined from an analysis of shoreline position data spanning a 58-year period from 1946 to 2004. Linear trends were determined for 106 transects (shoreline location cross-sections) within the study area between northern Rodanthe and Oregon Inlet.

The highest erosion rates occur in the northern Rodanthe area with an average of 11 feet (3.4 meters) per year. In the ponds area, the average rate is 7 feet (2.1 meters) per year. For the area north of the ponds, the erosion rate is approximately 5 feet (1.5 meters) per year.

The prediction of future shoreline position assumes that the trend in the shoreline change from the historical data will continue until 2060. Because of the complex interactions that cause shoreline change, a high erosion future shoreline was assumed in developing alternatives for NC 12 maintenance through 2060 (see Section 3.6.3.1 for a discussion of the identification and definition of the 2060 high erosion shoreline). Sea level rise associated with past changes in shoreline position was reflected in the forecast. The influence of accelerated sea level rise on the forecasts is discussed in Section 3.6.3.3.

In addition, highway vulnerability to long-term erosion is defined as being susceptible to flooding and overwash when the distance from the edge-of-pavement to the active shoreline (i.e., the mean high water line) becomes less than or equal to 230 feet (70.1 meters) (i.e., the buffer width between the road and the ocean discussed in Section 2.6.1.1). This distance of 230 feet (70.1 meters) was added to the 2060 high erosion shoreline in order to establish the closest point to the ocean appropriate for NC 12 relocation alternatives.

The predicted 2060 high erosion shoreline is illustrated in Figure 2-8. The forecast 2010 to 2060 high erosion shoreline locations (shown at 10-year intervals) are illustrated in Figure E-1a through Figure E-1g in Appendix E.

2.6.2.2 Dune Requirements

The road elevation for NC 12 varies between 3 and 9 feet (0.9 to 2.7 meters) (North American Vertical Datum [NAVD], 1988) from Oregon Inlet to Rodanthe. Mean high water is approximately 1.2 feet (0.4 meter) NAVD. When the distance from the edge of NC 12's pavement to the active shoreline becomes less than or equal to the buffer width of 230 feet (70.1 meters), the vulnerability of NC 12 to short-term storm impacts can be mitigated by the presence of dunes. Dunes protect the highway by providing a physical barrier between the ocean and the highway during storm events that cause flooding and sand inundation from ocean overwash.

The potential for short-term shoreline change was quantified using a shoreline and dune erosion model called SBEACH to estimate the volumes of sand appropriate for protective dunes. The point at which NC 12 would become vulnerable because of the loss of protective dunes was determined; this point was based upon a statistical estimate derived from a suite of storms representing the last 100 years of hurricane activity. Vulnerability is defined as having greater than a 50 percent (plus or minus 5 percent) chance of losing 50 percent of a dune's volume in a 12-year period. Dunes would need to be replenished once 50 percent of their volume was lost to help ensure on-going road protection by the dunes. Based on the modeling, it was concluded for alternatives defined as including dunes that in the northern Rodanthe area, a dune 20 feet (6.1 meters) above grade should be built. In the ponds area and north of the ponds, a dune 10 feet (3.0 meters) above grade should be built for alternatives defined as including dunes.

High erosion rates combined with narrow island width in several locations correspond with potential breach locations (see the next section). The processes described above do not include potential along-shore and cross-shore changes that might occur if a breach forms, and the breach is allowed to remain open.

2.6.2.3 Potential Breach Locations within Pea Island National Wildlife Refuge

The information on potential breach locations in the Refuge used in this study is based on a draft product of the ongoing East Carolina University, US Geological Survey, and NC Geological Survey sponsored Coastal Cooperative Research Program that has been intensively studying the northeastern North Carolina coastal system since 2000. There are five potential breach locations within the Refuge (see Figure 2-8). The word breach is used rather than the word inlet because, if a breach were to occur it would likely close eventually (although not necessarily immediately) and likely would not become a long-term phenomenon like Oregon Inlet. The characteristics of these breaches are described in Section 3.6.3.4. Based on the opinions of an expert panel (whose findings are also described in Section 3.6.3.4), the southern end of the Pea Island National Wildlife Refuge would be the most likely location for a breach to occur.

2.6.3 Evaluation of Potential Detailed Study Alternatives

The potential detailed study alternatives identified in January 2005 and listed in Section 2.6.1.2 were evaluated according to the criteria listed in Section 2.6.1.3 both by the four project segments listed in Section 2.6.1.2, and in representative combinations of the segments (i.e., combinations that would provide a complete Parallel Bridge Corridor Alternative). The representative combinations allowed decision-makers and reviewers to consider the total impact of complete alternatives, but the segment results were prepared so that other potential combinations could also be considered as needed. The results were documented in the *Parallel Bridge Corridor Alternatives Report* (Parsons Brinckerhoff Quade & Douglas, Inc., 2005). This section describes the representative combinations, the design assumptions, the data used in the evaluation, and the evaluation results.

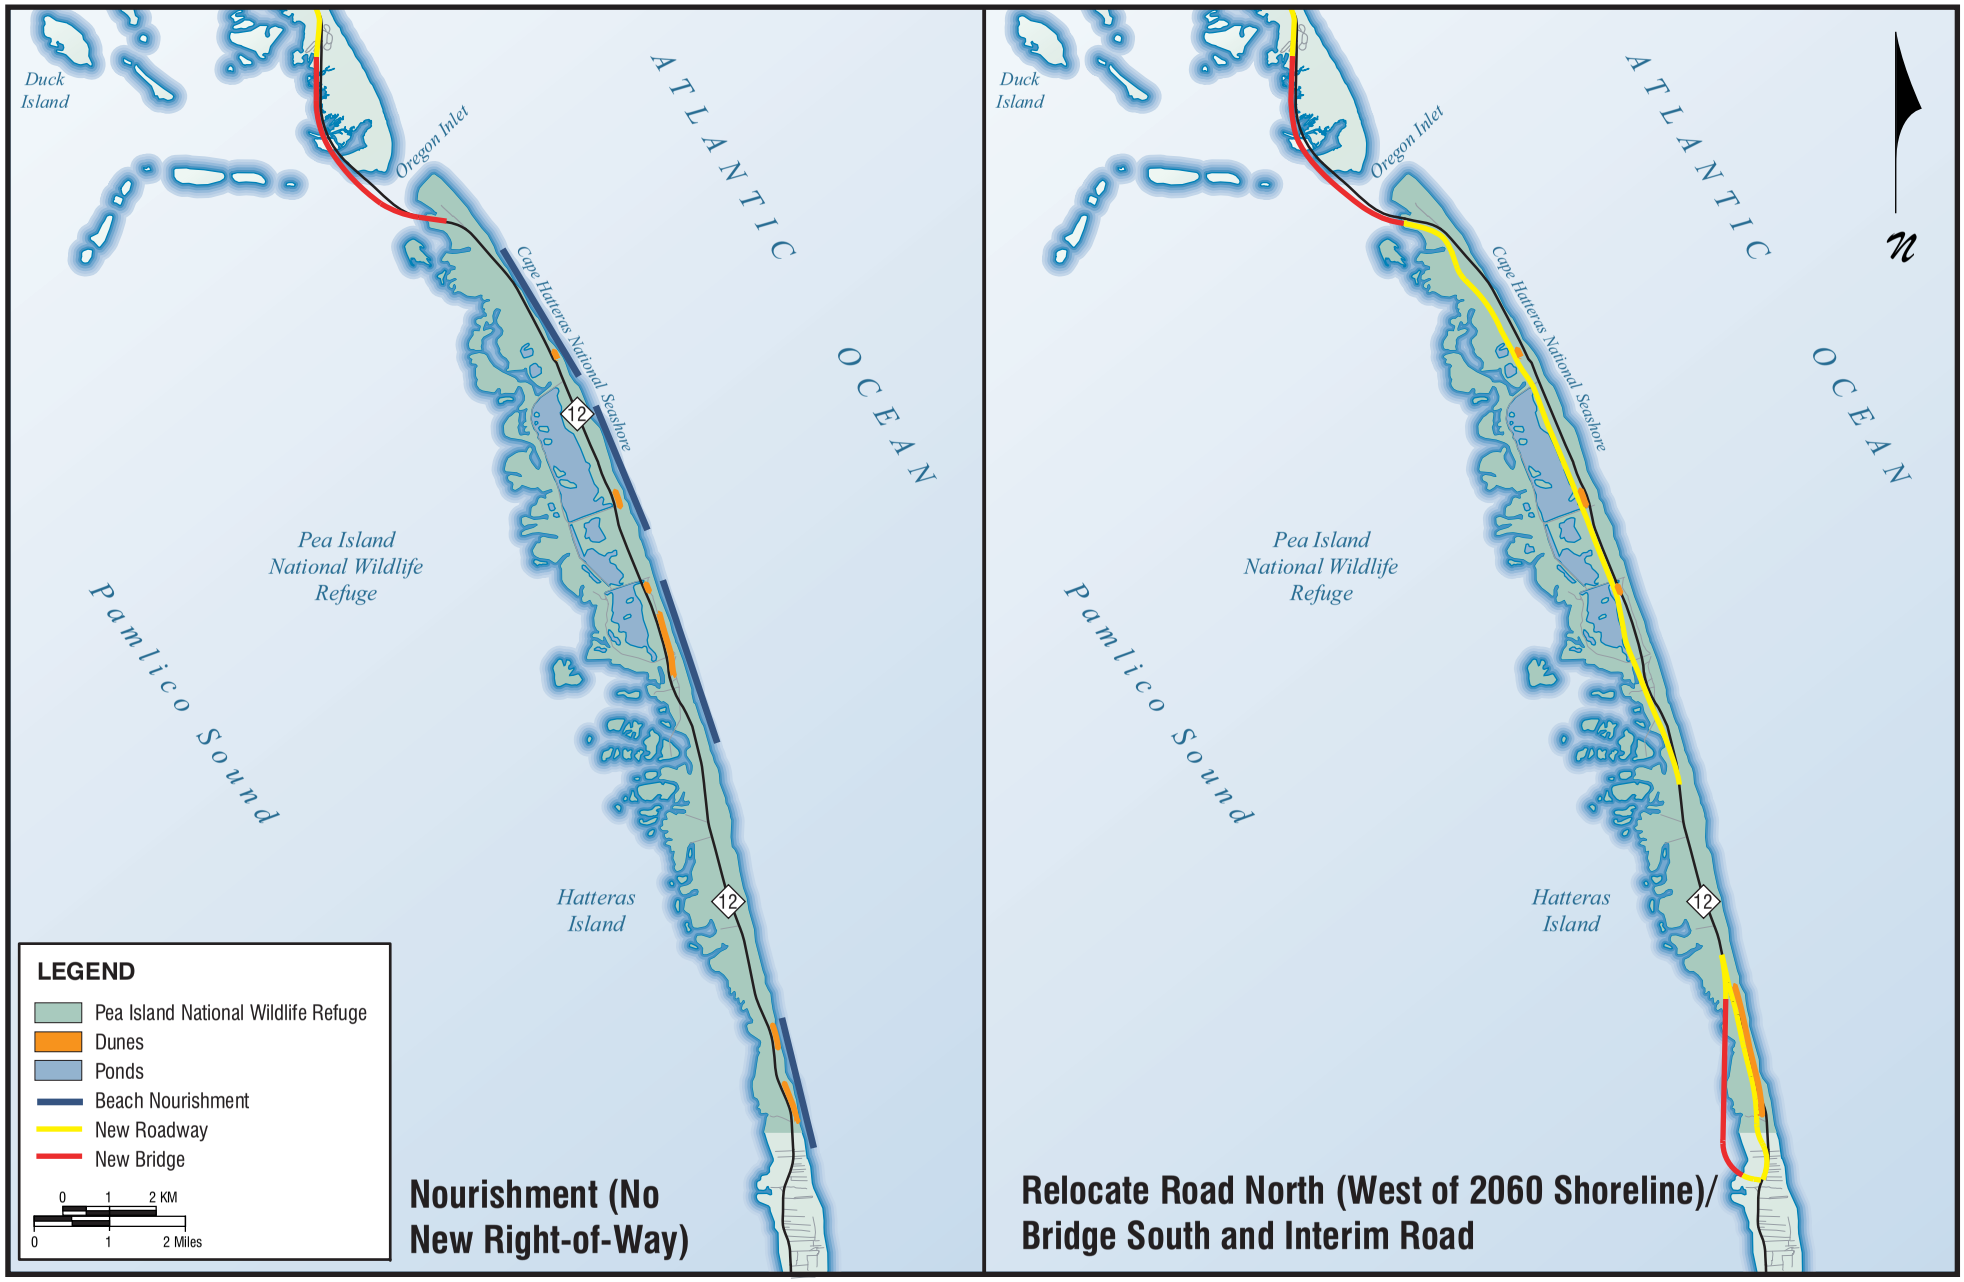
2.6.3.1 Representative Combination Alternatives

Six representative combinations of the NC 12 maintenance alternative segments were presented and discussed at the late-March and early-April 2005 meetings and are described in this section. They all include an Oregon Inlet bridge located immediately west of Bonner Bridge, as well as an approach to NC 12 maintenance from Oregon Inlet to northern Rodanthe through 2060. The locations of the various components of these alternatives are shown in Figure 2-9a and Figure 2-9b. The six representative combinations are:

Nourishment

This alternative consists of maintaining NC 12 in its current location through beach nourishment, which would be sufficient to provide at least the 230-foot (70.1-meter) buffer between the shoreline and NC 12. New dunes would protect NC 12 from overwash at several locations.

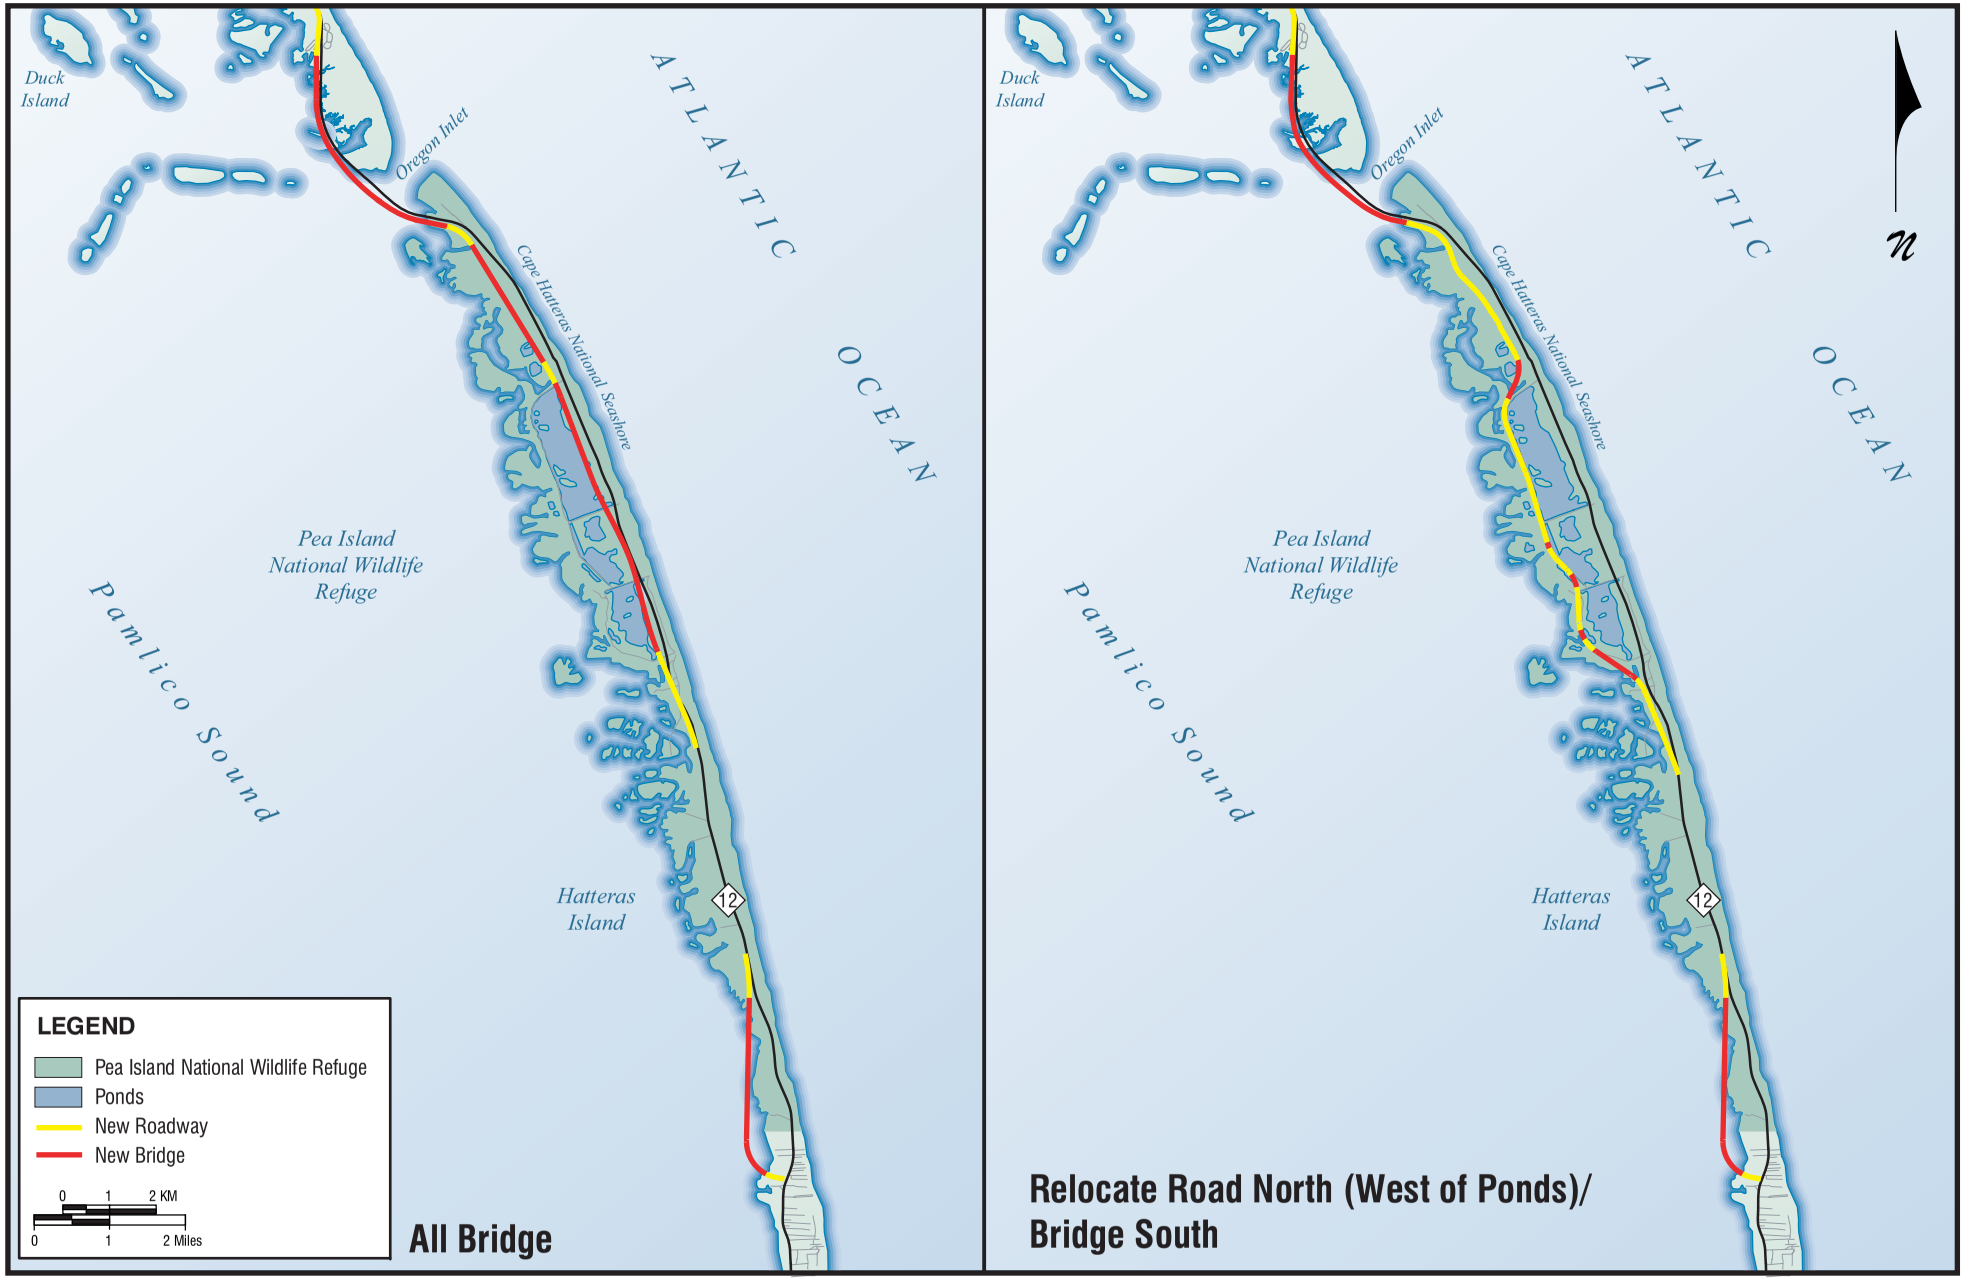
Nourishment North (No New Right-of-Way)/Bridge South



This alternative is the same as the Nourishment (No New Right-of-Way) Alternative except in the northern Rodanthe area. In the northern Rodanthe area, NC 12 would be relocated on an approximately 2.2-mile (3.5-kilometer) long bridge west of Rodanthe in Pamlico Sound that would rejoin existing NC 12 near the emergency ferry terminal in Rodanthe. The bridge would eliminate beach nourishment as an NC 12 maintenance strategy in an area where it would be the most extensive and where the availability of sand for nourishment is less certain. As noted in Sections 2.6.2.1 and 2.6.2.3, it is in the southern end of the Refuge and in the northern Rodanthe area where the forecast rate of erosion, as well as the potential for a breach to occur during a storm is the greatest.

Relocate Road North (West of 2060 Shoreline)/Bridge South

This alternative would relocate NC 12 on fill approximately 230 feet (70.1 meters) to the west of the predicted 2060 high erosion shoreline from Oregon Inlet to just south of the Refuge's freshwater ponds. Three new dunes would be built. This alternative also includes the bridge described for the previous alternative in the northern Rodanthe area. (This alternative is the same as the alternative shown in the second panel of Figure 2-9a but without the interim road relocation.)



Relocate Road North (West of Ponds)/Bridge South

This alternative would relocate NC 12 on fill approximately 230 feet (70.1 meters) to the west of the predicted 2060 high erosion shoreline to the north of the Refuge's ponds, then along the existing dikes to the west of the ponds, before connecting back into existing NC 12 just south of the ponds. The relocated road to the west of the ponds would be mostly on top of the dikes, but several structures also would be needed in order to avoid introducing sharp curves. This alternative also includes the bridge described previously in the northern Rodanthe area.

POTENTIAL PARALLEL BRIDGE CORRIDOR ALTERNATIVES

Figure 2-9a

POTENTIAL PARALLEL BRIDGE CORRIDOR ALTERNATIVES

Figure 2-9b

Relocate Road North (West of 2060 Shoreline)/Interim Road then Bridge South

This alternative is the same as the Relocate Road North (West of 2060 Shoreline)/Bridge South Alternative as far south as the northern Rodanthe area. This alternative would then include relocating NC 12 to approximately the buffer width of 230 feet (70.1 meters) to the west of the forecast 2020 shoreline, with dune protection, as an interim measure to delay the expenditure of costs associated with the Rodanthe area bridge described above. The Rodanthe area bridge then would be built by 2020.

All Bridge

This alternative would relocate NC 12 on bridge to the west of the predicted 2060 high erosion shoreline between Oregon Inlet and just south of the Refuge's ponds. Access to the Refuge would be provided at Oregon Inlet, just north of the Refuge's ponds, and south of the ponds. This alternative also would use the Rodanthe area bridge.

2.6.3.2 Design Assumptions

Roads and Bridges

A horizontal alignment was developed for each NC 12 maintenance road and bridge alternative. The design criteria used are shown in Table 2-7. A constant footprint width of 90 feet (27.4 meters) was assumed for the road alternatives. The cost estimates, in 2005 dollars, were based on experience with other similar highway construction projects. The period used for operation and maintenance costs was through 2060.

Table 2-7. Design Criteria

	Oregon Inlet Bridge	NC 12 Roadway	NC 12 Bridge
Design Speed	60 mph (96.6 kph)	60 mph (96.6 kph)	60 mph (96.6 kph)
Max. Superelevation	6%	8% max super chart (AASHTO)	6%
Lane Width	12 feet (3.6 meters)	12 feet (3.6 meters)	12 feet (3.6 meters)
Shoulder Width	8 feet (2.4 meters)	8 feet (2.4 meters) (4 feet [1.2 meters] paved plus 4 feet [1.2 meters] earth on 8%)	8 feet (2.4 meters)
Bridge Width (Gutter to Gutter)	40 feet (12.2 meters)	N/A	40 feet (12.2 meters)
Max. Grade	3.5%	5.0%	3.5%
Max. Side Slopes	N/A	3:1	N/A
Max. Degree of Curve	Degree of curve should not cause superelevation to exceed 6% on any bridge	Minimum radius of 1,200 feet (365.9 meters)	Degree of curve should not cause superelevation to exceed 6% on any bridge

The Oregon Inlet bridge for the Parallel Bridge Corridor was assumed to have predominantly the same alignment and design features as a final design for the bridge developed in 1999; however, the design used in this analysis varied in two ways from the 1999 final design. First, the alignment was altered as needed at the Hatteras Island terminus to meet the relocated NC 12 alternatives. Second, a concept for ending the new bridge in the same right-of-way as Bonner Bridge was developed. Finally, 8-foot (2.4-meter) shoulders were assumed on the new Oregon Inlet bridge, as opposed to the 6-foot (1.8-meter) shoulders on the 1999 final design. Figure 2-10 shows the three alternative alignments for the Hatteras Island terminus of the Oregon Inlet bridge. For the alignment that ends in the existing easement, it is assumed that the new bridge would be built over the top of the old bridge for its last two or three spans. A temporary detour road would be necessary for a short distance south of Bonner Bridge so that the new bridge could be built in the existing easement. There would be no difference in cost and minimal difference in impacts between these two easement assumptions. Building the southern terminus of the new bridge in the existing easement would complicate the construction process.

The cost estimates for the Oregon Inlet bridge were based on the 1999 estimate revised to take into account the changes at the southern end, then escalated to 2005 dollars.

The bridges on Hatteras Island and the bridge at northern Rodanthe were assumed to have characteristics similar to the Pamlico Sound Bridge Alternative, including driven precast piles to support the bridge (substructure). Cost estimates assumed an average cost per square foot of deck, experience on other similar bridge construction projects, and 2005 dollars.

Beach Nourishment

The beach nourishment alternatives assume that NC 12 remains in its current location and beach nourishment (plus dune enhancement) would be used to maintain an adequate beach and dune system: 85 to 140 feet (25.9 to 42.7 meters) of beach and berm, 60 to 120 feet (18.3 to 36.6 meters) of dune base, and a 25-foot (7.6-meter) clearance to the edge of pavement. Dune sizes were noted in Section 2.6.2.2. Long-term erosion rates based on linear regression were used to determine the amount of fill required to build and maintain the beach to this design level. The key assumptions included:

- The minimum beach nourishment project length along the beach would be 5,000 feet (1,524 meters) with 500-foot (152.4-meter) tapers (transition from nourished beach to beach that does not require nourishment) on each side;
- Average erosion rates for the area to be nourished were used within each NC 12 maintenance segment;
- An erosion rate factor (the ratio of the faster erosion rates associated with nourished beaches and historic beach erosion rates) of 1.5 to 3.0 was applied;
- The depth of closure would be approximately 30 feet (9.1 meters) (sand used in nourishment when it is eroded by the ocean will not transport beyond the point where the ocean depth is 30 feet [9.1 meters]) and the berm (dry beach) height would be 7 feet (2.1 meters) above mean sea level;
- Nourishment projects would be renourished every four years; and
- Sand used would be suitable for nourishment from the perspective of minimizing natural resource impacts.

OREGON INLET BRIDGE ALTERNATIVES

Figure 2-10

With this design, for each segment of NC 12 there remains a location for which the road is within 230 feet (70.1 meters) of the current shoreline at the end of each 4-year nourishment cycle.

2.6.3.3 Evaluation Data Used

The evaluation data used to compare the Parallel Bridge Corridor alternatives was derived from a variety of sources. The data used was data readily available and was considered sufficient for the selection of detailed evaluation alternatives. This section describes the data used.

Cost

Capital cost estimate assumptions are described in Section 2.6.3.2. Roadway operation and maintenance costs through 2060 were obtained from the NCDOT Division 1 Office, which is responsible for road maintenance in the study area. Bridge operation and maintenance costs were obtained from NCDOT's Bridge Management Unit. Right-of-way costs were developed by the NCDOT's Right-of-Way Branch for Division 1 based on the horizontal alignments described in Section 2.6.3.2.

Both total and total-discounted capital, operation and maintenance, and right-of-way costs were calculated. Costs for new roads, bridges, dunes, and nourishment from 2007 to 2010 (the year in which the Oregon Inlet bridge was at that time assumed to be opened) were categorized as capital costs, whereas subsequent costs were categorized as operation and maintenance costs.

Costs were discounted using a discount rate of 5 percent (FHWA, 1998). Discounting is often done when comparing alternatives whose streams of expenditures are notably different. For example, for the road and bridge alternatives, most of their costs are expended in the first four years of the analysis period (2007 to 2010). With the nourishment alternatives, however, costs are spread out throughout the period through 2060.

Discounting recognizes that benefits and costs do not always take place in the same period. When they do not, consideration should be given to when they actually do occur because benefits or costs that occur sooner are generally considered more valuable. In addition, current consumption is more expensive than future consumption, since an expected return on investment is being given up by consumption today. While a benefit-cost analysis was not done for this alternatives study, it can be assumed that keeping NC 12 open will result in a stream of benefits through 2060 that would be nearly identical for all of the Parallel Bridge Corridor alternatives.

When the cost streams for the various alternatives are discounted, the costs of alternatives with higher up-front expenditures (e.g., bridges) drop the least, and the costs of alternatives with expenditures spread-out through 2060 (e.g., nourishment) drop the most. With the latter, the costs are occurring closer to the time in which the benefits to the traveling public actually occur. Constant dollars are always used when discounting.

Sand Requirements

Sand availability and assumptions related to the estimated sand requirements for dunes and nourishment are described in Section 2.6.3.2.

Wetlands

The best wetland information available was used to estimate wetland impacts. This represented a combination of delineated wetlands (known primarily from the ocean to a point 300 to 500 feet [91.5 to 152.4 meters] west of NC 12), determined wetlands (primarily in the Rodanthe area), and

wetlands identified in the State of North Carolina's Geographic Information Systems (GIS) database and developed by the NCDENR Division of Coastal Management.

Protected Species

Preliminary biological conclusions on the potential for adversely affecting protected species were developed based on federally protected species listings for Dare County and the characteristics of the habitat in the study area.

Historic Resources

Historic resources listed on or eligible for inclusion in the NRHP were identified and approved by the SHPO during the impact evaluation for the Pamlico Sound Bridge Corridor in 2003 and 2004.

Refuge Facilities/Permits and Statutory Limits

Refuge facilities and the characteristics of their use were identified from aerial photography and other mapping, field observation, and conversations with Refuge staff. Permits and statutory limits were identified during past studies in the project area and communications with the agencies responsible for issuing the permits and enforcing the statutes.

Long-Term Risks

Information related to the potential for faster erosion than forecast and a storm-caused breach in the Refuge was developed during the coastal modeling described in Section 2.6.2.

Displacements

Displacement counts were developed by the NCDOT's Right-of-Way Branch based on the horizontal alignments described in Section 2.6.3.2.

2.6.3.4 Evaluation Results

The comparison of the representative combinations of Parallel Bridge Corridor alternatives for cost, sand requirements, and wetland use is presented in Table 2-8. The information presented includes an Oregon Inlet bridge located immediately west of Bonner Bridge and an approach to NC 12 maintenance from Oregon Inlet to northern Rodanthe through 2060. The alternatives also were compared from three additional perspectives: legal factors, risk, and other environmental factors. These comparisons are presented in the paragraphs that follow.

Cost

The costs in Table 2-8 include both the cost of the Oregon Inlet bridge and the NC 12 maintenance component listed in the heading. As shown in Table 2-8, beach nourishment is the most expensive alternative at $644.0 million. When discounted using the 5 percent discount rate, nourishment becomes much closer in cost but is still more expensive than the other Parallel Bridge Corridor alternatives; however, as will be seen in Section 2.12, it would be less than the Pamlico Sound Bridge Corridor alternatives. Alternatives with lower discounted costs could be viewed as providing a better return on the investment of state resources.

Relocating NC 12 as a roadway on fill in the northern part of the Refuge is the least expensive solution with the combined cost of the Oregon Inlet bridge, the road relocation, and a bridge at Rodanthe being $285.4 million. The cost of using the bridge at Rodanthe along with nourishment in the northern half of the Refuge is substantially less than the alternatives that use nourishment exclusively.

Table 2-8. Comparison of Cost, Sand Requirements, and Wetland Use for Representative Combinations

Factor	Parallel Bridge with NC 12 Maintenance					
	Nourishment	Nourishment North / Bridge South	Relocate Road North (West of 2060 Shoreline) / Bridge South	Relocate Road North (West of Ponds) / Bridge South	Relocate Road North (West of 2060 Shoreline) / Interim Road then Bridge South	All Bridge
Cost in 2005 dollars						
Capital Cost (2007-2010)	$222,500,000	$251,907,000	$271,300,000	$296,700,000	$242,700,000	$358,900,000
Capital Cost (2011-2060) and O&M Cost (2007-2060)	$421,500,000	$187,543,000	$14,100,000	$11,200,000	$67,100,000	$7,000,000
TOTAL Cost	**$644,000,000**	**$439,450,000**	**$285,400,000**	**$307,900,000**	**$309,800,000**	**$365,900,000**
TOTAL Discounted Cost (5% discount rate)	$312,100,000	$268,374,000	$232,800,000	$253,600,000	$235,700,000	$305,100,000
Sand Requirements in cubic yards (cubic meters) to 2060						
Dunes	1,033,300 (790,015)	166,600 (127,375)	155,600 (118,965)	0	377,800 (288,849)	0
Beach Nourishment	45,600,000 (34,863,700)	18,050,000 (13,800,220)	0	0	0	0
TOTAL	**46,633,300 (35,653,715)**	**18,216,600 (13,927,595)**	**155,600 (118,965)**	**0**	**377,800 (288,849)**	**0**
Wetlands Affected in acres (hectares)						
Wetlands Filled	3.6 (1.5)	1.8 (0.7)	67.5 (27.3)	32.3 (13.1)	76.4 to 79.4 (30.9 to 32.1)	8.5 (3.4)
Wetlands Bridged	0.2 (0.1)	1.4 (0.6)	1.6 (0.6)	6.2 (2.5)	1.6 (0.6)	25.8 (10.4)

Sand Requirements and Sources

Table 2-8 shows that large sand requirements are associated only with the beach nourishment component of the nourishment alternatives. If nourishment and dunes are the sole form of NC 12 maintenance, nearly 40 percent of the sand required through 2060 is associated with the nourishment of beaches in northern Rodanthe. A sand source near the north end of Hatteras Island, as well as sand from Oregon Inlet dredging, could be used for beach nourishment in the northern part of the Refuge. Sand from annual Oregon Inlet dredging alone would meet the forecast nourishment needs in the northern part of the Refuge. A sand source also is off the coast near Rodanthe, but its quality, quantity, and suitability are not adequately known.

Any nourishment program will need to consider the effect of sand placement on beach and near-shore invertebrate populations and their recovery. Also, it is possible that Oregon Inlet ocean bar dredging sand could be used for beach nourishment in the Refuge; a cost-sharing arrangement between the NCDOT and the USACE is possible.

Wetlands

The Refuge area to the west of the forecast 2060 high erosion shoreline is almost entirely wetland. Thus, as shown in Table 2-8, approximately 70 to 80 acres (28.3 to 32.4 hectares) of wetlands would be filled by the NC 12 maintenance alternatives that involve relocating NC 12 west of the 2060 high erosion shoreline as a road. The alternatives including only nourishment and bridges would fill 1.8 to 8.5 acres (0.7 to 3.4 hectares) of wetland, substantially less than the road alternatives. The All Bridge Alternative, however, also would shade 25.8 acres (10.4 hectares) of wetland and its associated vegetation. By comparison, the Pamlico Sound Bridge Corridor Alternative would fill 1.2 to 1.8 acres (0.5 to 0.7 hectares) of wetland and bridge an additional 1.2 acres (0.5 hectares).

Section 404(b)(1) Guidelines of the Clean Water Act (CWA) (40 *Code of Federal Regulations* [CFR] 230), mitigation policy mandates articulated in the USACE/US Environmental Protection Agency (USEPA) MOA, and Executive Order 11990 (Title 42, *Federal Register* [FR] 26961 [1977]) all stress avoidance and minimization as primary considerations for protection of wetlands. Practicable alternatives must be evaluated fully before filling wetlands and associated compensatory mitigation for the wetland loss can be discussed. USFWS mitigation policy directives (46 FR 7644-7663 [1981]) also emphasize avoidance and minimization. Thus, the practicality of the bridging alternatives is an important consideration in making a decision to implement the alternatives that involve relocating NC 12 as a road rather than on a bridge.

Legal and Permit Requirements

In addition to Section 404 of the Clean Water Act (as noted in the previous section), the requirements of several other environmental protection laws apply to the assessment and selection of alternatives. Permits or certifications would need to be obtained from the USFWS, NCDENR's Division of Coastal Management, NCDENR's Division of Water Quality, and the NPS. Also, with any of these alternatives, since they all would involve a new utilization of Refuge land, the USFWS must find them compatible with the April 1938 Executive Order 7864, which reserved the Refuge to advance the purposes of the Migratory Bird Conservation Act and the National Wildlife Refuge System Improvement Act of 1997 in order to issue its permits. In addition, a US Coast Guard bridge permit would be required for either the Oregon Inlet bridge with the Parallel Bridge Corridor alternatives, or the Pamlico Sound bridge.

Section 4(f) of the Department of Transportation Act of 1966, as amended (49 USC 303), states that the US Department of Transportation may not approve the use of land from a significant

publicly owned park, recreation area, or wildlife and waterfowl refuge, or any significant historic site, unless a determination is made that the project will have a *de minimis* impact or unless a determination is made that:

- There is no feasible and prudent alternative to the use of land from the property; and
- The action includes all possible planning to minimize harm to the property resulting from such use.

Significant publicly owned park, recreation area, wildlife and waterfowl refuge, or any significant historic sites are known as Section 4(f) properties.

The Cape Hatteras National Seashore is a publicly owned park and recreation area. Both the Parallel Bridge Corridor discussed in this section and the Pamlico Sound Bridge Corridor would use land from the Seashore.

The Pea Island National Wildlife Refuge meets all four Section 4(f) criteria; it is a publicly owned park, a recreation area, a wildlife and/or waterfowl refuge, and a significant historic site. As such, since all of the Parallel Bridge Corridor alternatives examined in 2005 would involve a new utilization of Refuge land, the selection of any of them for implementation will require that the above determination be made.

Risk

The concept of risk includes any other factors that in the long-term could affect the viability and the cost of the Parallel Bridge Corridor alternatives under consideration. Two primary risks were identified: the potential for a storm-caused breach in the Refuge and accelerated erosion of nourished beaches.

Five potential breach locations are within the Refuge, so there is risk that a relocated road could be broken by a breach. Based on the opinions of the expert panel described in Section 3.6.3.4, the southern end of the Refuge is the most likely location through 2060 for a breach to occur. A breach in the Refuge would separate almost all of Hatteras Island and its associated communities, tourism businesses, and the Seashore from Bodie Island and the mainland. If a breach opens in an area where NC 12 is a surface road, the federal government or the state would then incur the additional cost of closing the breach. In addition, there would be the associated economic loss, challenges for maintaining community services, and disruptions to daily living until the breach is closed. Until the breach could be closed, a temporary ferry service using the emergency ferry docks in Rodanthe and Stumpy Point would be able to make 18 trips a day, transporting between 1,100 and 1,300 vehicles per day (vpd). The crossing time would be 1 hour and 40 minutes. However, the average annual daily traffic across Bonner Bridge in 2002 was 5,400 vpd, and it is forecast to increase to 9,600 vpd by 2025. Average summer weekend traffic across the Bonner Bridge was 10,900 vpd in 2002, and it is expected to rise to 19,200 vpd by 2025. The risk of a breach forming would be reduced with beach nourishment. Potential breach areas, particularly at the southern end of the Refuge, could be bridged as a part of the Parallel Bridge Corridor alternative.

A risk that should be considered with respect to beach nourishment is that faster erosion than forecast is possible, which would result in more nourishment and therefore raise both the associated cost and sand required. The risk of changes in sand requirements, and thus nourishment's cost being more or less than that presented in Table 2-8, was examined. It was concluded that potential differences in the rate of erosion could decrease the $644.0 million cost of the Nourishment Alternatives by $111.8 million, or increase it by as much as $137.7 million.

Other Environmental Impacts

The following additional environmental impact factors were found to be important to deciding which of the Parallel Bridge Corridor alternatives, including NC 12 maintenance, to evaluate in detail in the FEIS.

1. Threatened and endangered species could occur in the project area and will need to be considered in terms of the timing of construction and placement and dredging of sand.

2. Road relocation outside the existing easement in the ponds area would affect the NRHP-eligible Refuge. The Refuge was found to be eligible for the NRHP under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history (see Section 3.4.1.1). A letter dated September 17, 2003 from the North Carolina SHPO that affirms this finding is contained in Appendix A.

3. Based on the 1999 final design of the new Oregon Inlet bridge, the catwalks on Bonner Bridge were assumed to not be replaced. The deck of the new bridge, as depicted in the 1999 final design, would be approximately 40 feet (12.2 meters) above the water at the shoreline and approximately 65 feet (19.8 meters) above the water by the end of the first span (approximately 400 feet [121.9 meters] offshore). However, Dare County would like to see the catwalks replaced on the new bridge, or a piece of the existing Bonner Bridge retained as a fishing pier.

4. NC 12 relocation would affect the Refuge's wildlife trails, boat ramp parking, and access to the Refuge Visitor Center and Headquarters. Relocation of NC 12 west of the ponds would have the greatest effect on trails, crisscrossing the existing North Pond dike trail and forcing bird watchers and walkers to walk along the road. Also, a location west of the ponds would reduce the accessibility of the beach in this area.

5. An interim road relocation at Rodanthe, in order to delay construction of a Rodanthe area bridge, would displace 8 to 13 homes.

2.6.4 Parallel Bridge Corridor Alternatives Defined for Detailed Evaluation

Based on the study findings presented above, coordination with resource and regulatory agency representatives, and the October 13, 2004 Merger Agreement, three Parallel Bridge Corridor with NC 12 Maintenance alternatives were defined in 2005 for detailed evaluation in this FEIS. They are:

- Nourishment. Maintenance of NC 12 in the existing right-of-way through beach nourishment with dunes at several locations;

- Road North/Bridge South (identified in Section 2.6.3.1 as Relocate Road North (West of 2060 Shoreline)/Bridge South). NC 12 relocation to the west as a road in the northern half of the Refuge and on a bridge in the Rodanthe area; and

- All Bridge. NC 12 relocation to the west on a bridge both in the northern half of the Refuge and in the Rodanthe area.

The alternatives selection meetings in late-March and early-April 2005 yielded the conclusion that most of the alternatives had both merit and concerns from different perspectives. For example, nourishment would allow NC 12 to remain in its existing right-of-way, but would be expensive and could adversely affect beach organisms in both the short- and long-term. Relocating NC 12 as a road is the least costly option, but would require filling the most wetlands. Relocating NC 12 on a bridge would minimize wetland loss but would be expensive. Therefore, it was decided that the broad range of NC 12 maintenance options reflected by the three selected alternatives should be evaluated and contrasted in detail in this FEIS.

Three of the preliminary alternatives were dropped from further consideration. Relocating NC 12 west of the freshwater ponds in the Refuge was dropped because meeting participants agreed that it would have the greatest impact on Refuge operations and use. A short-term relocation of NC 12 in the northern Rodanthe area, followed by a later second relocation of NC 12 on a bridge, was also dropped because it increased wetland impacts, displaced homes, and increased the total cost of maintaining NC 12 through 2060. These concerns were judged to offset the desirability of delaying the cost of the bridge in the Rodanthe area by initially building the short-term road relocation, given that a new road costs less than a new bridge. Nourishment North/Bridge South also was dropped because its components would be assessed within the context of the Nourishment and Road North/Bridge South alternatives.

The NEPA/Section 404 Merger Team was briefed on this decision at a meeting on May 24, 2005.

2.7 2006 Parallel Bridge Corridor with NC 12 Maintenance Alternatives Studies

An additional set of Parallel Bridge Corridor with NC 12 Maintenance studies was conducted in 2006. These studies focused on the development of what are called the Phased Approach alternatives (including the Preferred Alternative). The Phased Approach alternatives (including the Preferred Alternative) were developed in response to a proposal made during the comment period following the release of the SDEIS. As suggested, the Phased Approach alternatives (including the Preferred Alternative) assume an Oregon Inlet bridge (the design of which is slightly different from the other Parallel Bridge Corridor alternatives) and elevating parts of NC 12 through the Pea Island National Wildlife Refuge (the Refuge) to new bridges within the existing NC 12 easement. The bridges built for NC 12 would be constructed in several phases, based on the forecast high erosion shoreline, as well as the location and likelihood of future breaches on Hatteras Island. The goal of these alternatives was to avoid the use of Refuge lands for which Section 4(f) of the Department of Transportation Act applies (see the introduction to Chapter 5 for a description of the requirements of Section 4(f)), while at the same time spreading the cost of the project over a longer time period given limits of annual transportation improvement funding.

The initial design assumptions for the Phased Approach alternatives (including the Preferred Alternative) were developed by NCDOT and FHWA in March 2006, based on the parameters defined in the SDEIS comment discussed in the previous paragraph. These assumptions were used to develop a rough cost estimate for comparison with the detailed study alternatives assessed in the SDEIS. When considering the total expenditure through the year 2060, these cost estimates indicated that the Phased Approach alternatives (including the Preferred Alternative) would be higher in cost than the other detailed study alternatives. The primary advantage, unlike the other alternatives, except the Parallel Bridge Corridor with Nourishment Alternative, was that the

construction cost could be spread over many years instead of concentrated between the start of construction and 2013. Construction would be phased to correspond to forecast shoreline erosion trends, maintaining a buffer distance between existing NC 12's edge of pavement and the active shoreline. The cost estimates were presented for discussion at a June 15, 2006 meeting of the project's NEPA/Section 404 Merger Team (see Section 8.8.1.1).

In order to examine the technical feasibility of the Phased Approach alternatives (including the Preferred Alternative), the NCDOT held a Constructability Workshop from August 29 to 31, 2006. The workshop was modeled after the Accelerated Construction Technology Transfer (ACTT) process championed and implemented by FHWA for notable projects nationwide. The workshop began with a general session that introduced the project history, the dynamics of the site, and the concept of a Phased Approach Alternative. Days two and three of the workshop were devoted to a brief site visit followed by numerous discussion sessions.

Attendees at the workshop included engineers and other technical staff from FHWA and NCDOT. In order to gain a broader perspective on feasibility, national experts in the fields of shoreline migration, geotechnical engineering, structural engineering, hydraulic engineering, coastal engineering, and bridge construction also participated. Other disciplines represented included roadway engineering, traffic control, intelligent transportation systems, pavement design, planning, maintenance, materials, and utility engineering. Contractors, consultants, and academics were represented.

The workshop concluded that a Phased Approach Alternative was technically feasible, although technically challenging (NCDOT, September 2006). A description of a design and construction approach at the southern terminus of a new parallel bridge over the Oregon Inlet, as well as the bridges along NC 12 in the Refuge were developed. Design and constructability issues discussed at the workshop were predicated on the assumption that construction must occur fully within the NCDOT's existing 100-foot (30.5-meter) easement within the Refuge. The recommendations of this workshop served as the basis for the design assumptions used in assessing the Phased Approach alternatives (including the Preferred Alternative) in this FEIS. The workshop results were presented for discussion at a September 21, 2006 meeting of the project's NEPA/Section 404 Merger Team (see Section 8.8.1.2).

Following the workshop and the September 21, 2006 Merger Team meeting, the NCDOT decided to evaluate the alternatives in this FEIS. Two variations of the Phased Approach alternatives (including the Preferred Alternative) were defined for detailed evaluation:

- Phased Approach/Rodanthe Bridge Alternative (Preferred); and
- Phased Approach/Rodanthe Nourishment Alternative.

The design assumptions associated with the Phased Approach alternatives (including the Preferred Alternative) are discussed in Section 2.10. The project's NEPA/Section 404 Merger Team was given an opportunity to discuss the design assumptions at a December 14, 2006 meeting (see Section 8.8.1.3).

2.8 2006 Long Bridge Operations and Safety Study

A Long Bridge Operations and Safety Study (Parsons Brinckerhoff Quade & Douglas, Inc., June 2006) was conducted in 2006 to address questions about the safe operation of long bridges that

were raised at the November 2005 public hearing and during SDEIS review. These concerns dealt specifically with the proposed Pamlico Sound Bridge Corridor Alternatives that include a 17.5-mile bridge crossing of the Sound. Its findings, however, also apply to the Parallel Bridge Corridor's All Bridge and Phased Approach alternatives (including the Preferred Alternative). The study focused on several factors: operational; weather; crash and vehicular safety; and other issues related specifically to long bridges.

The study involved the use of the results of internet research, an examination of crash statistics, and interviews with officials responsible for other existing long bridges. Four long bridges were considered: the Chesapeake Bay Bridge-Tunnel (CBBT) in Virginia; the Lake Pontchartrain Causeway in Louisiana; the Confederation Bridge in Prince Edward Island, Canada; and the Seven Mile Bridge in the Florida Keys.

2.8.1 Operational Concerns

Interviews with bridge officials determined that safety and response time to vehicular incidents were paramount operational concerns. The two primary issues were:

- Vehicles and passengers on the bridge are isolated from emergency assistance. Emergency response times can be long because of the bridge distance involved, and it is crucial to reduce total response time by reducing incident detection times.

- Stalled vehicles on long bridges introduce additional safety issues, both to other cars that must avoid the stopped vehicle and to the passengers in the stopped car that are exposed to potential hazards caused by high speed traffic operations.

All of the interviewees said that an important consideration in operating a long bridge is rapid response to emergencies and incidents with proper equipment and personnel. Specific considerations for emergency services and incident response included incident detection (which consists of multiple methods, including closed circuit television (CCTV) cameras to monitor all locations on the bridge); incident response, removal of stalled vehicles, ability of emergency vehicles to turn around on a bridge; variable message signs; other intelligent transportation system (ITS) technologies; and a dedicated staff for incident detection and response.

2.8.2 Weather

Another safety factor to consider is adverse weather, particularly wind, fog, and winter weather. The long bridges examined have various restrictions during occurrences of high wind. The most comprehensive wind standards are in place at the CBBT. Prior to April 1999, the CBBT was a two-lane structure, and the original wind policy on the two-lane and shoulder-less facility was developed to reduce the risk of vehicles being blown partially or completely across the center-line and causing a head-on collision. The separate southbound structure opened in 1999, and the wind policy was updated at that time for the four-lane structure. Both the two-lane and the four-lane wind policies call for the restriction of certain vehicles based on wind speed; however, the current four-lane policy is less restrictive (i.e., the minimum wind speeds at which each type of vehicle restriction occurs were increased) because it reflects the fact that there are now two bridges with traffic flowing in one direction on each bridge.

Wind conditions on a potential Bonner Bridge replacement were compared to wind condition restrictions with the original two-lane wind policy on the CBBT. The CBBT's two-lane wind

restriction policy was used in this comparison because the Bonner Bridge replacement project alternatives are all two-lane structures, although the Bonner Bridge replacement would have shoulders whereas the two-lane CBBT had no shoulders. The two-lane wind restriction policy on the CBBT was as follows:

- 17.3 to 28.7 mph (27.8 to 46.2 kph) – no car-top carriers or loaded roof racks;
- 28.8 to 40.2 mph (46.3 to 64.7 kph) – no recreational trailers or lightweight recreational vehicles;
- 40.3 to 45.9 mph (64.8 to 73.9 kph) – no recreational vehicles of any type or canvas-topped semi-trailers;
- 46.0 to 51.7 mph (74.0 to 83.2 kph) – no empty semi-trailers or empty six-wheel trucks;
- 51.8 to 57.4 mph (83.3 to 92.4 kph) – no motorcycles;
- 57.5 to 68.9 mph (92.5 to 110.9 kph) – no passenger cars, light trucks, or busses (only heavily loaded semis allowed); and
- 69 mph (111.0 kph) or greater – closed to all traffic.

For comparison, in Dare County the goal is to complete hurricane evacuations before the arrival of gale force winds, which are defined as sustained winds at 39 to 54 mph (62.7 to 86.9 kph). It was determined that the same levels of wind speed were reached on Hatteras Island as on the CBBT; however, the length of time each year experiencing these wind speeds was far greater on the CBBT than on Hatteras Island. The percentage of the total hours exceeding 17.3 mph (27.8 kph) for the CBBT (26.39 percent) is more than three times the percentage of Hatteras Island (7.83 percent).

The daily occurrence of moderately high winds in the Hatteras Island area, as well as the experience and wind policies of existing long bridges, indicate a likely need for a wind monitoring system, a wind policy, procedures and facilities needed to enforce that policy, and safety features to reduce the potential for crashes on a long Bonner Bridge replacement. The details would be developed during final design, taking into consideration the unique setting and characteristics of the replacement bridge.

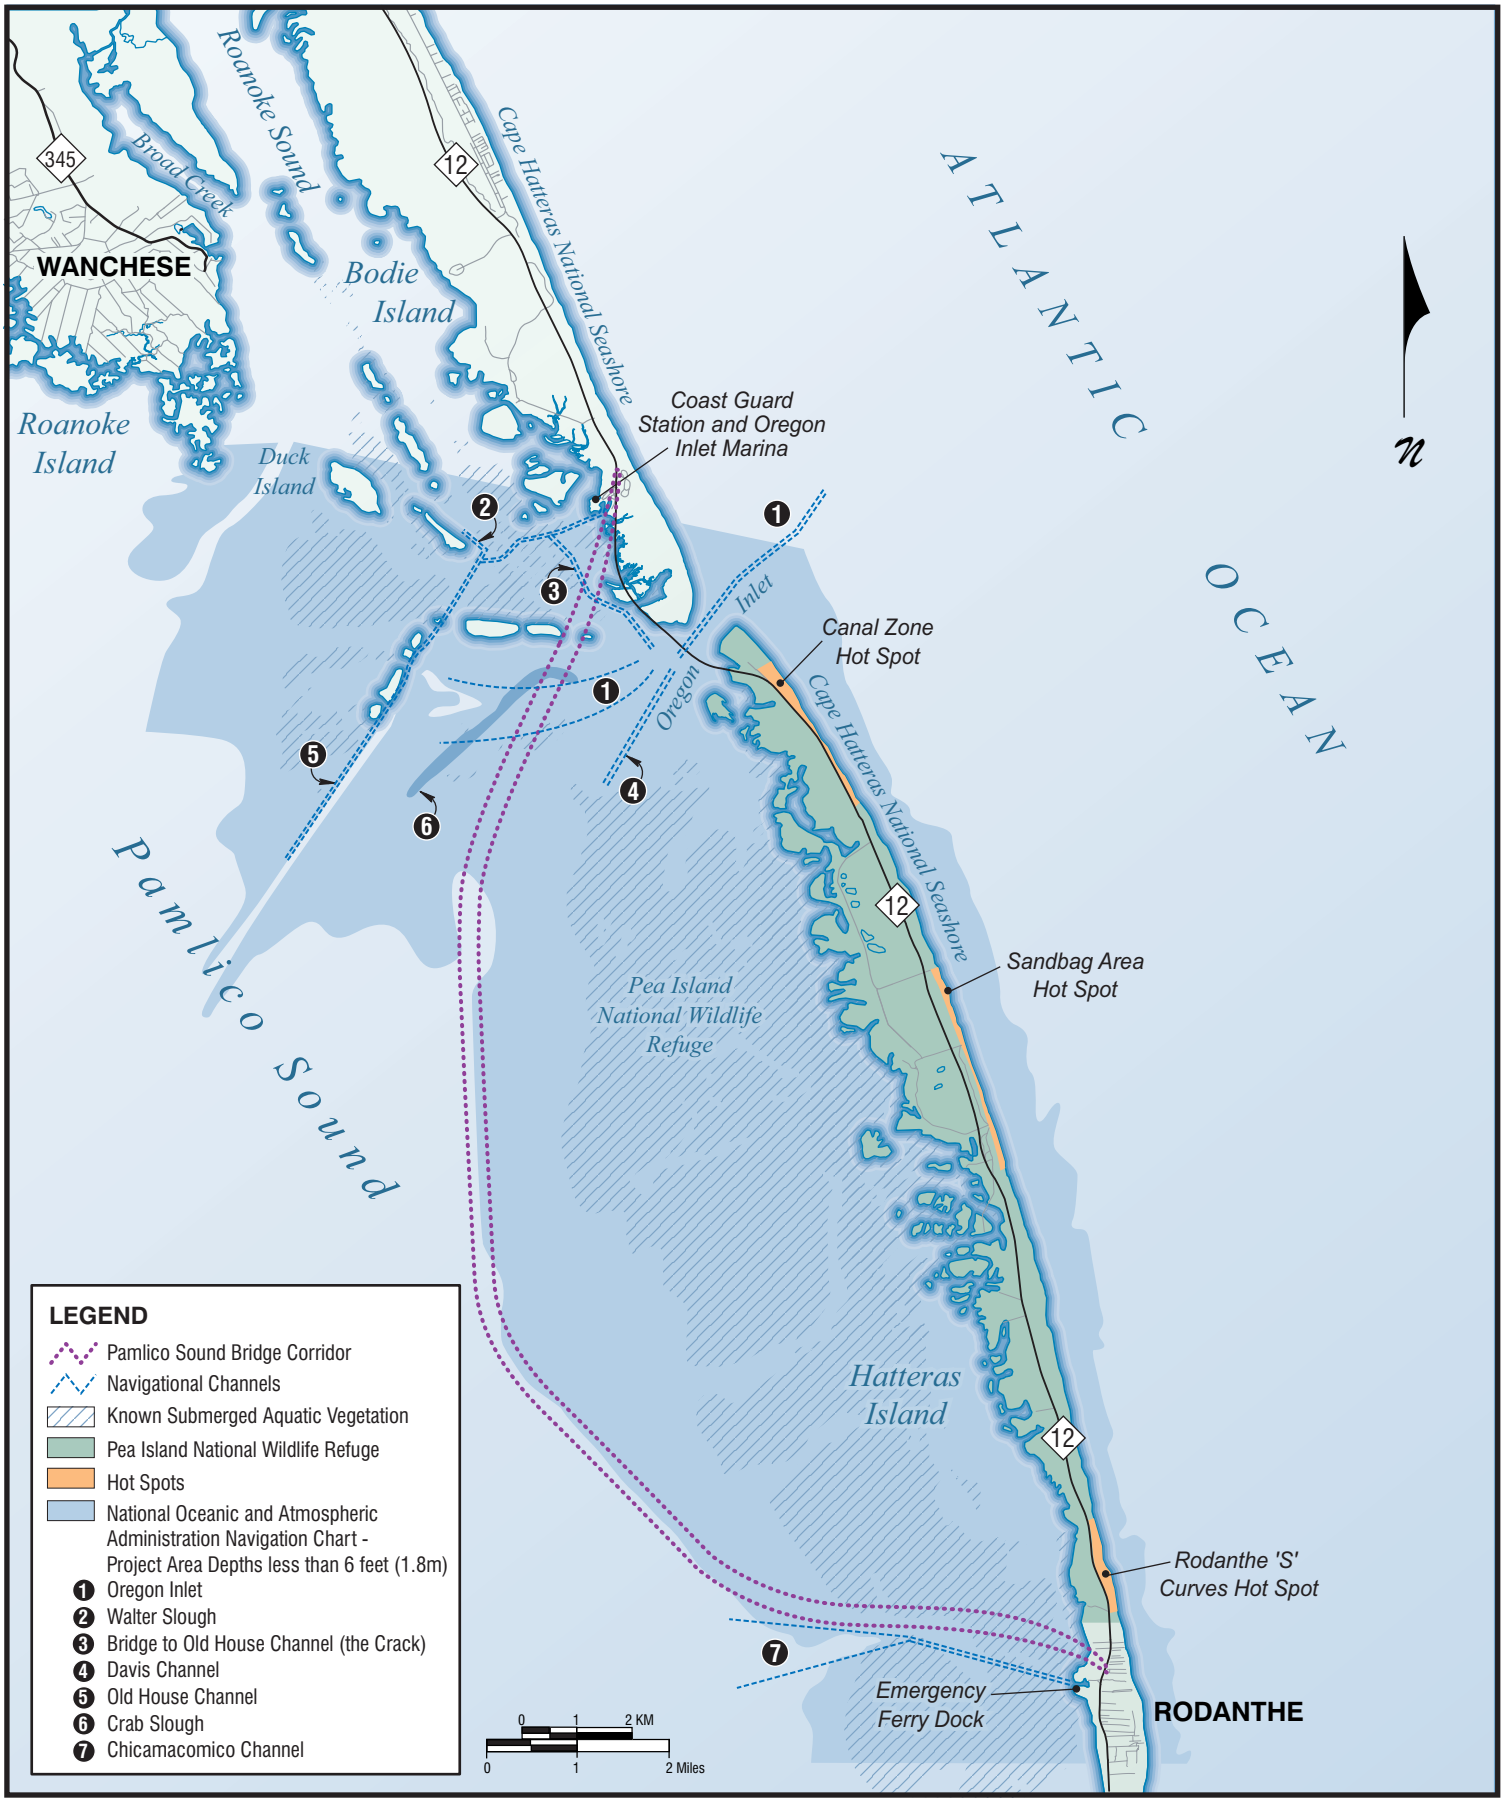
Another potential issue in the operation of a long bridge is fog. Fog conditions, and existing policies to address fog conditions on the other long bridges, were reviewed. It was determined that, given the potential Pamlico Sound bridge's design criteria and the visibility experience at the Hatteras Island weather station, low visibility because of fog would seldom be a problem on a replacement bridge.

Winter conditions present a third consideration in terms of long bridge operation. Current NCDOT experience and maintenance practices in the Outer Banks area indicate that winter weather can be an issue but does not occur frequently. Currently, sand and salt applications are utilized for snow and ice in the winter.

2.8.3 Crashes and Safety

Using NCDOT crash data, crash rates were reviewed for NC 12, including Bonner Bridge and other longer bridges in eastern North Carolina. The crash rate on NC 12, except in the Rodanthe area, was very low (below 52 crashes per 100 million vehicle miles) compared with the two-lane statewide average (171.66 to 184.65 crashes per 100 million vehicle miles). Crashes on Bonner Bridge are of a limited number of types (i.e., head on, rear end, sideswipe, and fixed object) because there are no access points to introduce turning traffic. North and south of Bonner Bridge and in Rodanthe, the majority of crashes involved turning vehicle or animals.

Crash rates on long bridges in North Carolina, as well as on the CBBT were compared to both the average and critical crash rates on two and four lane roads in North Carolina. The crash rates on these bridges for a three year period (2002 to 2005) were much lower (30 to 50 crashes per 100 million vehicle miles) than the average and critical crash rates observed statewide on two and four lane roads. Average crash rates for two and four-lane roads in North Carolina are 171.66-184.65 crashes per 100 million vehicle miles and 137.56 crashes per 100 million vehicle miles, respectively. Critical crash rates for two and four-lane roads in North Carolina are 211.43 to 315.73 crashes per 100 million vehicle miles and 161.74 to 173.21 crashes per 100 million vehicle miles, respectively. The low crash rate on long bridges is because of the lack of turning traffic and access points on the bridges.



2.8.4 Application to the Detailed Study Alternatives

Based on the findings of the Long Bridge Operations and Safety Study, the detailed study alternatives in the Pamlico Sound Bridge and Parallel Bridge corridors are assumed to include turnouts every 3 miles (4.8 kilometers). These are included in the bridge costs so that a disabled vehicle can be moved out of the way of traffic. During final design, the NCDOT also would consider implementation of the following ITS devices to provide motorists with advance notification as to travel conditions in the NC 12 corridor and on the replacement bridge: Highway Advisory Radio (HAR), Roadway Weather Information Systems (RWIS), Variable Message Signs (VMS), and CCTV cameras, as well as fiber optic cabling to link the technologies and incident management patrols.

2.9 Description of Pamlico Sound Bridge Corridor Alternative (Selected for Detailed Study)

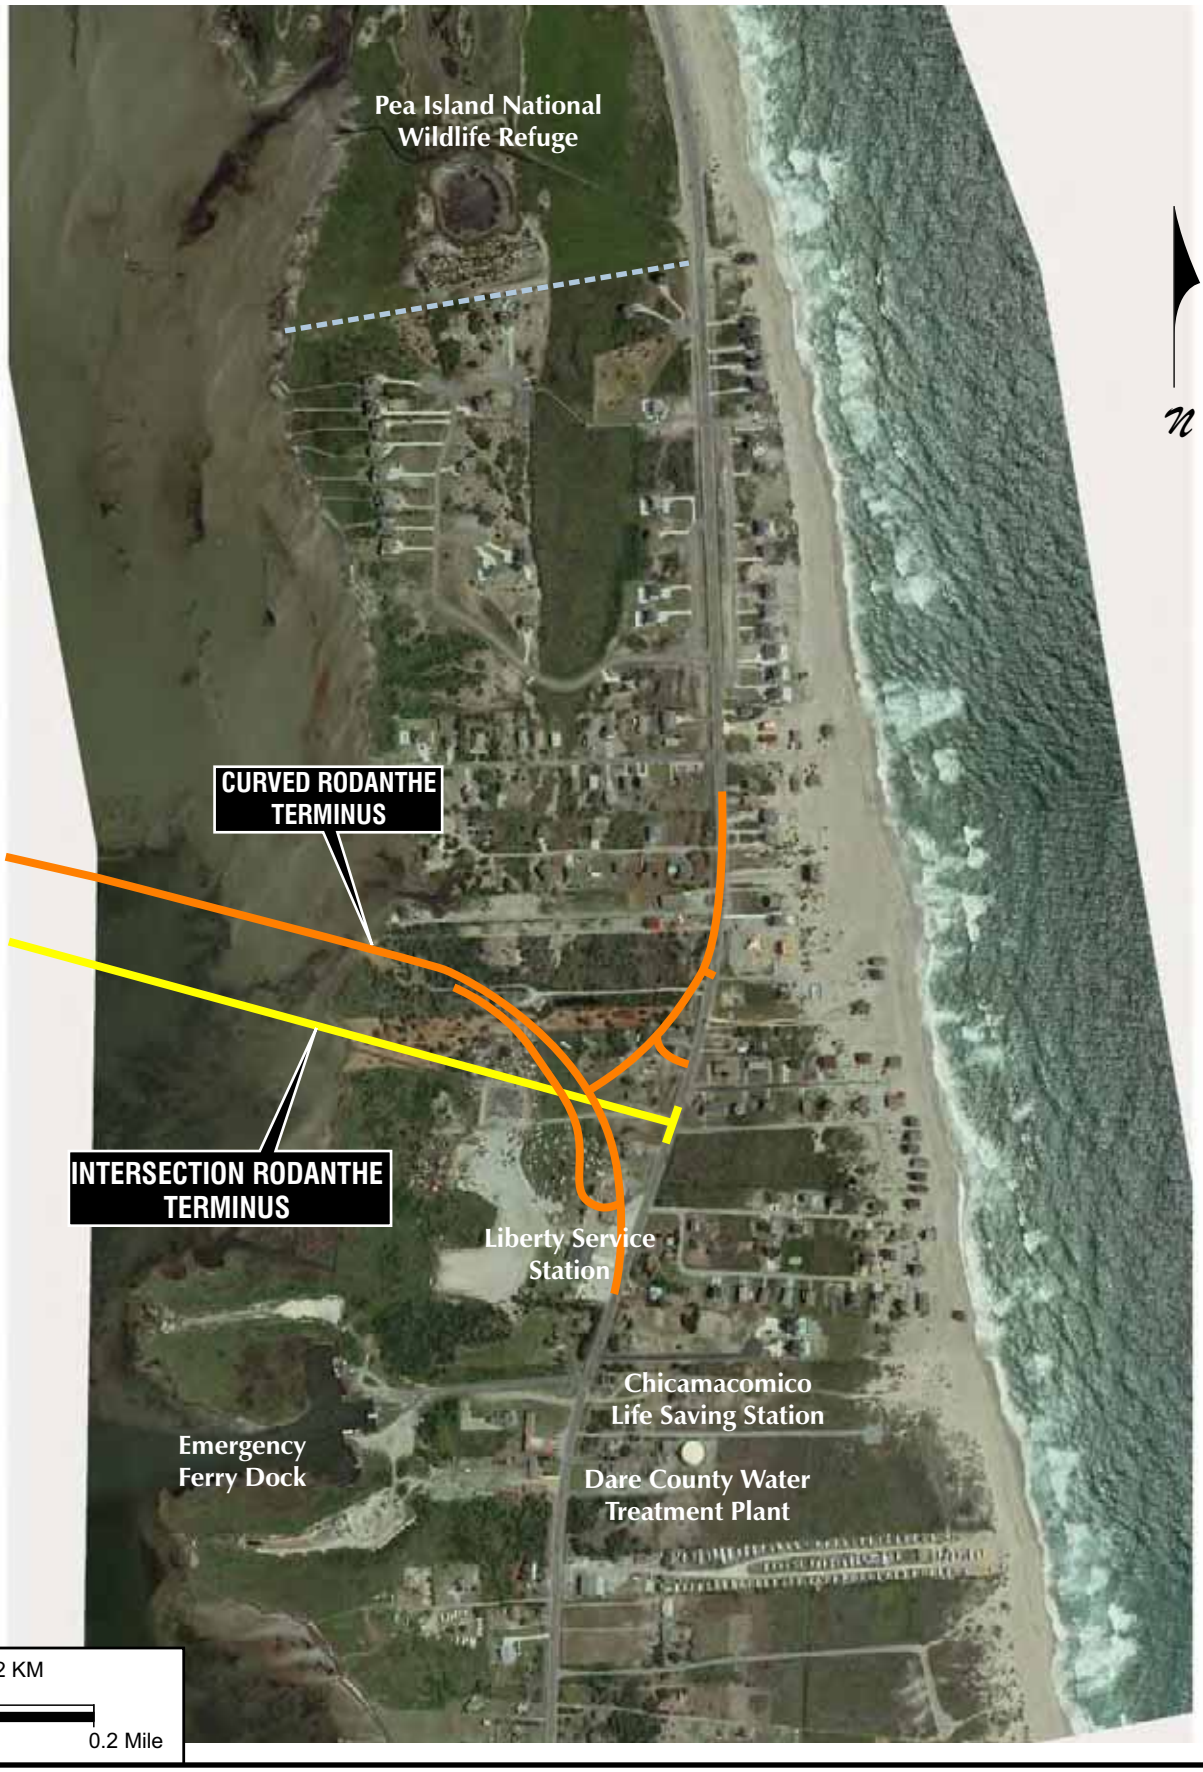
The Pamlico Sound Bridge Corridor Alternative includes a replacement bridge that begins approximately 1,200 feet (366 meters) north of the emergency ferry dock in Rodanthe and extends west into Pamlico Sound and turns to the north to parallel Hatteras Island for approximately 9 miles (14.4 kilometers), approximately 5 miles (8 kilometers) west of Hatteras Island. The bridge would then turn to the northeast and terminate at the northern terminus of Bonner Bridge on Bodie Island. The location of this corridor is illustrated in Figure 2-11.

The design features and approaches to construction described in this FEIS were developed based on the best available data at the time. These descriptions were prepared to provide the readers of this FEIS with an understanding of the expected characteristics of each alternative and for use in estimating project cost, level-of-service, and environmental impact. It is assumed that the specific design features (including, bridge span types and arrangements) and approaches to construction described here could change during final project design or by the design-build

PAMLICO SOUND BRIDGE CORRIDOR

Figure 2-11

contractor, preparation of permits, and the development of final mitigation measures, should this alternative be selected as the Preferred Alternative. It is not anticipated, however, that such refinements would result in substantial changes to project costs or impacts, or changes to the commitments that are contained in the Project Commitments section of the FEIS.



It is assumed that if it were decided that maintaining paved road access the full length of the Refuge is essential, a Parallel Bridge Corridor with NC 12 Maintenance alternative likely would be selected for implementation. The implementation of a combination of the Pamlico Sound Bridge Corridor and long-term maintenance of NC 12 as a paved road the full length of the Refuge would achieve no travel or environmental benefits over the implementation of a Parallel Bridge Corridor with NC 12 Maintenance alternative, but would have a substantially greater long-term cost.

If the Pamlico Sound Bridge Corridor had been selected as the Preferred Alternative, the Refuge and the NPS had indicated that they intended to maintain some type of access for visitors to the Refuge. However, based on the USFWS's concerns about the affect of the existing paved NC 12 on the Refuge, the method of access likely would have been something different than a paved road. NCDOT indicated that it would seek an opportunity to participate in the decision-making process to determine what that access will entail. In coordination meetings with USFWS and NPS, representatives gave no indication that they expect the State of North Carolina to contribute to the cost of their alternate access program; it would, however, have been a public cost (funded with public monies). Options for alternate access could include permitting visitors to drive on the beach or other designated sand route, a jitney service along a designated sand route, moving some visitor facilities (such as the Visitor Center) closer to Rodanthe, or some combination of options. If a storm-caused breach were to occur at the southern end of the Refuge, it would either need to be closed or ferry service implemented if the USFWS wished to continue to get visitors and their vehicles to and from the Refuge.

Two possible Rodanthe termini design options are evaluated in this FEIS, as illustrated in Figure 2-12. With the Curved Rodanthe Terminus, the proposed bridge would end in a curve that connects the bridge directly to NC 12. With the Intersection Rodanthe Terminus, the proposed bridge would end with a signalized intersection at NC 12. The merits of these two termini options are discussed in this section from a traffic operations perspective. Their differences from an environmental impact perspective are described in Chapter 4. The subsections that follow in this section describe the:

- Pamlico Sound Bridge Corridor location;
- Bridge characteristics;
- Approach roadway characteristics;
- Rodanthe terminus options; and
- Construction procedures.

Demolition and removal of Bonner Bridge and the disposition of parts of NC 12 replaced by the alternatives are discussed in Section 2.11 Costs and funding for the alternatives associated with both bridge replacement corridors evaluated in detail in this FEIS are discussed in Section 2.12. Environmental Protection during construction of the proposed project is discussed in Section 2.13. Permits and approvals are discussed in Section 2.14.

PAMLICO SOUND BRIDGE CORRIDOR - RODANTHE CURVED AND INTERSECTION TERMINUS OPTIONS

Figure 2-12

2.9.1 Pamlico Sound Bridge Corridor Location

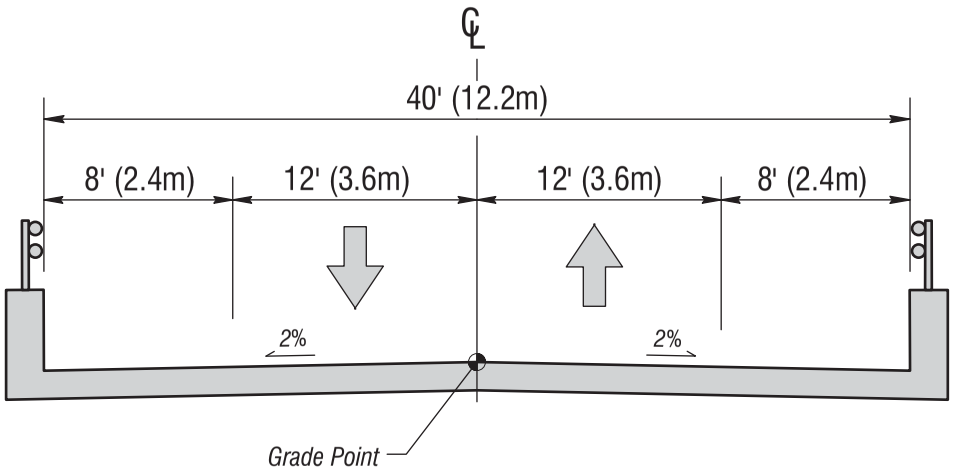
The proposed bridge would be approximately 17.5 miles (28.2 kilometers) in length, and, if constructed, would be the third longest bridge behind the Lake Pontchartrain Causeway in Louisiana, which is the longest bridge in the world at 23.9 miles (38.5 kilometers) in length. The only other bridge in the world that would be longer than the proposed 17.5-mile (28.2-kilometer) Pamlico Sound Bridge Corridor bridge is the 22.3-mile (35.9 kilometer) Hangzhou Bay Bridge in China, which was completed in 2008. There are only two other bridges in the world that are over 11 miles (17.7 kilometers) in length: the Saudi-Bahrain Causeway over a portion of the Persian Gulf between the countries of Saudi Arabia and Bahrain (16.2 miles [26.1 kilometers]), and the Chesapeake Bay Bridge-Tunnel on US 13 over the mouth of the Chesapeake Bay in Virginia (15.0 miles [24.1 kilometers]).

The location of the Pamlico Sound Bridge Corridor is illustrated in Figure 2-11. The proposed bridge would:

- Begin in Rodanthe in an area that is less developed, beginning either at a signalized intersection (Intersection Rodanthe Terminus) or a sweeping curve that connects the bridge directly with NC 12 (Curved Rodanthe Terminus).

- Continue west from Rodanthe and north of the channel used by ferries when the emergency ferry dock in Rodanthe is operated.

- Turn north and continue north parallel and up to approximately 5 miles (8 kilometers) west of Hatteras Island. This location is west of known SAV beds and in an area that generally is deep enough for a construction barge to operate without the need for dredging. This location would help minimize impacts to the sound bottom and increase the efficiency of the construction process.



- Cross the existing navigation channel for vessels using Oregon Inlet approximately 6,500 feet (1,981 meters) west of Bonner Bridge.

- Cross Bridge to Old House Channel, commonly known as "the crack," at a point approximately 4,900 feet (1,494 meters) south of the proposed bridge's northern endpoint, and continue north on the east side of that channel. The channel is used informally by the recreational fishing fleet. This is the point where, as of year 2003, Bonner Bridge enters open water, and "the crack" turns briefly east and then south to closely parallel Bonner Bridge.

- Terminate at the existing Bonner Bridge terminus on Bodie Island, following a route between Bonner Bridge and the parking lot for the Oregon Inlet Marina and Fishing Center (see Figure 2-12).

2.9.2 Bridge Characteristics

The bridge's typical section would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders. The bridge's typical section is illustrated in Figure 2-13. The proposed bridge's navigation spans in the Oregon Inlet area would provide a minimum navigation opening of 200 feet (61 meters) horizontally and 75 feet (23 meters) vertically. The navigation zone (area with spans of the navigation span height and width) would be 1,600 to 2,000 feet (488 to 610 meters) long. The NCDOT anticipates that the typical bridge span outside the navigation zone

BRIDGE TYPICAL SECTION

Figure
2-13

would be 140 to 150 feet (42.7 to 45.7 meters). Outside the navigation zone, the vertical clearance of the bridge currently is expected to be approximately 10 feet (3.1 meters) above mean high water. These are considered reasonable span and clearance assumptions for the purpose of analysis in this FEIS, but could change in project design.

One navigation zone would be built to serve boats passing through Oregon Inlet. The location of the zone would be determined in coordination with the USACE and the US Coast Guard. The USACE currently maintains the Oregon Inlet/Old House navigation channel. As discussed in Section 3.6.3, movement of Oregon Inlet over the life of the proposed bridge could shift the natural channel gorge to the Davis Channel area. The NCDOT's goal would be to place the navigation zone of the proposed bridge in a location that reduces channel maintenance over the full life of the proposed bridge. The navigation channel(s) would be marked (i.e., with buoys, lighting, etc.) for navigation in accordance with the requirements of the US Coast Guard, the USACE, and the NCDOT.

A design speed (maximum safe speed that can be maintained under favorable driving conditions) of 60 miles per hour (96.6 kilometers per hour) was assumed for the bridge, as well as a maximum 5 percent grade and a bicycle-safe bridge rail.

For the bridge superstructure (spans between piers), the use of precast concrete segmental box girders is anticipated (see Section 2.9.5). It is, however, possible outside the navigation zone that the winning Design-Build (D-B) Contractor could choose to use precast concrete girders ("I" shape) similar to that used on Bonner Bridge. A box girder is a concrete girder with a typical-section shaped like a box. Box girder spans would be manufactured in segments (segmental construction) and assembled at the construction site. Precast segments (or concrete girders ["I" shape]) are anticipated, however, because of the following factors: faster construction, the higher quality of the precast elements, longer life, lower maintenance requirements, the ability to maintain segment casting production through the winter, and the difficulties of providing ready-mix concrete in a remote setting where water flow, wind, and exposure to the environment are constant forces.

For the bridge substructure (foundation and support for the superstructure), precast piles are anticipated. These piles would be jetted (high-pressure water is used to move sand aside so the pile can drop into place) or, in some cases, driven (hit with a large hammer or vibrated to drive the piles into the ground). With jetted piles, it is common to use a pile driver to seat the pile (to bring it to its final stopping point).

In the navigation zone, a footing could be cast near the waterline on top of the piles. A column or columns would be placed on top of the footing, which would in turn support the bridge superstructure. Outside the navigation zone, piles would extend out of the water to a point just under the bridge superstructure. Pile caps would be cast on top of the piles to support the superstructure.

The NCDOT would incorporate Best Management Practices (BMPs) for storm water management into the bridge design.

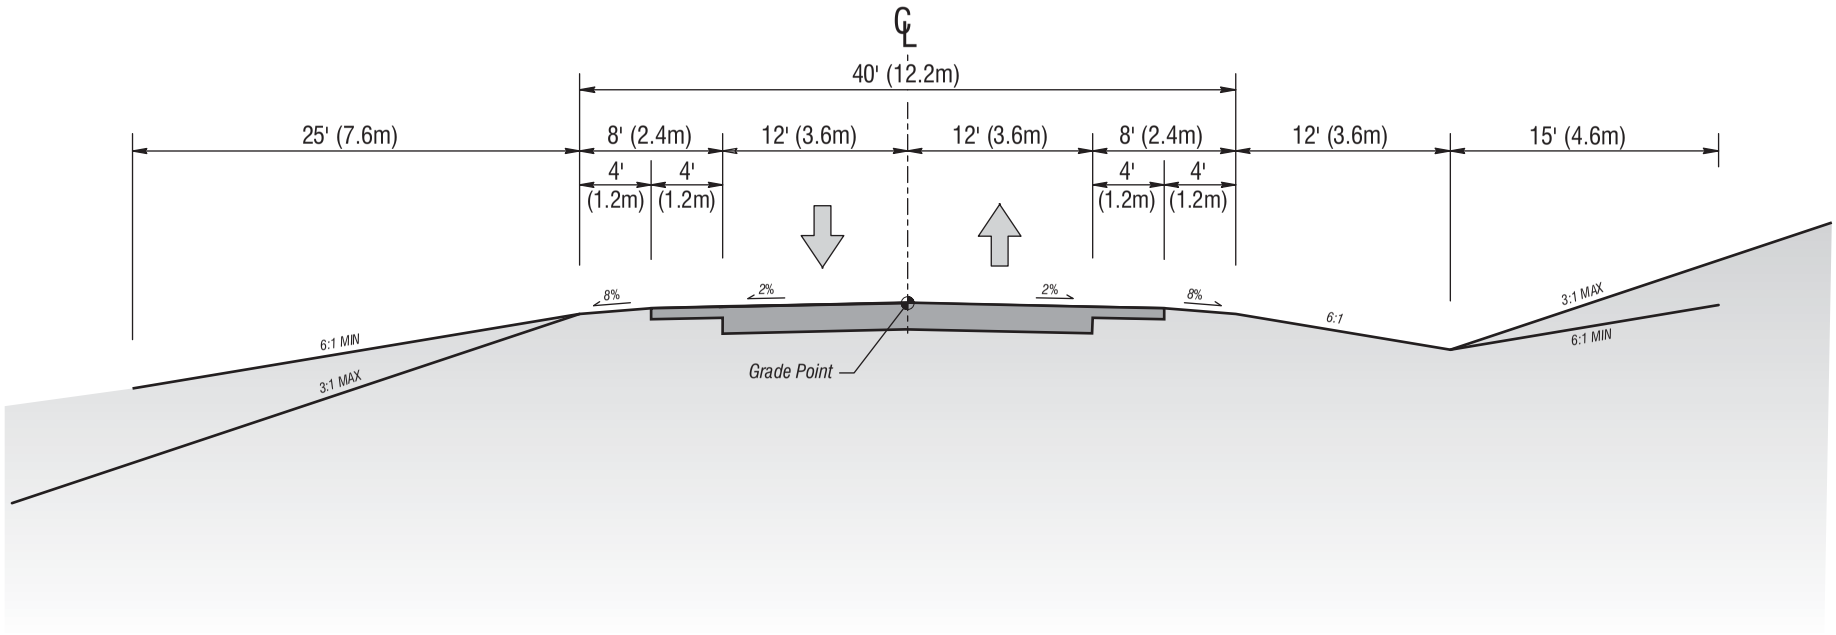
A preliminary examination of potential safety features for the proposed bridge in the Pamlico Sound Bridge Corridor was conducted in June 2006 (Parsons Brinckerhoff Quade & Douglas, Inc.) (see Section 2.8). It focused on several factors: operational considerations, weather considerations, crash and vehicular safety considerations, and other issues related specifically to long bridges. The cost estimates assume that turn-outs, where a disabled vehicle can be moved out of the way of

traffic, are built on the bridge. The maximum desirable distance between these turn-outs was assumed to be 3 miles (4.8 kilometers). ITS is the term for the use of technology to operate transportation facilities more efficiently, as well as to provide road condition information to the traveling public. During final design, NCDOT also would consider implementation of ITS devices to provide motorists with advance notification as to travel conditions in the NC 12 corridor and on the replacement bridge. Examples of ITS devices are: HAR, RWIS, VMS, and CCTV cameras, as well as fiber optic cabling to link the technologies and incident management patrols. Costs for such features are included in the cost estimates for this alternative in Section 2.12.

Helicopters used to evacuate seriously injured accident victims would be able to land on the 40-foot-wide (12.2-meter) proposed bridge. (Personal communication, January 6, 2004, Larry Mimms, Dare County EMS.) In addition, the 40-foot (12.2-meter) width of the proposed bridge would provide adequate space for other emergency vehicles to turn around and return to their station after responding to an emergency on the proposed bridge. (Personal communication, January 6, 2004, John Jones, Dare County EMS.)

Cable television and telephone lines could be accommodated on the proposed bridge. New transmission lines would be placed on, or adjacent to, the proposed bridge to replace those on Bonner Bridge. The Cape Hatteras Electric Cooperative would prefer to attach cables or aerial lines to the proposed bridge. If that option is not available to the Cooperative, an independent structure adjacent to the proposed bridge would be constructed. The aerial lines would be attached to the independent structure and maintained from the shoulder of the proposed bridge. Disruption of service as it is switched from the existing lines to the replacement lines would be minimal.

The 8-foot (2.4-meter) wide shoulders on the proposed bridge would be safer for use by bicycle and pedestrian traffic than Bonner Bridge's 2-foot (0.6-meter) wide shoulders. In addition, the planned bicycle-safe bridge rail on the proposed bridge would also provide increased safety for bicyclists.



2.9.3 Approach Roadway Characteristics

Approach roadway on fill at each end of the bridge structure would be:

- Approximately 1,550 feet (472 meters) long on Bodie Island;
- Approximately 968 feet (295 meters) on Hatteras Island with the Curved Rodanthe Terminus; and
- Approximately 680 feet (207 meters) on Hatteras Island with the Intersection Rodanthe Terminus.

Thus, total project length would be 18 miles (29 kilometers) long, including the bridge and the approach roadways.

The approach roadway typical section would have two 12-foot (3.6-meter) travel lanes with 8-foot (2.4-meter) shoulders (4-foot/1.2-meter paved). Eight feet (2.4 meters) of clearance from the edge of the travel lane to the face of the guard rail would be provided (see Figure 2-14). Fill is expected to be a maximum height of 12 feet (3.6 meters).

ROADWAY TYPICAL SECTION

Figure
2-14

On the Bodie Island approach roadway, a 60 mile per hour (96.6 kilometers per hour) design speed was assumed. On Hatteras Island approach roadway, a 50 mile per hour (80 kilometers per hour) design speed was assumed. Side slopes of 6:1 (minimum) to 3:1 (maximum) were assumed for fills on the approach roadways (1 foot [0.3 meters] of height for every 3 to 6 feet [0.9 to 1.8 meters] of width).

2.9.4 Rodanthe Terminus Options

Two terminus options are being considered where the Pamlico Sound Bridge Corridor ends in Rodanthe (see Figure 2-12):

- A curved terminus; and
- An intersection terminus.

The differences in community, cultural resource, natural resource, and other impacts of these two options are described in Chapter 4. Two options are being evaluated because they have differing advantages and disadvantages.

From a traffic operations perspective, the two Rodanthe termini options differ as follows:

- The Curved Rodanthe Terminus would connect the bridge directly to NC 12. Users of the bridge would not have to make a turn to enter onto or exit the bridge. With the Intersection Rodanthe Terminus, users of the bridge would turn at an intersection of NC 12 to enter or leave the bridge.
- With the Intersection Rodanthe Terminus, all southbound bridge traffic would have to at least slow down to turn at the signalized intersection before leaving the bridge and entering the Rodanthe section of NC 12 with its slower speeds and numerous cross streets and driveways intersecting NC 12. With the Curved Rodanthe Terminus, southbound bridge traffic would not be forced to slow before entering Rodanthe.
- With the Curved Rodanthe Terminus, a traffic signal could be installed in the future, if necessary, to aid traffic movement to and from the existing segment of NC 12 north of the Rodanthe bridge terminus. The level of service at the possible future signalized intersection with local roads would be:
  - A on a 2025 peak season weekday;
  - B on a 2025 peak season weekend; and
  - D on a 2025 peak season Saturday.
- With the Intersection Rodanthe Terminus, a traffic signal would be provided at the intersection with existing NC 12. With the signalized intersection, this option would carry NC 12 traffic at a desirable level of service during forecast peak season weekday traffic for 2025. The level of service with the Intersection Rodanthe Terminus at the signalized intersection would be:

- B on a 2025 peak season weekday;
- D on a 2025 peak season weekend; and
- E on a 2025 peak season Saturday.

The signalized intersection with the Intersection Rodanthe Terminus was assumed to include a single exclusive left-turn lane for northbound NC 12 traffic turning to reach the proposed bridge and a single exclusive right-turn lane for southbound traffic turning to continue south on NC 12. Level of service (LOS) B on a 2025 peak season weekday exceeds the NCDOT's and the FHWA's LOS objectives (i.e., LOS D) for a signalized intersection on a peak season weekday in a location with a seasonal population. Dual exclusive left turn lanes for northbound NC 12 traffic would improve conditions to LOS D for the 2025 peak season Saturday period with the Intersection Rodanthe Terminus. (See Section 1.5.7 for a definition of the LOS measures and additional discussion of LOS along NC 12.)

- The Curved Rodanthe Terminus would require the addition of a service road to maintain road access to adjoining properties. A service road is not needed with the Intersection Rodanthe Terminus.

2.9.5 Construction Procedures

2.9.5.1 Likely Construction Procedures

Construction of the proposed bridge would involve primarily the assembly of large precast concrete units. Precast units would be manufactured at a precast plant and shipped to the construction site. Smaller components could be delivered by truck or barge. The least costly method for shipping all parts probably would be by barge.

Substructure

When building the substructure (the portion of the bridge that supports the bridge spans and deck), the easiest way to move erection cranes from place to place is by attaching them to a barge and moving the barge from place to place. In general, the substructure would be erected by a crane on a barge. Generally, Oregon Inlet's bottom would only be dredged in water depths less than 6 feet (1.8 meters) where SAV is not present. This situation occurs for approximately 8 miles (12.8 kilometers) of the project's 17.5-mile (28.2-kilometer) length), primarily near the southern terminus and in the Oregon Inlet area. Where dredging is needed, the dredging would be to a depth of 8 feet (2.4 meters) to 10 feet (3.0 meters) to provide more flexibility for construction barge operations and to reduce the frequency of any maintenance dredging (since sand could shift and begin to fill in the dredged area over the course of construction).

Where SAV is present, erection equipment would be placed on a work bridge (a temporary short-span, low-elevation structure) to avoid dredging and directly affecting the SAV. Assembly of the work bridge would be span-by-span using top-down construction. In top-down construction, the last span built is used by construction equipment to place the piers, girders, and decking for the next span.

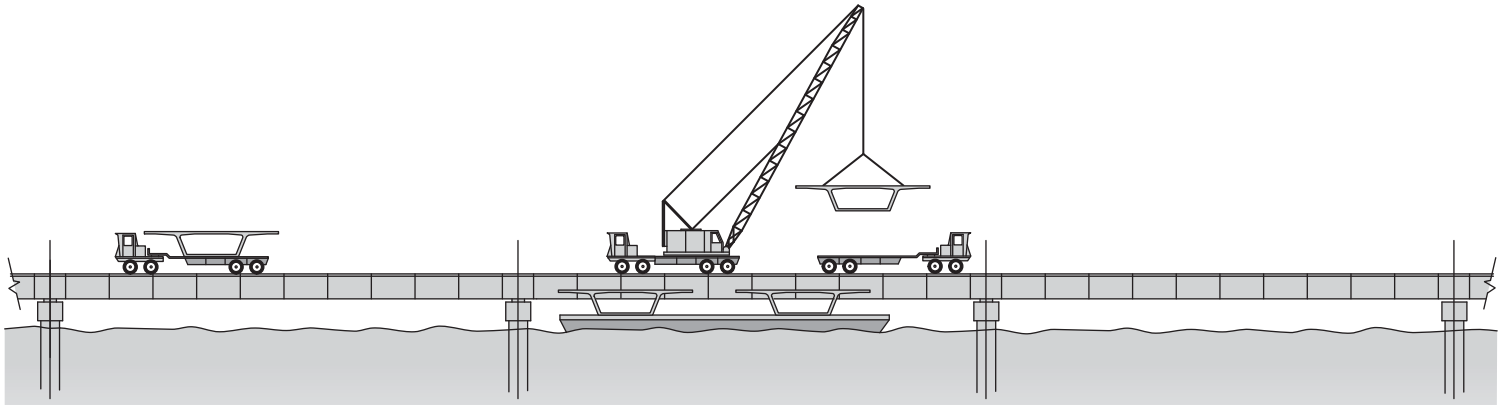
Disturbance to the sound bottom below would be caused by pile-driving operations at work bridge pier locations, ongoing construction operations, and equipment maintenance. On land, erection equipment would operate adjacent to this proposed bridge.

Superstructure

Assuming a segmental box girder superstructure, the superstructure (or spans) outside of the navigational zone (140 to 150 feet [42.7 to 45.7 meters] long) could be built using a "span-by-span" placement of the segmental boxes. Segments could be delivered to, and stored at, a staging area (work platform or anchored barges) in Pamlico Sound and then transported along the constructed sections of the permanent bridge to their final destinations where the bridge would be erected using an erection truss (see Figure 2-15 and Figure 2-16). Two such staging areas of about 5.0 acres (2.0 hectares) in size likely would be used. A similar approach would be used if concrete girders ("I" shape) are used. Span lengths in this case would be shorter, perhaps 120 feet (36.7 meters).

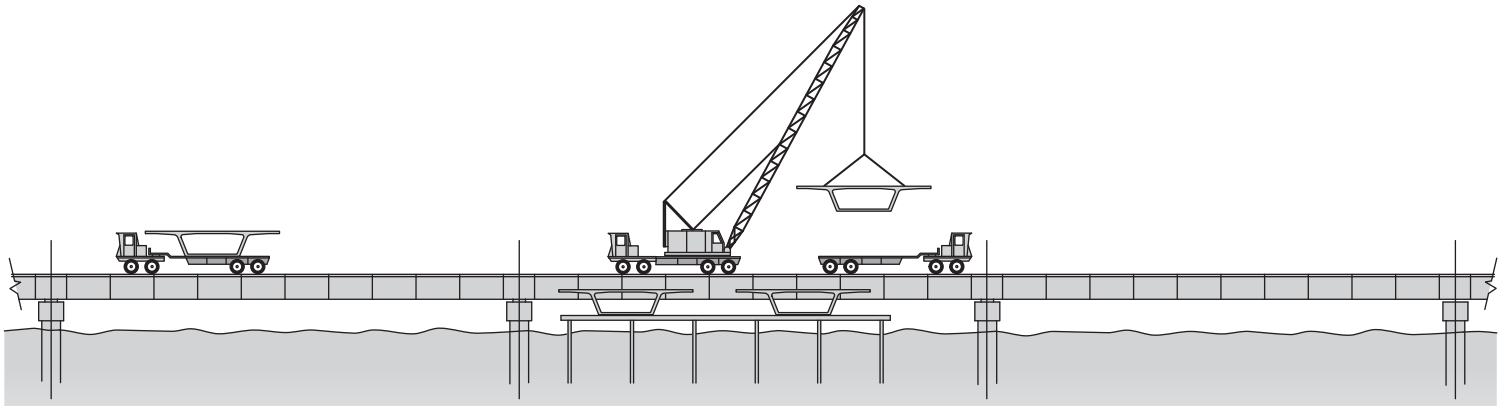
Segmental box girder spans within the navigation zone (minimum 200 feet [61 meters] of horizontal clearance) would be erected by "balanced cantilever" construction. Balanced cantilever construction would involve the erection of box-girder segments beginning at a pier and then erecting segments alternating each side of the pier as segments are added. The cantilevers would be built and joined ultimately with the cantilever that has been constructed previously on the adjoining piers. An overhead gantry, beam and winch on the bridge deck, or barge-mounted cranes could be used to erect the segments. See Figure 2-17 for an illustration of these balanced cantilever erection methods.

If an overhead gantry is used, segment delivery could be made over the completed portion of the bridge, to the back of the gantry, where the gantry would lift and transport the segment for erection. The size of the project and speed of erection could justify the investment to fabricate a gantry if the contractor chooses to make such an investment. With the beam-and-winch method of construction, segment delivery would be by barge.



On land, span erection equipment would operate adjacent to the proposed bridge.

2.9.5.2 Planned Construction Timing



The NCDOT plans to let the proposed bridge project for construction as a "design-build" project in 2009. As a design-build project, contractors would submit bids to both design and build the bridge based on specifications and other requirements defined by the FHWA and NCDOT.

Construction of the bridge would begin while portions of the design are still underway. This process would reduce the time needed to design and build the project. Initial construction activities would be completed over a four year period.

Construction could take place throughout the year. Bridge construction operations could likely take place 24 hours a day so that the bridge could be opened to traffic in 2013. Severe weather or water conditions could stop construction temporarily. If requested by permitting agencies, subaqueous (i.e., underwater) construction activities and dredging within the deepest portions of the Oregon Inlet could be reduced or avoided during the spring seasonal migration period.

Figure 2-17

2.10 Description of Parallel Bridge Corridor Alternatives with NC 12 Maintenance (Selected for Detailed Study)

The Parallel Bridge Corridor with NC 12 Maintenance alternatives include a replacement bridge that begins at the southern terminus of Bonner Bridge on Hatteras Island. The bridge would extend north across Oregon Inlet for approximately 2.7 miles (4.3 kilometers), ending near the northern terminus of Bonner Bridge on Bodie Island. The NC 12 maintenance component would keep NC 12 open from the community of Rodanthe to the Oregon Inlet bridge's southern terminus, a distance of approximately 12.5 miles (20.1 kilometers).

Five alternatives for the NC 12 maintenance component are considered. They are:

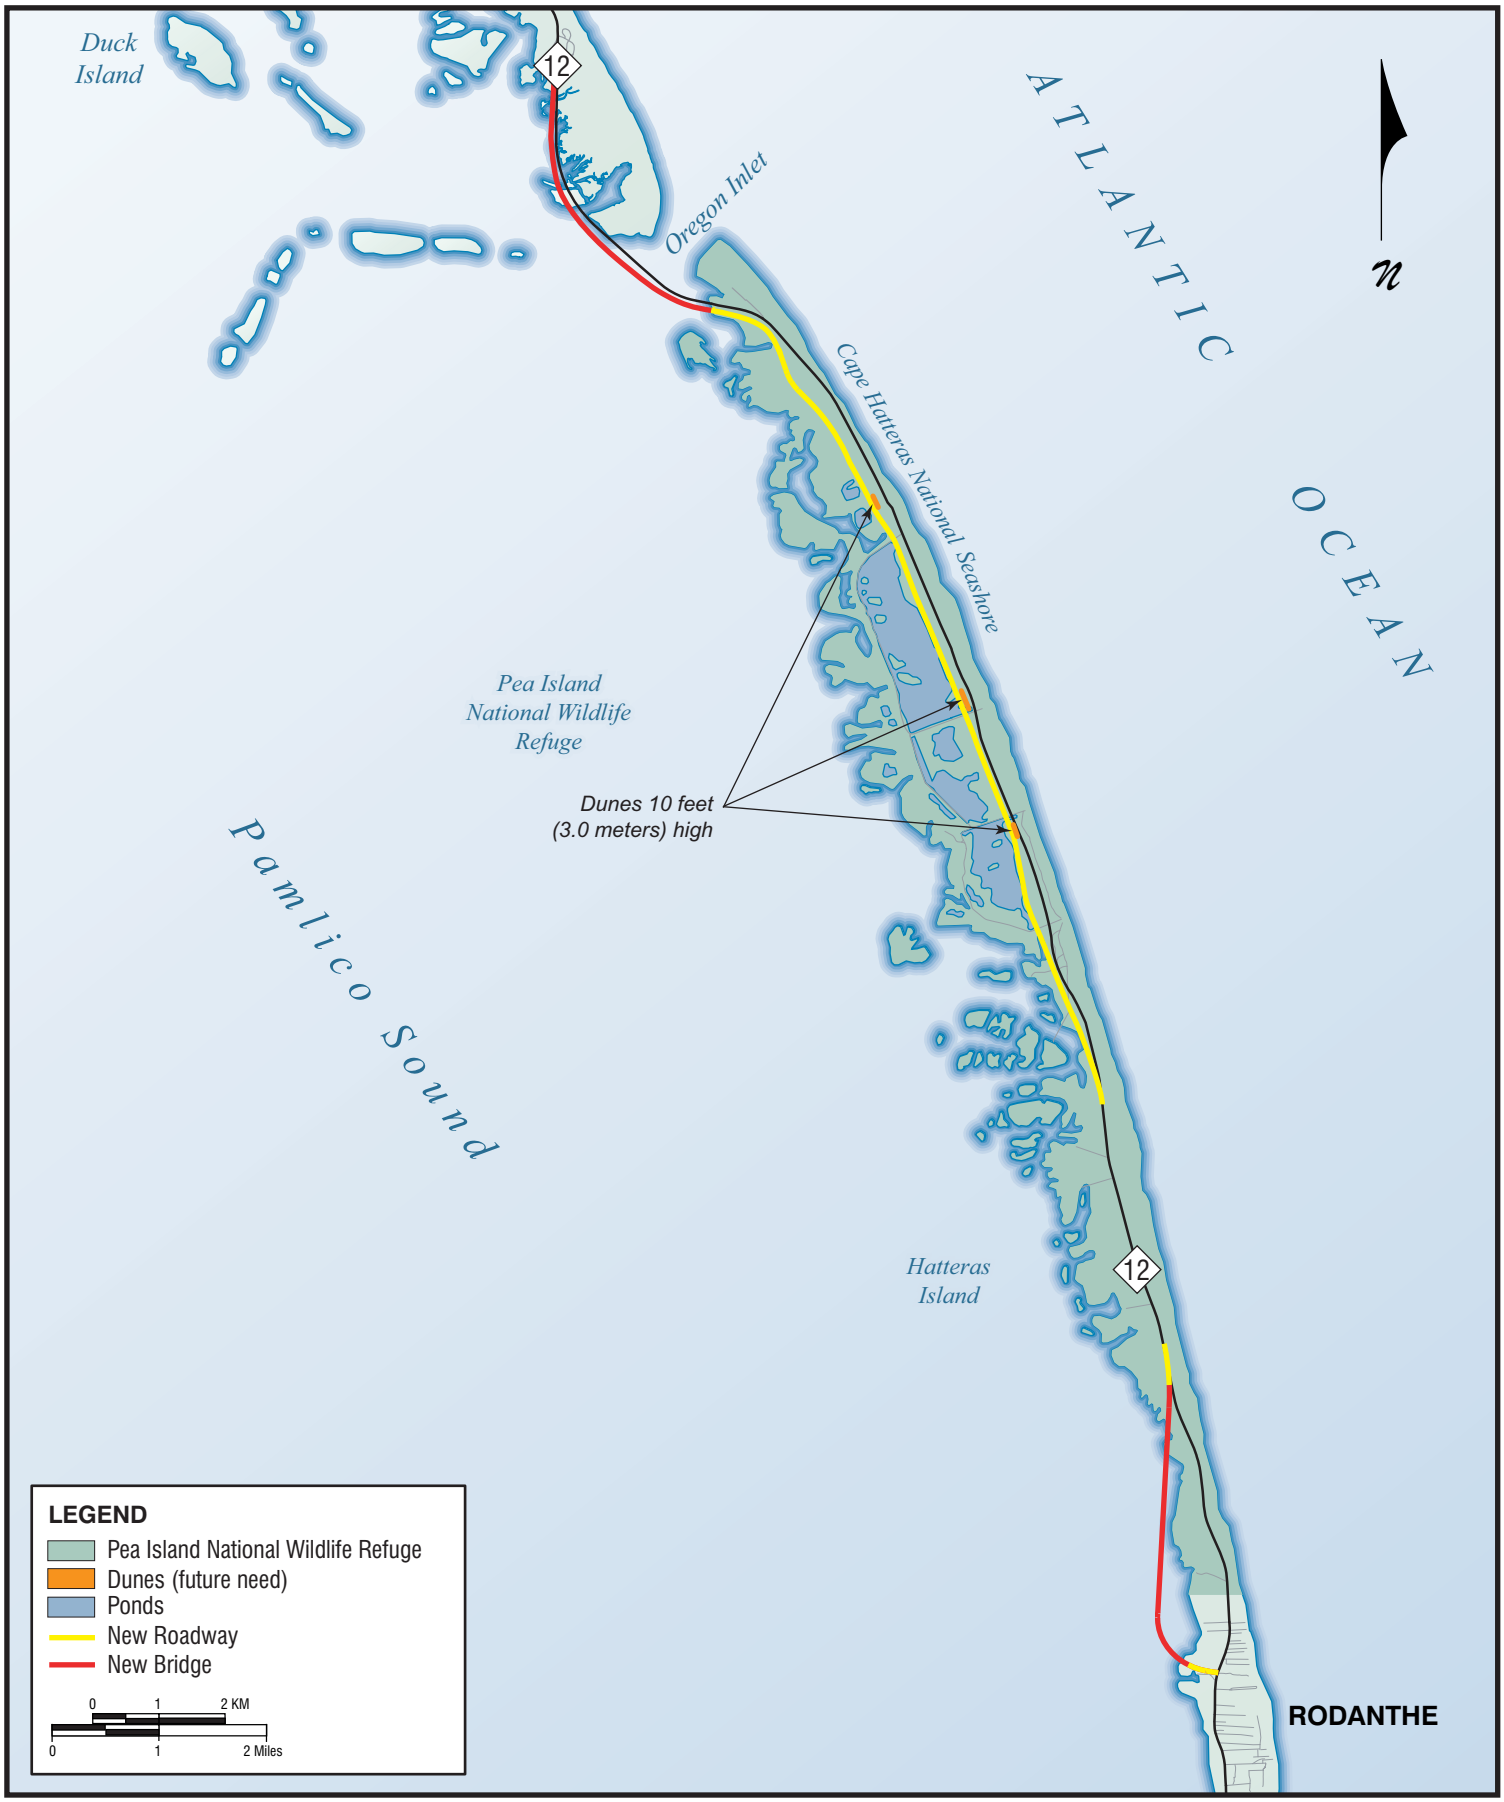
- Nourishment. Maintenance of NC 12 in the existing easement through beach nourishment with dunes at several locations;

- Road North/Bridge South. NC 12 relocation to the west as a road in the northern half of the Refuge and on a bridge in the Rodanthe area; All Bridge. NC 12 relocation to the west on a bridge both in the northern half of the Refuge and in the Rodanthe area;

- Phased Approach/Rodanthe Bridge (Preferred). Maintenance of NC 12 in the existing easement by building a bridge as needed in the existing easement; and

- Phased Approach/Rodanthe Nourishment. Maintenance of NC 12 in the existing easement by building a bridge as needed in the existing easement, except in Rodanthe where NC 12 would be maintained in the existing right-of-way through beach nourishment.

The Parallel Bridge Corridor with NC 12 Maintenance alternatives are illustrated in Figure 2-18 to Figure 2-21.



Although the NC 12 Maintenance alternatives are described and addressed in this FEIS as five separate alternatives, their components could be mixed and matched geographically along the length of NC 12 to create other variations. For example, NC 12 could be relocated on a road immediately south of a new Oregon Inlet bridge and relocated on a bridge in the area of the large ponds within the Refuge and at Rodanthe. NC 12 also could be protected by beach nourishment in the northern part of the Refuge and relocated on a bridge in the Rodanthe area. The Bridge South component of the Road North/Bridge South Alternative could be used in place of the Phased Approach alternatives' components at the south end of the Refuge and at Rodanthe. Other combinations are also possible. As such, the assessment of the five NC 12 Maintenance alternatives is representative of all possible combinations of their components.

The two Phased Approach alternatives (including the Preferred Alternative) are described and addressed in this FEIS with specific locations and lengths for the phases. These details could be adjusted based on funding availability and changing coastal conditions within the project area, recognizing the uncertainty of predicting future shoreline conditions. For example, if a storm related breach were to occur, or if shoreline erosion accelerated or decelerated in a particular location, implementation of any individual phase could be accelerated or delayed. Opportunities

PARALLEL BRIDGE CORRIDOR WITH PHASED APPROACH

Figure 2-21

for phasing the NC 12 maintenance component of the Parallel Bridge Corridor alternatives assessed in the FEIS are presented in Section 2.10.2.5 under "Opportunities for Phasing the Road North/Bridge South and All Bridge Alternatives."

The subsections that follow describe first anticipated characteristics and construction procedures associated with a new Oregon Inlet bridge in a parallel corridor and then anticipated NC 12 Maintenance alternatives characteristics and construction procedures, including phasing for the Phased Approach alternatives (including the Preferred Alternative). Like the Pamlico Sound Bridge Corridor, safety features would be incorporated into the bridges associated with the Parallel Bridge Corridor alternatives. The All Bridge Alternative and the Phased Approach alternatives (including the Preferred Alternative) would include turnouts for disabled vehicles, as needed, with a maximum distance between these turn-outs of 3 miles (4.8 kilometers). ITS devices would be considered for all bridges.

The design features and approaches to construction described in this FEIS for the Parallel Bridge Corridor with NC 12 Maintenance alternatives were developed based on the best available data at the time. These descriptions were prepared to provide the readers of this FEIS with an understanding of the expected characteristics of each alternative and for use in estimating project cost, level-of-service, and environmental impact. It is assumed that the specific design features (including, bridge span types and arrangements) and approaches to construction described here could change during final project design or by the design-build contractor, preparation of permits, and the development of final mitigation measures. It is not anticipated, however, that such refinements would result in substantial changes to project costs or impacts, or changes to the commitments contained in the Project Commitments section of this FEIS.

Demolition and removal of Bonner Bridge and the disposal of parts of NC 12 are discussed in Section 2.11. Costs and funding for the alternatives associated with both bridge replacement corridors evaluated in detail in this FEIS are discussed in Section 2.12. Environmental protection during construction of the proposed project is discussed in Section 2.13. Permits and approvals are discussed in Section 2.14.

2.10.1 Oregon Inlet Parallel Bridge Characteristics

The proposed Oregon Inlet bridge would be approximately 2.4 to 2.7 miles (3.9 to 4.3 kilometers) in length. Its location is illustrated in Figure 2-10, and in Figure 2-18 to Figure 2-21. The proposed bridge would:

- Begin at or near the southern terminus of Bonner Bridge. With the Nourishment Alternative and the Phased Approach alternatives (including the Preferred Alternative), the bridge would terminate within the existing NC 12 easement on Hatteras Island. With the Road North/Bridge South Alternative, it would enter Hatteras Island 260 feet (79.2 meters) west of Bonner Bridge. With the All Bridge Alternative, it would enter Hatteras Island 350 feet (106.7 meters) west of Bonner Bridge.

- Follow a curved alignment immediately west of Bonner Bridge. The bridge would cross the existing navigation channel for vessels using Oregon Inlet approximately 500 feet (152.4 meters) west of Bonner Bridge. The bridge would cross Bridge to Old House Channel, commonly known as "the crack" where the channel closely parallels Bonner Bridge.

- Terminate at the Bonner Bridge terminus on Bodie Island and follow a route between Bonner Bridge and the parking lot for the Oregon Inlet Marina and Fishing Center.

2.10.1.1 Horizontal Alignment

The Oregon Inlet bridge would consist of a southern approach roadway, a southern approach bridge, main bridge, a northern approach bridge, and a northern approach roadway. These components would be the following lengths:

	Nourishment	*Road North/ Bridge South*	*All Bridge*	*Phased Approach**
Southern Approach Roadway	1,428 feet (435 meters)	1,500 feet (457 meters)	0 feet (0 meters)	0 feet (0 meters)
Southern Approach Bridge	1,370 feet (418 meters)	700 feet (213 meters)	800 feet (244 meters)	0 feet (0 meters)
Main Bridge	9,270 feet (2,826 meters)	10,098 feet (3,078 meters)	10,131 feet (3,088 meters)	9,998 feet (3,047 meters)
Northern Approach Bridge	3,730 feet (1,137 meters)	3,730 feet (1,137 meters)	3,730 feet (1,137 meters)	3,730 feet (1,137 meters)
Northern Approach Roadway	3,295 feet (1,004 meters)	3,295 feet (1,004 meters)	3,295 feet (1,004 meters)	3,295 feet (1,004 meters)

*including the Preferred Alternative

The approach fills (pile of soil upon which the approach roadway is built) would be between the natural ground and a point where the bottom of the bridge girder can be a minimum of 3 to 6 feet (0.9 to 1.8 meters) above the ground. This limited amount of distance between the ground and the bottom of the girder is needed for maintenance, so girder support bearings are kept above the ground.

2.10.1.2 Design Characteristics

This section discusses key Oregon Inlet bridge design characteristics related to design criteria, traffic service, wave energy, storm surge, scour protection, navigational clearances, ship impact, superstructure types, foundation types, use of fill, access to recreation opportunities, and utility relocation. Unless specified, the design characteristics of the Oregon Inlet bridge would accommodate all five NC 12 Maintenance alternatives.

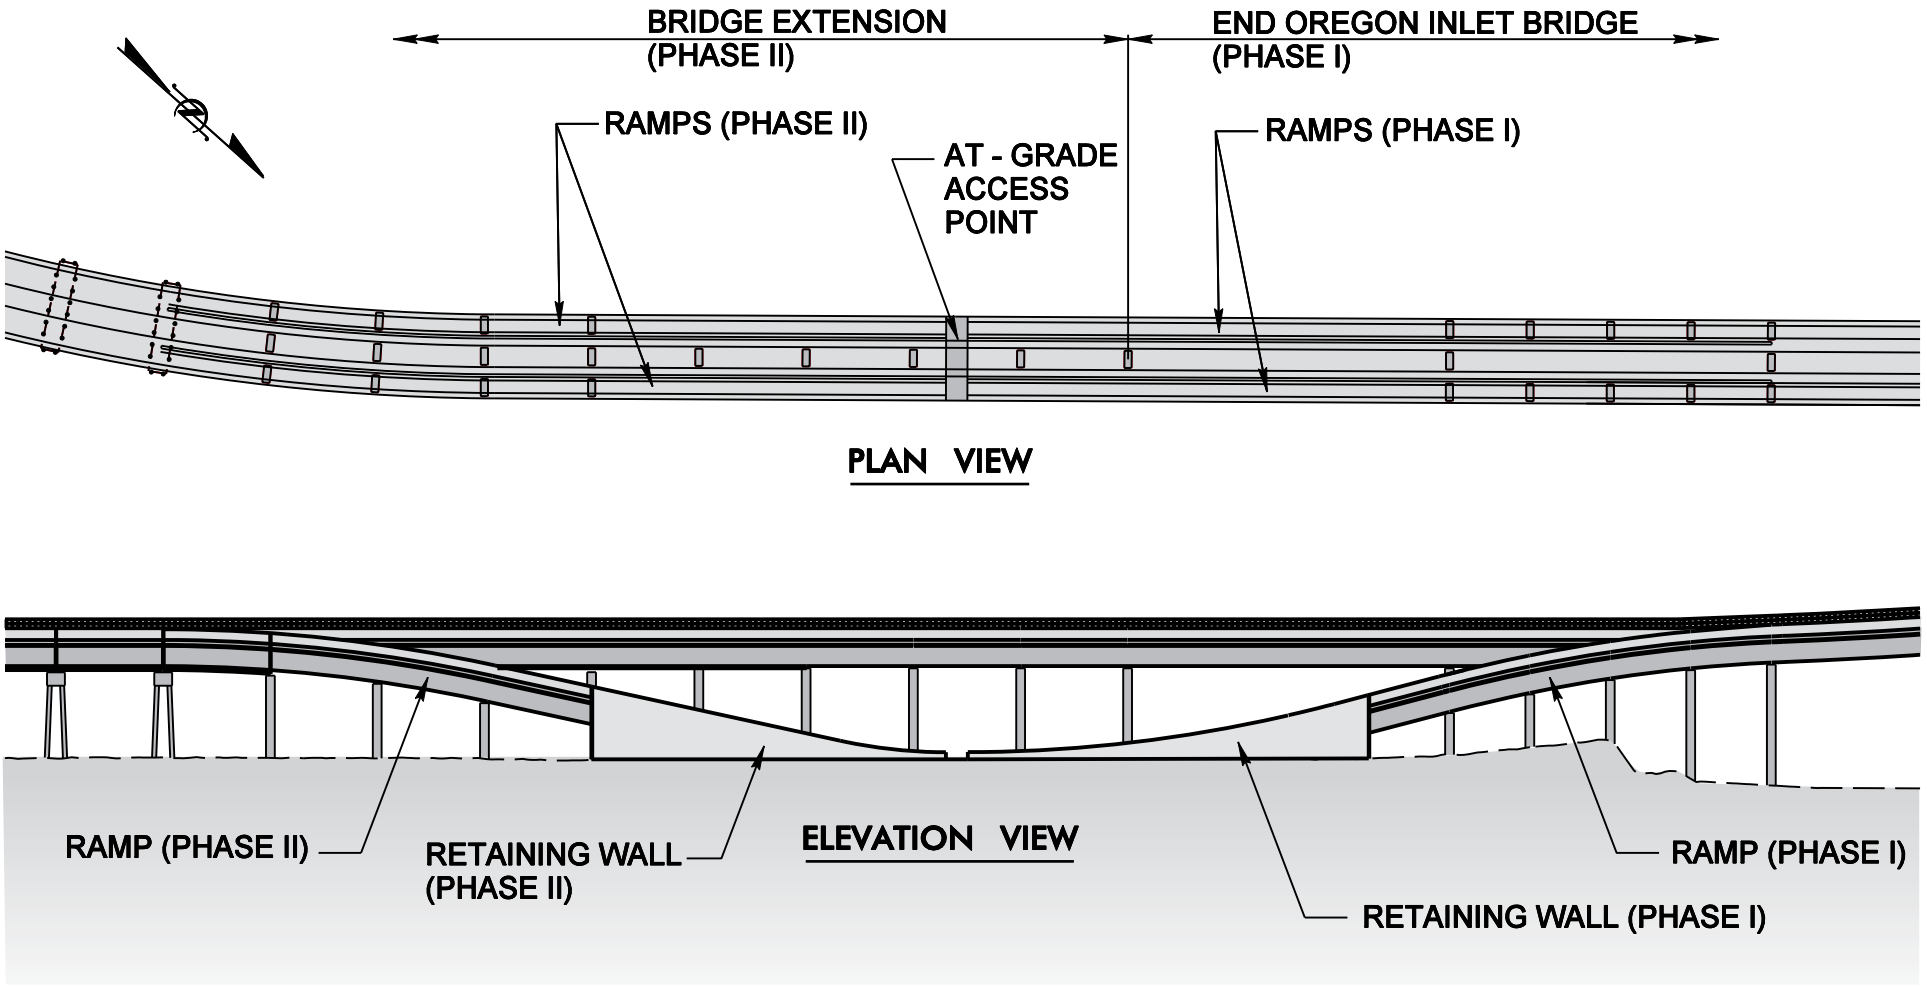
Design Criteria and Traffic Service

As with the bridge in the Pamlico Sound Bridge Corridor (described in Section 2.9.2), the typical section of the new Oregon Inlet bridge would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders, for a 40-foot (12.2-meter) clear roadway width. This bridge's typical section is illustrated in Figure 2-13. The total outside width of the bridge would be 42.6 feet (13.0 meters), with the additional 2.6 feet (0.8 meter) being required to accommodate the bridge rails.

The proposed bridge shoulders would accommodate bicyclists and pedestrians more safely than the existing 2 feet (0.6 meters) of clearance and allow room for movement around stranded vehicles and accidents. A bicycle-safe bridge rail would be utilized. The 40-foot (12.2-meter) clear roadway width on the bridge could allow for the temporary emergency designation of three lanes during evacuations, with two lanes of traffic moving off the island.

The approach roadway (on fill) to the bridge would have 8-foot (2.4-meter) shoulders (4-foot [1.2-meter] paved) and provide 8 feet (2.4 meters) of clearance from the edge of the travel lane to the face of the guard rail. The 4-foot (1.2-meter) paved shoulders on the approach roadway were assumed to taper to match the 6 feet (1.8 meter) of lateral clearance on each side of the replacement structure (see Figure 2-14).

With the Phased Approach alternatives (including the Preferred Alternative), the bridge would not come down to grade at its south end. Ramps would bring travelers down to NC 12 until the bridge is extended as a part of Phase II (see Figure 2-22). After the completion of Phase II, these ramps would remain and be paired with two more ramps at the same location to provide access to the northern end of Hatteras Island.



Wave Energy, Storm Surge, and Scour

Scour is a characteristic of the dynamic nature of the Oregon Inlet, and it has the potential to threaten crossing structures. For this FEIS, the following scour protection depths were assumed to be used with the Oregon Inlet bridge:

- Southern bridge approach—61.0 to 70.9 feet (18.6 to 21.6 meters) below mean sea level;
- Main bridge—105.0, 109.9, and 84.0 feet (32.0, 33.5, and 25.6 meters) below mean sea level with the lesser depths at the south and north ends of the main bridge, respectively; and
- Northern bridge approach—55.1 to 63.0 feet (16.8 to 19.2 meters) below mean sea level.

The destruction of many bridges in the Gulf Coast region resulting from Hurricane Katrina demonstrates the significance of wave and water forces on bridges. The effects of wave energy, storm surge, and scour would be accounted for in the Oregon Inlet bridge final design, as well as in the final design of the bridges associated with the NC 12 maintenance components over or expected to be over waterways, which are described in Section 2.10.2. This would be done in accordance with the latest version of the American Association of State Highway and Transportation Officials (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications, recommendations outlined by the FHWA-AASHTO Wave Task Force, and NCDOT requirements. The Wave Task Force is developing interim guidance for quantifying wave forces on bridges, structural design approaches for wave forces, and deployment of countermeasures for existing bridges. The task force's report titled "Guide Specifications for Bridges Vulnerable to Coastal Storms" was approved by the AASHTO Subcommittee on Bridges in May 2008, but is still waiting to be published, so there could be modifications to the guidance (e.g., technical queries, editorial changes, etc.) before the report is published. These AASHTO and NCDOT specifications and requirements also would apply to the Pamlico Sound Bridge Corridor.

Foundation and substructure elements for project bridges would be designed with the assumption that no new revetments would be constructed at the time the bridges are initially built and that no new revetments would be constructed in the future. It is well documented that the Oregon Inlet is in a dynamic environment that produces highly complex hydraulic conditions. In addition, the erosion of the existing shoreline south of the Oregon Inlet presents difficulty in predicting future conditions as related to hydraulic, geotechnical, and structural engineering design for the new bridges associated with the Parallel Bridge Corridor alternatives. Therefore, hydrodynamic studies and analyses of coastal processes that are required to supplement or to provide parameters for the structure design would be developed in accordance with the latest edition of the USACE Coastal Engineering Manual. The new analyses would be accomplished as part of the final

OREGON INLET BRIDGE SOUTHERN TERMINUS WITH THE PHASED APPROACH ALTERNATIVE

Figure
2-22

design of the Oregon Inlet Bridge and other bridges over or expected over waterways. These analyses would include a site-specific hydrologic model to assist in determining design parameters related to scour and to predict coastal erosion.

These analyses also would incorporate, with the Parallel Bridge Corridors alternatives that include bridges through the northern part of Hatteras Island, the potential for terminal groin removal after bridges are completed or the groin's flanking. The hydrologic, hydraulic and scour analyses would be developed in accordance with the latest relevant FHWA guidelines including, but not limited to, HEC-18 Evaluating Scour at Bridges, HEC-25 Tidal Hydrology, Hydraulics and Scour at Bridges, and NCDOT requirements for bridges over waterways. The bridges over or expected to be over waterways would require hydraulic analysis using a FHWA accepted two-dimensional hydrodynamic model such as FESWMS-FST2DH. In the case of a future inlet developing and remaining open in the Phase II to IV bridge areas, the complexity of the hydraulics of a two (or more) inlet system would require large scale 3D modeling of the hydrodynamics, sediment transport and morphological change in order to quantify the interaction of the multi-inlet system and establish design conditions.

Plans developed in accordance with NCDOT requirements would provide computations of scour critical elevations for all bridge foundations within or expected to be within waterways. These critical elevations would be used by inspectors to gauge the severity of scour as the scour conditions are monitored over the service life of the bridge.

Corrosive Environmental Conditions

Coastal environmental conditions, including but not limited to, high wind speeds, brackish water and air, humidity, wetting/drying cycles, and storm conditions would be factored into the final design and detailing of the Oregon Inlet bridge and other bridges associated with the Parallel Bridge Corridor alternatives. Bridge components would be designed for these conditions.

Navigational Clearances

A new bridge across Oregon Inlet must take into account the migratory nature of the navigational channel. Thus, the bridge should provide the required navigational clearances at spans within the range of probable channel locations. The proposed bridge would include a series of navigational spans across Oregon Inlet, a distance up to 5,000 feet (1,524 meters) with a minimum vertical clearance of 75 feet (22.9 meters). Spans in the navigation zone would have a minimum of 200 feet (60.1 meters) of horizontal clearance.

The length of the navigation zone (approximately 3,300 feet [1,006 meters]) with the Phased Approach alternatives (including the Preferred Alternative) would be less than the Oregon Inlet bridge associated with the other Parallel Bridge Corridor alternatives (up to 5,000 feet [1,524 meters]). The shorter distance with the Phased Approach alternatives (including the Preferred Alternative) is necessitated by the inclusion of the ramps noted above to provide access to the north end of Hatteras Island from the alternative's bridges.

Coordination with the US Coast Guard and USACE would facilitate the establishment of location(s) for navigation spans, channels, and clearances. The location(s) of the navigation span(s) would be considered when designing for potential vessel collision.

Ship Impact

A hopper dredge was selected during the 1995 bridge type study as the design vessel for ship impact. Design for vessel collision would be in accordance with the latest version of the

AASHTO LRFD Bridge Design Specifications, the AASHTO Guide Specification and Commentary for Vessel Collision Design of Highway Bridges, and NCDOT requirements. The effects of scour also would be accounted for when designing for vessel collision in accordance with the LRFD Bridge Design Specifications and NCDOT requirements.

Superstructure Types

In general, the bridge type assumed for this corridor was determined by navigational span requirements, ship impact requirements, scour requirements, and constructability. Long-span precast concrete segmental box girders built using the balanced cantilever construction method could be used.

With the Parallel Bridge Corridor with Nourishment Alternative, the new Oregon Inlet bridge would end in the existing Bonner Bridge easement. In order to accomplish this, it is assumed that the new bridge would be built over the top of the old bridge for the new bridge's last two southern spans. The foundation and piers of this part of the new bridge could straddle Bonner Bridge. The superstructure could be placed on a straddle cap that would span the piers on either side of Bonner Bridge. The Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) also would end in the existing Bonner Bridge easement. In this case, it was assumed that a traffic maintenance bridge would be used to accomplish this objective. Thus, unlike the Nourishment Alternative, no special superstructure configuration would be needed or was assumed at the south end of the bridge. These approaches are two possible options for building the southern end of a new Oregon Inlet Bridge in the same easement as Bonner Bridge. Another option could prove prudent during project design.

Foundation Types

Based on the scour and ship impact criteria, the foundations for the Oregon Inlet Bridge would be both deep and substantial in construction. Large piles would be required. Based on a design prepared in 1999, for the main bridge 66-inch (165-centimeter) diameter pre-stressed concrete cylinder piles are assumed in the impact assessment. Sixteen to 24 piles were assumed to be used for each foundation on the main bridge, and eight were assumed to be on the approach spans. These piles could be placed by a combination of jetting and driving. A footing would be cast just above the waterline on the cylinder piles. A precast segmental box column was assumed to be placed on the footing to support the superstructure. The footing size for the main bridge was assumed to be 80.1 feet (24.4 meters) wide by 52.5 feet (16.0 meters) long.

In addition to the requirements established in the latest version of the NCDOT's Structure Design Manual and the latest AASHTO LRFD Bridge Design Specifications, the final design pile lengths would be determined for both the Oregon Inlet bridge and other bridges associated with the Parallel Bridge Corridor alternatives based on the following:

- Results from a hydrologic, hydraulic, and scour analyses.
- Results from a coastal engineering model that predicts subsurface elevations in the vicinity of the bridge at the end of the bridges' theoretical design life.
- Subsurface exploration program.
- Structural design requirements including, but not limited to, vessel collision, scour and water loads.

- Results from bridge foundation and substructure analyses that include the effects of soil-structure interaction behavior. Finite element analysis software intended to analyze soil-structure interaction such as FB-Pier (Florida Pier).

As described above for the Oregon Inlet bridge, it is anticipated that different pile lengths would be required at different reaches along all bridge alignments. The bridges would be sub-divided to achieve economical foundation designs and pile lengths at different regions along the structure. The range of predicted scour depths could be used as a means of sub-dividing the zones of the structure. The pile lengths also would be determined assuming that no future revetments or stabilizing measures would be constructed over the design life of the bridges.

Use of Fill

As with all bridges, at each end of the bridge in this corridor fill would be used instead of structure for the approach roads between the natural ground and a point where the bottom of the bridge girder can be a minimum of 3 to 6 feet (0.9 to 1.8 meters) above the ground. The two approach road fills would have a continuous grade downward from each bridge abutment to natural ground. A maximum 3:1 slope would occur on Hatteras Island. Fill slopes generally would be 4:1 on Bodie Island. With the Phased Approach alternatives (including the Preferred Alternative), a fill slope would be used only at the Bodie Island (north) end of the bridge as noted above.

Access to Recreation Opportunities

A connection from NC 12 to the unpaved beach access road, which is south of the Oregon Inlet Campground on Bodie Island, would be provided.

Bonner Bridge has catwalks that are used by fishermen. For safety reasons, access via catwalks on a new bridge in this corridor is not assumed because the height of the new bridge would put the catwalks at least 40 feet (12.2 meters) above the water. The height of such a catwalk increases the likelihood of serious, if not fatal, injuries resulting from falls.

Opposition to discontinued fishing access also was expressed at the public hearings because fishing is a popular tourist recreational activity on this part of Hatteras Island. The NPS and the USFWS have indicated that their objective is to provide for fishing access at the north end of Hatteras Island at Oregon Inlet but the access does not have to be provided from catwalks mounted on the new bridge. One viable approach (except with the Nourishment and Phased Approach alternatives [including the Preferred Alternative]) appears to be leaving a portion of existing Bonner Bridge for fishing. A "boardwalk" under and around the new bridge also is a possible option with all the Parallel Bridge Corridor alternatives. A boardwalk would be on top of the riprap that currently blankets the northern shore of Hatteras Island.

With the Phased Approach alternatives (including the Preferred Alternative), it was assumed that a temporary bridge approximately 2,600 feet (793 meters) long for maintenance of Bonner Bridge traffic would be built east of Bonner Bridge to divert NC 12 traffic during construction off the southern end of the new Oregon Inlet bridge. Once construction of the new Oregon Inlet bridge is completed, the traffic maintenance bridge could be retained as a fishing pier to replace the fishing catwalks on Bonner Bridge. The new fishing pier would be much wider than the catwalks (26 feet [7.9 meters] versus 4.5 feet [1.4 meters]), providing fishermen with more room to move about than on the current catwalks.

Accommodating fishing from the terminal groin is not considered a viable option. Fishing from the groin is considered very dangerous because of the rapid currents adjacent to the groin, as well as the uneven surface of the groin.

Utility Relocation and Intelligent Transportation Systems Devices

Telephone and power cables could be placed on the new bridge to replace those now on Bonner Bridge. As with the Pamlico Sound Bridge Corridor, during final design the NCDOT would consider implementation of ITS devices (see Section 2.9.2) to provide motorists with road condition information in the NC 12 corridor and on the replacement bridge.

2.10.1.3 Construction

Construction of an Oregon Inlet bridge could take up to 3.5 years to complete. The Oregon Inlet bridge could be completed in less time than a Pamlico Sound Bridge because of its shorter length. Like the Pamlico Sound Bridge Corridor, the NCDOT plans to let a Parallel Bridge Corridor project for construction as a "design-build" project in 2009. Theoretically, construction could take place throughout the year. Severe weather or water conditions could stop construction temporarily.

The following sections describe the construction techniques for the Oregon Inlet bridge and NC 12 Maintenance alternatives assumed in the assessment of impacts in Chapter 4. Unless specified, the construction techniques of the Oregon Inlet bridge would apply to all five NC 12 Maintenance alternatives.

For the Preferred Alternative, the specific methods used in the construction of the project would be determined by the design-build contractor. Those methods would be consistent with environmental protection requirements established by FHWA and NCDOT based on the impact mitigation programs, and project commitments presented in Chapter 4 and the Project Commitments sections of this FEIS, as well as the requirements of environmental regulatory agency permits.

Manufacture and Transport of Components

Construction of an Oregon Inlet bridge in the Parallel Bridge Corridor would involve primarily the assembly of large precast concrete units. Precast units, weighing up to 100 tons (90.7 metric tons), would be manufactured at a precast plant and shipped to the construction site. The substructure also would have precast column and cap components. The footings would be cast-in-place concrete. Materials for the footings would be delivered by truck and/or barge. North Carolina highway regulations include a maximum allowable shipping length; parts exceeding this length would be shipped by barge. The least cost method for shipping all parts probably would be by barge.

Construction of Proposed Structure

The bridge superstructure would be built utilizing the balanced cantilever construction method from barges and a haul road (see Figure 2-17). Top-down construction and construction from a work bridge are not practical (as discussed later in this section).

For the main bridge, the method of construction would be from barge. Barges and fixed cranes must be used to build the main bridge because the pre-cast piles would be too heavy to be lifted into place by crawler cranes. When building over a water body, the easiest way to move a fixed crane from place to place is by attaching it to a barge and moving the barge from place to place.

Where the southern approach of the bridge passes over Hatteras Island, the smaller pre-cast piles would be used to avoid digging a canal into the Island. With smaller piles on land, lighter, more maneuverable equipment operating on the ground can be used. Construction of the southern end of the bridge under the Nourishment Alternative and the Phased Approach alternatives (including the Preferred Alternative) would have unique characteristics because the southern approach would be built in the existing Bonner Bridge easement. Thus, in the case of the Nourishment

Alternative a temporary detour road was assumed to be used to move traffic out of the existing easement so the new approach could be built. In the case of the Phased Approach alternatives (including the Preferred Alternative), a traffic maintenance bridge within the existing NC 12 easement and parallel to the new bridge was assumed.

For the northern approach, construction would likely involve temporary construction of a haul road on geotextile fabric. Here foundations would be lighter and crawler cranes operating on a haul road could be used to erect the precast piles.

Main Bridge. Construction of the substructure for the main bridge can be accomplished best by working directly from barges. Material would be delivered by barge. Additional barges would be needed for construction platforms and construction equipment such as cranes, forms, and other equipment. Pile leads attached to cranes would be used as guides for precast concrete pile installation. Piles would be unloaded from the barges and placed into the leads. Different methods could be used to install the piles to a predetermined elevation and set by impact drivers to the final pile tip elevation. The piles would be cut just above the water line and concrete footings cast on them.

The inlet bottom would be dredged wherever the water depth is less than 6 feet (1.8 meters). Dredging also likely would occur behind Bodie Island up to the point where the north approach begins. The proposed channel would be 8 feet (2.4 meters) deep and approximately 120 feet (36.6 meters) wide. The components of the segmental box girder superstructure also would be brought to the construction site by barges. Balanced cantilever construction of the superstructure would involve erecting box-girder segments beginning at a pier and then alternatively erecting segments on each side of the pier. The cantilevers are built and joined ultimately with the cantilever that has been constructed previously on the adjoining piers. An overhead gantry, beam and winch on the bridge deck, or barge-mounted cranes could be used to erect the segments (see Figure 2-17). If an overhead gantry is used, segment delivery could be made over the completed portion of the bridge, to the back of the gantry, where the gantry would lift and transport the segment for erection. The size of the project and speed of erection could justify the investment to fabricate a gantry if the contractor chooses to make such an investment. With the beam and winch method of construction, segment delivery would be by barge.

Southern Approach. Smaller piles would be used for the southern bridge approach of the Oregon Inlet bridge with all NC 12 Maintenance alternatives. Construction equipment used to install the south approach bridge foundations would operate on the ground.

Construction of the southern end of the bridge under the Nourishment Alternative and the Phased Approach alternatives (including the Preferred Alternative) would have unique characteristics because the southern approach would be built in the existing Bonner Bridge easement.

For the Nourishment Alternative, it was assumed that the last two or three spans of the south end of the Oregon Inlet bridge could be built over the final spans of Bonner Bridge so the Bonner Bridge easement in the Refuge could be used by the new bridge. A new right-of-way permit, therefore, would not be needed from the USFWS. If this approach is used, periodic short-term closings of NC 12, presumably at night and in the off-season, at a minimum during construction as new precast bridge components are maneuvered into position over or adjacent to Bonner Bridge. Once a component is placed, Bonner Bridge would be reopened to traffic until constructors are ready to place the next component. On land, where Bonner Bridge ends and the approach road to Bonner Bridge begins, a temporary detour would divert NC 12 traffic out of the existing easement.

For the Phased Approach alternatives (including the Preferred Alternative), it was assumed that a temporary bridge approximately 2,600 feet (793 meters) long would be constructed for maintenance of Bonner Bridge traffic. This temporary bridge would be built east of Bonner Bridge. The traffic maintenance bridge would allow the southern end of Bonner Bridge to be demolished so that the new Oregon Inlet bridge could be tied into existing NC 12 at the north end of Hatteras Island.

Northern Approach. At this time, construction from a temporary access road is anticipated to be the most flexible and economical way of constructing the north approach of the Oregon Inlet bridge and all NC 12 Maintenance alternatives. Piles for the approach span foundations would be placed from the haul road as described for piles for the main bridge. Crawler cranes would be used. The segmental box girder superstructure could be erected using crawler cranes on the temporary access road. The balanced cantilever construction method similar to that described previously for the main bridge spans would be used to erect the superstructure. Segments could be delivered to the work area on the temporary access road.

Pile Placement

The different types of foundation pile installation methods are described below. These descriptions apply both to the placement of piles with the Oregon Inlet Bridge, as well as the other bridges that comprise the Parallel Bridge Corridor alternatives. Each of these installation methods would result in different levels of disturbance and sediment release. Not all of these methods can be applied at all locations along the project. Decisions on methods for pile installation and on the exact procedures for minimizing pile placement impact would be developed by the design-build contractor based on criteria established by NCDOT. The methods for minimizing pile placement impacts below serve as examples of potential approaches.

Jetting. The technique of jetting-during-driving, is a pile installation technique that uses pressurized water that is "sprayed" from the tip of the pile as it is progressed through the ground. The jetting water erodes the soil immediately beneath the pile to allow the pile to pass easily through the subsurface material. Typically the jetting operation is terminated when the pile tip is approximately 5 feet (1.52 meters) above its target tip elevation. The pile is then mechanically driven ("seated") down to its final position. NCDOT only permits jetting-during-driving and not re-jetting, which is a different procedure.

The limit of the bottom disturbance around the pile(s) is a key factor in the extent of the impact of jetting on the surrounding area. One conclusion that research performed by North Carolina State University's (NCSU) Department of Civil, Construction, and Environmental Engineering (Characterization of Jetting-Induced Disturbance Zone and Associated Ecological Impacts, Report No. FHWA/NC/2006-09) yielded was that the diameter of the zone of disturbance, at all pile test locations, was found to be approximately equal to the jetted pile length (assuming material distribution is unaffected by currents). For example, if a pile was jetted for a distance of 30 feet (9.1 meters), the diameter of the disturbed area was measured to be approximately 30 feet (9.1 meters) centered on the pile. In addition, based on the field test results from the NCSU research, it was found that typically the volume of spoil was approximately equal to, or slightly greater than, the volume of the jetted pile.

In areas with swift water currents, such as in the Oregon Inlet, collection and disposal of jetting spoils would be very difficult. However, given the high volume of sediment transported through the inlet as a result of daily tidal action, it is anticipated that the volume of jetting spoils would be a small fraction of the volume of material moving in and out of the inlet on a daily basis.

In areas where the water is less turbulent, such as behind Bodie Island, collection and disposal of jetting spoils likely would be required to protect submerged aquatic vegetation and other ecological entities. For example, erosion control devices, including turbidity curtains, could be used around the piles during their installation to minimize and control sediment release and the limits of bottom disturbance. One means of collecting the spoils generated for disposal after jetting is complete would be a high powered vacuum system.

Spoils generated by jetting for bridges over Hatteras Island could be collected and disposed during the pile installation process by use of conventional excavation and hauling equipment on site since these piles would be installed on-land and not underwater. An approved disposal site for the spoil material would need to be identified by the design-build contractor. Erosion control measures such as silt fence and straw bales positioned around the pile location would assist in containing the jetting spoils to a limited area around the pile. It will be important that jetting spoils not leave the NC 12 easement in the Refuge. One option the contractor could use to avoid this is constructing a protective wall system adjacent to the existing right-of-way boundary at the foundations. The wall would deflect and prevent jetting spoils from leaving the easement.

Finally, to minimize the disturbed zone resulting from jetting spoils, a site-specific jetting program (pump flowrate, pump pressure, etc.) could be designed taking into account the actual soil characteristics at the site and the anticipated jetted pile lengths. Developing this type of program would likely involve performing testing at intermittent locations along the proposed project to categorize potentially different soil conditions.

Driving. The most conventional and least expensive pile installation technique is driving. Negligible bottom disturbance and sediment release results from pile driving operations. However, driving piles, regardless of the driving technique implemented, typically produces noise levels in the range of 82 to 105 dBA. Given the nature of the project area, high levels of noise during construction would not be desirable. Also, it probably not possible to drive large diameter cylinder piles, which are assumed for the Oregon Inlet bridge in this FEIS.

Drilling. Piles can be installed in pre-drilled holes (on land only) or drilled shaft foundations could be used. Drilled shaft spoils can be collected and disposed only when generated on land. The use of drilled shafts can result in lower noise levels than pile driving depending on the technique used to install the associated steel casings, but the volume of drilling spoils would be substantial.

Alternatives for Erecting the Bridge Behind Bodie Island.

During the bridge type study in 1995, four methods were considered for bringing span units to erection points behind Bodie Island: a dredged barge canal, a temporary access (haul) road, a work bridge, and top-down construction. The characteristics and feasibility of each method are described below. That study found that use of top-down construction is not practical, and a work bridge would be practical only in some situations. The four practical methods assessed in 1995 are described as follows:

Dredged Barge Channel. A dredged channel is planned for the portion of the main span behind Bodie Island and in the inlet only where the water depth is less than 6 feet (1.8 meters). This approach was used for construction of Bonner Bridge, as well as for emergency repair when spans were lost on October 26, 1990.

The channel would be about 120 feet wide (36.6 meters) and placed approximately 30 feet (91 meters) west of the proposed structure. The channel likely would require continuous dredging because of shifting sands and currents; this phenomenon was experienced by the contractor who

built Bonner Bridge in 1962. The channel would be marked by the Coast Guard. Once all the construction for the north approach and the far span of the main bridge has been completed, the contractor would move to the next main bridge span and the preceding portion of the channel would be allowed to fill in naturally. Dredging spoil would be pumped or transported by barge to an in-water disposal site near the project area. If the spoil exhibits the necessary properties, it could be used for beach nourishment or disposal. The appropriate location for spoil disposal would be determined based on coastal conditions at the time of construction. The required USACE permit would be obtained, per Section 103 of the Marine Protection Research and Sanctuaries Act. NCDOT would work with the USACE, the USFWS, the NMFS, and the NCDENR to develop a dredging technique and disposal plan that would minimize harm to natural resources. If requested by appropriate agencies, attempts would be made to reduce dredging activities as much as possible during the spring to avoid minor effects to the fisheries resources.

Haul Road. A haul road is expected for construction of the north approach. During discussions with contractors, it was indicated that temporary haul road construction, instead of a dredged channel, might be preferred for the construction of approach spans. This interest was based on the possibility that a haul road might prove more economical because less maintenance might be required. Such a road would be 65 feet (19.8 meters) wide with 40-foot (12.2 meter) wide "fingers" perpendicular to the 65-foot (19.8 meter) main road at each foundation. It would be placed on the west side of the new bridge near the outside edge of the foundations. The haul road could be composed of fill obtained from the inlet or sound. The fill would be placed on a geotextile fabric. The fabric also would be on the slopes of the fill to minimize erosion. A top surface (if required) could be brought in from a mainland location. Dikes could be placed along the edge of the fill's upper surface or around equipment to prevent liquid materials associated with construction from spilling into the adjoining waters and wetlands. At the end of construction, the top surface of the fill would be removed and disposed of in accordance with NCDOT requirements, and the remaining fill would be disposed of in the inlet or sound. The fabric would be removed and the area it covered revegetated. The appropriate location for obtaining and disposing of the fill material would be determined based on coastal conditions at the time of construction. The required USACE permit would be obtained.

Under a haul road construction scenario, bridge components could be shipped and transported by truck to where they would be lifted into place by a crane. Some maintenance of the haul road would be required because of tidal action or storms.

The potential for compaction (the compression of the existing ground) exists with a haul road construction scenario. In this case, however, the likelihood of there being a substantial area of organic material under the haul road is remote. There is only a thin layer of organic material covering sand, which is not compactable. Therefore, the possibility of compaction would be minimized.

Work Bridge. A work bridge must support a live load, such as cranes and trucks, greater than that for the proposed permanent structure. It would have to be used by vehicles carrying piles and segments weighing up to 100 tons (90.7 metric tons) and equipment capable of hauling and placing the components. A work bridge could be one of two types:

1. A temporary short span, low elevation structure built adjacent to the new bridge site. Assembly of this type of work bridge would begin at the abutment and be built span-by-span using the top-down approach. In top-down construction, the last span built is used by construction equipment to place the piers, girders and decking for the next span. Disturbance to the ground below would be caused by pile driving operations at pier locations, ongoing construction operations, and equipment maintenance.

2. A bridge founded on a row of anchored barges, spaced closely together. Where the water is shallow, the barges would have to be dragged into position and dredging may be required to keep the barges floating and to remove them. The potential for loss of the work bridge during a storm would be greater with this type of foundation than the temporary short span, low elevation structure described above.

A work bridge would not be practicable for replacing the dredged canals expected in some locations for construction of the main bridge. The concrete piles used in the main bridge's foundation would be too large to be lifted by a conventional crawler crane.

A work bridge would not be practicable for completely replacing the haul road planned for construction of the north approach for several reasons. A work bridge could be more expensive. In addition, the risks of materials falling into the surrounding waters would be greater with the work bridge than the haul road. Scour likely would occur around the numerous bents (25-foot [7.6-meter] spans) that would make up the work bridge's foundation. A work bridge instead of a haul road for short distances at critical locations, such as SAV locations, could be used and in the case of SAVs, is assumed in the impact assessment in Chapter 4.

Top-Down Construction. Construction equipment is situated near the last span built and is used to place the piles, piers, and superstructure components for the next span. Span lengths, pile sizes, and weights are limited by the capacity and reach of construction equipment and the capacity of the permanent or temporary structure to carry the construction loads. The penalties usually associated with this type of construction are additional costs, additional construction time, shorter approach spans, and an increased number of piers. Very strict tolerances are required for pile locations for top-down construction. Thus, pile driving requires more construction equipment, a longer construction time, and increased cost. The construction duration is longer than that of other methods because the construction of each span must be completed before construction of the succeeding span can begin.

Top-down construction would not practicable for the replacement of the bridge over Oregon Inlet because bridge span lengths would have to be substantially reduced. Reducing the span length would increase project costs.

Construction of Temporary Construction Fills and Permanent Approach Road Fills

Except for the top surface, temporary haul road and permanent approach road fills would consist of fill dredged from the inlet or sound. A portion could come from the dredged channels used in construction. The top surface (e.g., clay or gravel), if required, could be obtained from:

- A mainland location. For the replacement of the bridge over Roanoke Sound/Muddy Channel, the NCDOT obtained fill from the Manns Harbor area, the nearest mainland location to Oregon Inlet.

- Material excavated during the creation of new wetlands under a wetland replacement program.

- An upland location on Hatteras or Bodie islands. Material from Bonner Bridge's approach embankment would be used to replace the material borrowed and restore the borrow site. Existing approach road embankment material also could be used to replace material borrowed from a mainland location.

As an alternative to using dredged material for all but the top surface, the entire approach fill could be obtained from one or more of the three sources listed above.

Staging Area(s)

Land area for construction staging would be desirable near the project. A staging area(s) near the construction project would make it easier to manage the construction process, make it easier to respond to emergencies, be less costly, and reduce construction-related traffic on NC 12. Both water and road access would be desirable. Mostly upland site(s) would be selected.

A staging area would be used for one or more of the following:

- Receipt of concrete and other construction materials by truck;
- Loading various components onto construction barges;
- Receiving major approach span components;
- Construction management and worker trailers;
- Storage of construction equipment not in use; and
- Minor maintenance of construction equipment.

The most likely location available for staging on Hatteras Island would be the access road to the (former) Oregon Inlet Coast Guard Station. The Coast Guard Station site, itself also could be used because it is owned by the State of North Carolina. It is, however, a NRHP-listed site and the station building would need to be relocated within the context of the project's Memorandum of Agreement with the State Historic Preservation Office before it could be used as a staging area. Use of land from the Pea Island National Wildlife Refuge would have to be found by the USFWS to be compatible with Refuge's mission. With the Preferred Alternative, NCDOT does not plan to request the use of Refuge lands for construction staging. Construction associated with the Preferred Alternative would remain within the NC 12 easement and other state-owned land as the project passes through the Refuge. A staging area on Bodie Island would need to be approved by the NPS prior to commencement of construction. Coordination with NPS and obtaining necessary permits would be the responsibility of the construction contractor (including any mitigation measures stipulated). Any approved staging areas permitted by the NPS would be indicated on construction sequencing plans and submitted to the NCDOT and permitting agencies for review and comment.

Following completion of the Oregon Inlet bridge in the Parallel Bridge Corridor, the staging area(s) would be restored to a condition similar to that prior to the start of construction. Specifics regarding staging operations would be developed during the project's design.

2.10.2 NC 12 Maintenance Alternative Characteristics

2.10.2.1 Nourishment

The Nourishment Alternative assumes that NC 12 would remain in its current location and beach nourishment plus dune enhancement would be used to maintain an adequate beach and dune system: 85 to 140 feet (25.9 to 42.7 meters) of beach and berm, 60 to 120 feet (18.3 to 36.6

meters) of dune base, and a 25-foot (7.6-meter) clearance to the edge of pavement. The new Oregon Inlet bridge would enter the Refuge within the easement of the Bonner Bridge terminus. Thus, a new NC 12 easement would not be needed with this alternative. The location of proposed nourishment areas and new dunes are shown in Figure 2-18.

The minimum beach nourishment project length along the beach would be 5,000 feet (1,524 meters) with 500-foot (152.4-meter) tapers (transition from nourished beach to beach that does not require nourishment) on each side. The total length of beach to require regular nourishment would be approximately 6.3 miles (10.1 kilometers). Nourishment would occur in four locations, as shown in Figure 2-18.

When the distance from the edge of NC 12's pavement to the active shoreline is less than or equal to the buffer width of 230 feet (70.1 meters) as described in Section 2.6.1.1, NC 12 would be vulnerable to short-term storm impacts. This potential factor would be mitigated by the presence of dunes. Dunes would protect the highway by providing a physical barrier between the ocean and the highway during storm events that cause flooding and sand inundation from ocean overwash. In the southern part of the Refuge, dunes 20 feet (6.1 meters) above grade with 1:3 side slopes and a 25-foot (7.6-meter) offset from the edge of pavement would be built and maintained. Building a dune of this size on a 230-foot (70.1-meter) footprint would leave a beach width of 85 feet (25.9 meters). Two such dunes would be built in locations shown in Figure 2-18.

In the ponds area and north of the ponds, a dune 10 feet (3.0 meters) above grade with 1:3 side slopes and a 25-foot (7.6-meter) offset from the edge of pavement would be built and maintained. On a 230-foot (70.1-meter) footprint, this would leave a beach width of 145 feet (44.2 meters). Four such dunes would be built in locations shown in Figure 2-18. The dunes would be sized so no more than 50 percent of each dune's volume would be lost over 12 years. The dunes would be restored to their original size every 12 years. The difference in the size of the dune required for the same level of protection in different locations is related to the variance in the offshore slope of the ocean bottom at the different locations. In the northern Rodanthe area, the offshore slope is steeper than elsewhere in the project area, which causes increased wave run-up during storms, thereby resulting in increased erosion and necessitating a larger dune in order to maintain 50 percent of the dune's volume over 12 years.

Sand requirements for nourishment and dunes would vary by location, with the greatest requirements for sand (61 percent) occurring at the southern end of the Refuge. Sand requirements through 2060 in cubic yards (cubic meters) would be:

	South End of Refuge	*Refuge Ponds Area*	*North of Refuge Ponds*	*Total*
Dunes	866,700 (662,640)	144,400 (110,402)	22,200 (16,973)	1,033,300 (790,015)
Nourishment	27,550,000 (21,063,490)	12,200,000 (9,327,569)	5,850,000 (4,472,646)	45,600,000 (3,486,370)
TOTAL	28,416,700 (21,726,130)	12,344,400 (9,437,971)	5,872,200 (4,489,619)	46,633,300 (35,653,720)

Approximately 61 percent of the cost of nourishment and associated dunes (see Section 2.12) would occur near the southern end of the Refuge.

Nourishment areas would be renourished every four years. The nourishment program assumes that no part of NC 12 is ever less than 230 feet (70.1 meters) from the active shoreline. The four-year cycle could be repeated by either a single renourishment program every four years or annual nourishment programs affecting a quarter of the area to be nourished.

In July and August 1994, the NCDOT, acting through the auspices of the OBTF (the interagency group charged with developing short-term and long-term solutions to threats to NC 12 from beach erosion on Hatteras and Ocracoke islands), conducted preliminary sand searches offshore of Hatteras and Ocracoke islands using a combination of seismic profiling (a sea floor mapping technique) and vibracores (a technique for obtaining sediment samples). The results of the sand search for northern Hatteras Island were reported by Boss and Hoffman (2000). Based on these preliminary results, two potential borrow areas (PBAs) were identified, one off the north end of Hatteras Island near Oregon Inlet approximately 2.2 miles (3.5 kilometers) seaward (PBA-A), and the other approximately 1.7 miles (2.7 kilometers) seaward of Rodanthe (PBA-B). The preliminary assessment of the amount of material available from these two PBAs is 69.0 million cubic yards (52.8 million cubic meters) for PBA-A and 56.0 million cubic yards (42.8 million cubic meters) for PBA-B. A detailed assessment of the compatibility of the borrow material with the native beach material has not been accomplished; however, the grain size analysis performed on sediment samples collected from the vibracores appeared to indicate that the material would be suitable for nourishment as well as minimizing the environmental impacts to the beach associated with nourishment. Accordingly, cost estimates for the nourishment alternatives were made based on the assumption that there would be enough suitable material in the two PBAs to support beach nourishment over the next 50 years. In the absence of a detailed compatibility analysis, an overfill factor of 1.2 was assumed for the offshore borrow material (i.e., in order to obtain 1 cubic yard [0.8 cubic meter] of compatible beach fill material in place along the beach, 1.2 cubic yards [0.9 cubic meter] of material would have to be removed from the borrow areas). NCDOT has contracted with the NC Geological Survey to analyze additional sand source information from US Geological Survey sources.

Another borrow source could be the USACE's annual Oregon Inlet ocean bar channel maintenance program. Sand dredged annually from the ocean bar could be adequate for most of the sand needed for nourishment in the northern part of the Refuge (at the ponds and north of the ponds). The channel across the ocean bar is authorized to a depth of 14 feet (4.3 meters) below mean low water (MLW) over a width of 400 feet (121.9 meters). To obtain all of the material needed for the northern part of the Refuge, a channel depth of 18 feet (5.5 meters) would be needed. Material for nourishment at the southern end of the Refuge would still be obtained from offshore borrow areas.

Access to the existing parking lot immediately south of Oregon Inlet would be provided by a driveway that would combine the existing road in the area leading to the (former) Oregon Inlet US Coast Guard Station with a new connection immediately south of the station between that road and the parking lot.

2.10.2.2 Road North/Bridge South

With this alternative, NC 12 would be placed on a bridge west of Hatteras Island beginning at a new intersection created at the driveway that leads to the temporary ferry terminal in Rodanthe and continuing to a point approximately 2 miles (3.2 kilometers) north of the Refuge's southern boundary where the project would meet existing NC 12. This part of the island is expected to remain stable with respect to NC 12 through the year 2060; therefore, the alignment of NC 12 would remain unchanged for 2.6 miles (4.2 kilometers). Beginning at a point approximately 1.3

miles (2.1 kilometers) south of the Refuge's ponds NC 12 would be relocated to a point 230 feet (70.1 meters) west of the forecast 2060 high erosion shoreline. This relocation would continue 7 miles (11.4 kilometers) north until the relocated NC 12 would meet the Oregon Inlet bridge. The location of improvements is illustrated in Figure 2-19.

The existing dunes along the oceanside of NC 12 would not be re-built (i.e., they would be allowed to erode naturally). Not re-building the dunes would support Refuge and Seashore policies to let natural processes take their course. However, three 10-foot-high dunes, totaling 2,100 feet (640 meters) in length would be built east of and near the new road in the future as conditions warrant. They would be built as the shoreline erodes towards the relocated road and approaches a distance of 230 feet (70.1 meters) from the pavement. The first one is expected to be built by 2030.

Access to the existing parking lot immediately south of Oregon Inlet would be provided in the same manner as the Nourishment Alternative.

As with the bridge in the Pamlico Sound Bridge Corridor (described in Section 2.9.2), the typical section of the bridge in the Rodanthe area would provide two 12-foot (3.6-meter) travel lanes and two 8-foot (2.4-meter) shoulders. This bridge's typical section is illustrated in Figure 2-13. The NCDOT anticipates that the typical bridge span would be 100 feet (30.5 meters). For the bridge superstructure (spans between piers), the use of girders is likely expected. For the bridge substructure (foundation and support for the superstructure), precast piles are planned.

As with the approach roads of the bridge in the Pamlico Sound Bridge Corridor (described in Section 2.9.3), the relocated roadways' typical sections would have two 12-foot (3.6-meter) travel lanes with 8-foot (2.4-meter) shoulders (4-foot/1.2-meter paved) (see Figure 2-14). The roadway would be built within a 100-foot (30.5-meter) right-of-way. The elevation of the roadway would be similar to the elevation of existing NC 12, generally 2 to 5 feet (0.6 to 1.5 meters) above mean sea level. The final design of the bridge portion would account for wave energy, storm surge, scour, and corrosive environmental conditions in a manner similar to that described in Section 2.10.1.2 as applicable to the sound-side, Rodanthe area setting of this bridge.

A design speed (maximum safe speed that can be maintained under favorable driving conditions) of 60 miles per hour (96.6 kilometers per hour) would be used for both bridge and roadway. The posted speed would remain at 55 miles per hour (89 kilometers per hour).

As with the Intersection Rodanthe Terminus for the Pamlico Sound Bridge Corridor, a traffic signal would be provided at the intersection of the new bridge in the Rodanthe area with existing NC 12. All southbound bridge traffic would have to at least slow down to turn at the signalized intersection before leaving the bridge and entering the Rodanthe section of NC 12 with its slower speeds and numerous cross streets and driveways intersecting NC 12. This intersection would carry NC 12 traffic at a desirable level of service (LOS) during forecast peak season weekday traffic for 2025. The level of service would be:

- B on a 2025 peak season weekday;
- D on a 2025 peak season weekend; and
- E on a 2025 peak season Saturday.

The signalized intersection would include a single exclusive left-turn lane for northbound NC 12 traffic turning to reach the proposed bridge and a single exclusive right-turn lane for southbound bridge traffic turning to continue south on NC 12. LOS D on a peak season weekday meets the NCDOT's and the FHWA's LOS objectives for a location with a seasonal population and is the same LOS expected on the rest of NC 12 within the project area in 2025. Dual exclusive left turn lanes for northbound NC 12 traffic would improve conditions to LOS D for the 2025 peak season Saturday period. (See Section 1.5.7 for a definition of the LOS measures and additional discussion of LOS along NC 12.)

2.10.2.3 All Bridge

This alternative would include the same bridge in the Rodanthe area described in the previous section (see Section 2.10.2.2) for the Road North/Bridge South Alternative. Instead of relocating NC 12 as a roadway in the central and northern part of the Refuge, NC 12 would be relocated on a bridge. Two road segments would be included in this relocation, one near Oregon Inlet and one just north of the Refuge's ponds where access from NC 12 to the Refuge would be provided. Access to the Refuge also would be available in a 1.8-mile (2.9-kilometer) section of NC 12 that would be left unchanged between the Rodanthe area bridge and the beginning of the next bridge south of the ponds. The bridges associated with this alternative would span the five potential breach locations described in Section 2.6.2.3 and would be at least 230 feet (70.1 meters) west of the forecast 2060 high erosion shoreline. The location of improvements is illustrated in Figure 2-20.

The bridges in the central and northern part of the Refuge would begin approximately 1.7 miles (2.7 kilometers) south of the Refuge's ponds. A bridge would continue north for 5.2 miles (8.4 kilometers) to the northern dike of the northern-most pond where a 1,000-foot (305-meter) section of roadway would be placed. At this location, the Refuge could provide an access point to the beach and the hiking trails along the perimeter of the northernmost pond. NC 12 would then continue an additional 1.4 miles (2.3 kilometers) to a second 1,000-foot (305-meter) section of roadway. Here the relocated NC 12 would be connected to the existing roadway, which would be retained from this point north to the parking lot just south of Oregon Inlet. North of this second short roadway section, NC 12 would continue northward 0.4 mile (0.6 kilometer) on bridge to meet the Oregon Inlet bridge.

The existing dunes along the oceanside of NC 12 would not be re-built (i.e., they would be allowed to erode naturally). Not re-building the dunes would support Refuge and Seashore policies to let natural processes take their course.

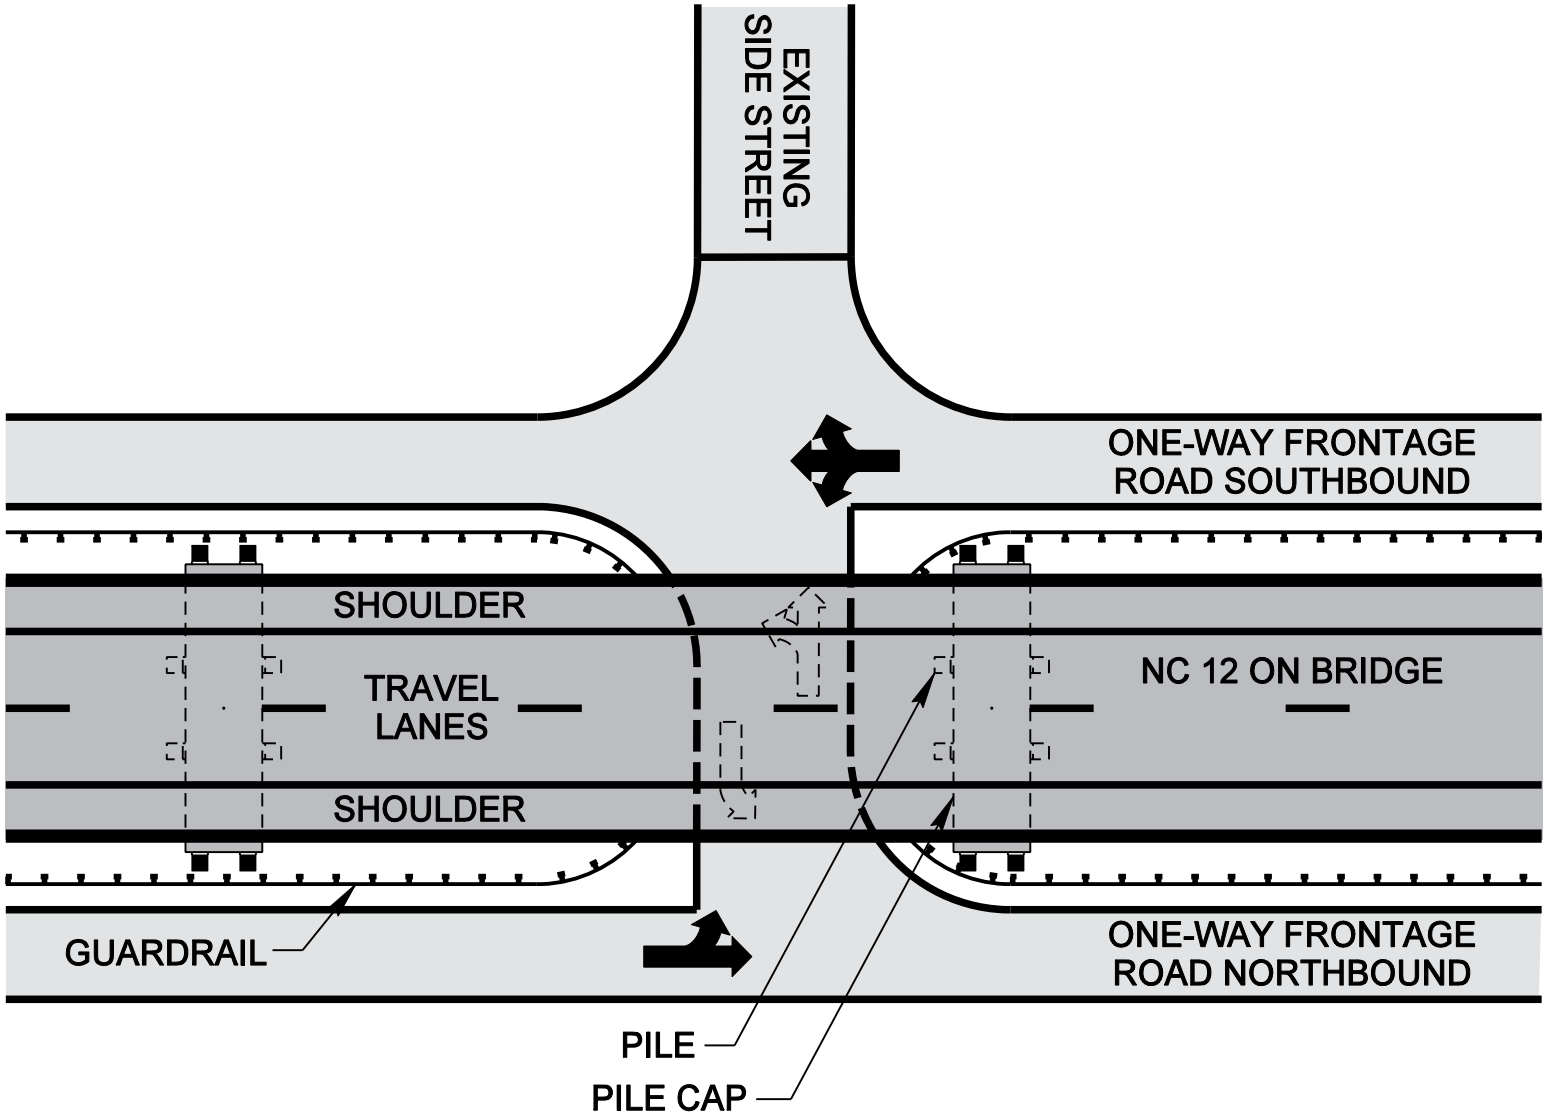
Road and bridge design characteristics, as well as traffic characteristics at the new Rodanthe intersection, would be identical to those described for the road and bridge components of the Road North/Bridge South Alternative described above. Final design of bridges would account for wave energy, storm surge, scour, and corrosive environmental conditions in a manner similar to that described in Section 2.10.1.2 as applicable to the on-shore and the sound-side, Rodanthe area setting of the bridges associated with this alternative.

2.10.2.4 Phased Approach

Two NC 12 maintenance alternatives are under consideration with the Phased Approach Alternative. They are identical until their southern end within Rodanthe. They are:

- Phased Approach/Rodanthe Bridge Alternative (Preferred); and
- Phased Approach/Rodanthe Nourishment Alternative.

Characteristics of Phased Approach/Rodanthe Bridge Alternative (Preferred)



This alternative proposes maintenance of NC 12 in the existing easement by building bridges as needed. The total constructed length of the Phased Approach/Rodanthe Bridge Alternative (Preferred) would be 14.0 miles (22.5 kilometers). It would begin in Rodanthe just to the north of Sudie Payne Road (see Figure 2-21), extend to the north through the Refuge and across Oregon Inlet, and end on the southern end of Bodie Island approximately 0.2 mile (0.3 kilometer) north of the Oregon Inlet Campground driveway. The total length of the alternative between the two termini is approximately 16.1 miles (25.9 kilometers), but the constructed length is only 14.0 miles (22.5 kilometers) because of a 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge that is not expected to be threatened by erosion prior to 2060. The bridge would extend a total of approximately 1.1 miles (1.8 kilometers) south of the Refuge boundary into Rodanthe. Access to properties adjacent to the bridge in Rodanthe would be provided by a one-lane, one-way frontage road on each side of the NC 12 bridge. The two frontage roads would flare out and connect with NC 12 at a four-legged intersection approximately 400 feet (121.9 meters) south of the end of the project. Crossovers to provide access between the two frontage roads underneath the NC 12 bridge were assumed to be provided in three locations: just south of the Refuge boundary; across from SR 1445 (Cross of Honor Way); and just north of America Drive. The frontage roads and a typical crossover are illustrated in Figure 2-23.

A small amount of new right-of-way would be required in Rodanthe along most of the length of the alternative to accommodate the two frontage roads in Rodanthe. In general, the right-of-way width would increase from 100 feet (30.5 meters) to 107 feet (32.6 meters). However, for approximately 600 feet (182.9 meters) near the southern end of the alternative (starting at approximately the entrance to the mobile home park shown on Figure 3-1 and continuing south), the existing right-of-way width is only 60 to 68 feet (18.3 to 20.7 meters), so it would increase from this width to 107 feet (32.6 meters). In addition, the right-of-way width would increase to a maximum width of approximately 147 feet (44.8 meters) for a short distance at the intersection of the two frontage roads and existing NC 12 at the southern end of the alternative. A temporary construction easement approximately 5 feet (1.5 meters) wide could be needed on both sides of NC 12 for most of the length of the alternative through Rodanthe. The right-of-way would not be widened and no construction easement purchased within the National Register-eligible Rodanthe Historic District (see Section 3.4.1).

Characteristics of Phased Approach/Rodanthe Nourishment Alternative

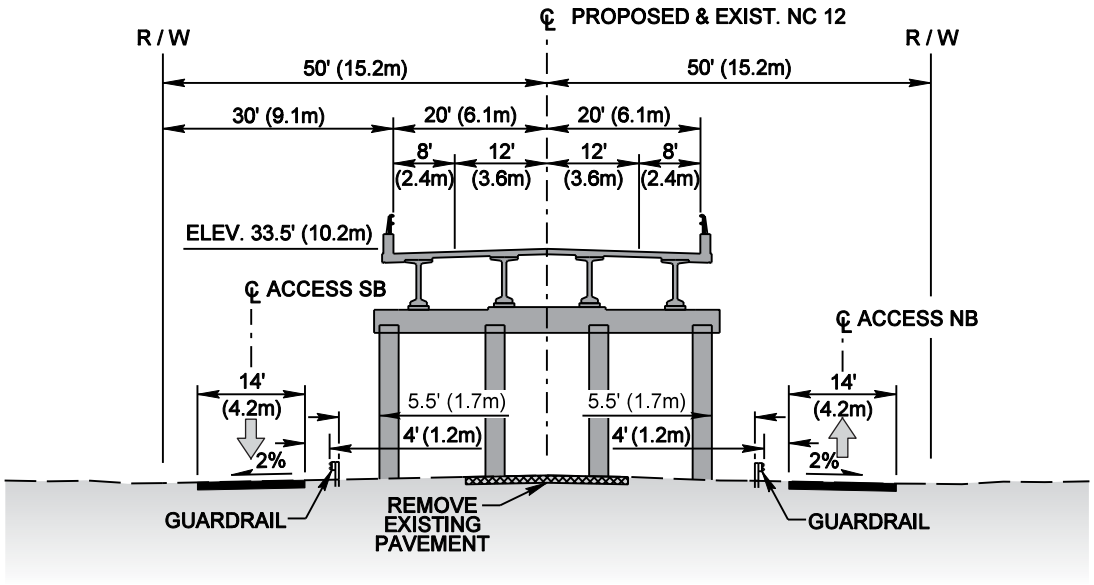
The Phased Approach/Rodanthe Nourishment Alternative would be similar to the Phased Approach/Rodanthe Bridge Alternative with one exception. The southern end of the alternative would only extend a total of approximately 0.3 mile (0.5 kilometer) south of the Refuge boundary into Rodanthe. Because it is substantially shorter than the Rodanthe Bridge Alternative, only one crossover between the one-way frontage roads would be provided immediately south of the Refuge boundary.

The same minor amount of additional right-of-way (i.e., approximately 7 feet [2.1 meters]) would be required along most of the length of this alternative in Rodanthe, with a maximum width of approximately 147 feet (44.8 meters) required for a short distance at the intersection of the frontage roads with existing NC 12. The approximately 5-foot-wide (1.5-meter-wide) temporary construction easement could be needed on both sides of NC 12 for most of the length of this alternative in Rodanthe.

PHASED APPROACH BRIDGE IN RODANTHE WITH FRONTAGE ROADS

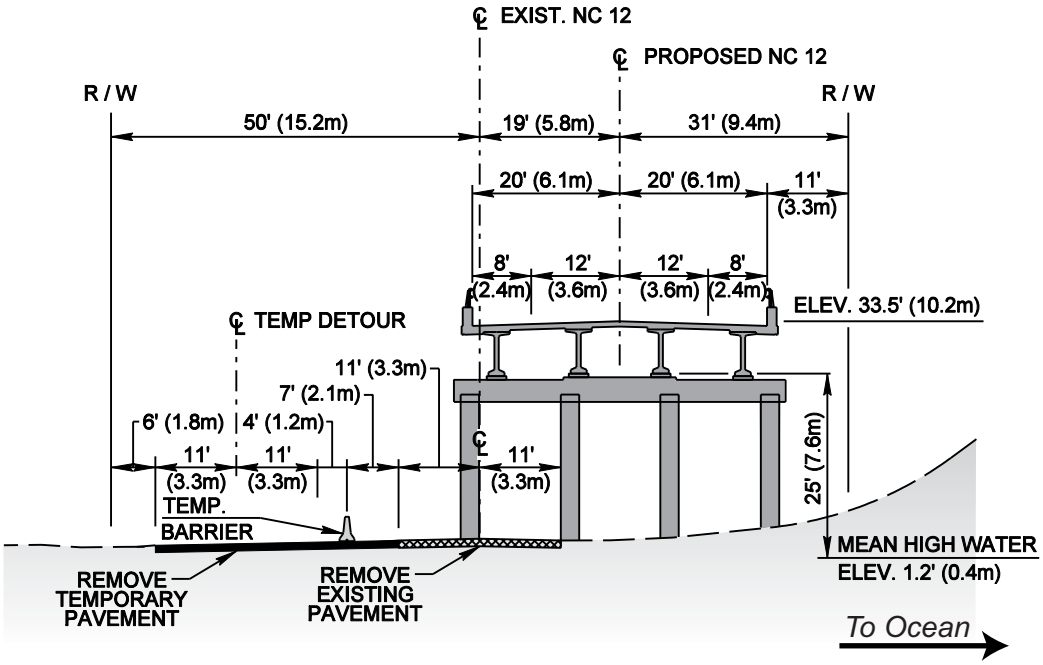
Figure 2-23

South of the bridge, NC 12 in Rodanthe would be protected through 2060 by beach nourishment. The total required beach nourishment length would be approximately 6,000 feet (1,829 meters), including 500-foot-long (152.4-meter-long) tapers on each end. Nourishment would extend approximately 1,500 feet (457 meters) into the Refuge including the taper of 500 feet (152.4 meters). As with the other alternatives involving beach nourishment, it was assumed that nourishment would be needed every four years. The estimated amount of sand needed for the Phased Approach/Rodanthe Nourishment Alternative is 2.3 million cubic yards (1.8 million cubic meters) for the first cycle of nourishment, and 1.5 million cubic yards (1.1 million cubic meters) every four years throughout the life of the project (through 2060).



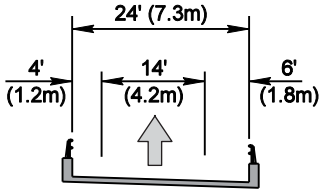
Design Features of Both Phased Approach Alternatives

The NC 12 maintenance bridges for the Phased Approach alternatives (including the Preferred Alternative) would have the same typical section as the bridges with the All Bridge Alternative, including two 12-foot (3.6-meter) lanes with 8-foot (2.4-meter) shoulders on each side, for a 40-foot (12-meter) roadway width (Figure 2-24). A design speed of 60 miles per hour (96.6 kilometers per hour) was used on the mainline NC 12 bridges.



Based on a recommendation related to structure clearance heights from the August 2006 Constructability Workshop (see Section 2.7), these bridges would have a minimum 25-foot (7.6-meter) vertical clearance above mean high water. This height assumes the flat storm surge elevation plus the wave height plus some additional clearance. However, the Constructability Workshop recommendation also stated that this height may be re-evaluated based on a determination of the desired level-of-service of the structure during storm events, and should be refined during final design. Based on coastal data from the OBTF science panel, the NC 12 bridges between the northern end of Hatteras Island and the southern end of the Canal Zone Hot Spot were assumed to have a more substantial foundation than the remainder of the NC 12 bridges to the south in order to accommodate a potential breach that could be deeper than breaches that might occur elsewhere in the Refuge. At the northern end of Hatteras Island, a foundation that includes eight 54-inch (137.2-centimeter) cylinder piles was assumed. Elsewhere, eight 30-inch (76.2-centimeter) piles were assumed. A concrete girder ("I" shape) superstructure was assumed, but segmental box girders also could be used as proposed for the Oregon Inlet bridge. The span lengths were assumed to be 120 feet (37 meters) for the full height bridges and 100 feet (30 meters) for the permanent and temporary approach bridges (i.e., transitions from full height bridges to fill as the bridges come down to the existing grade). These are considered reasonable foundation and span assumptions for the purpose of analysis in this FEIS, but could change in project design.

Like the Pamlico Sound Bridge Corridor alternatives and the Parallel Bridge Corridor with All Bridge Alternative, which also include long bridges, proposed bridge cost estimates assume that turn-outs are built on the bridge where a disabled vehicle can be moved out of the way of traffic. The maximum desirable distance between these turn-outs was assumed to be 3 miles (4.8 kilometers) and the turn-outs would be 300 feet (91.4 meters) long. During final design, the NCDOT also would consider implementation of the following ITS devices to provide motorists with advance notification as to travel conditions on NC 12: Highway Advisory Radio, Roadway Weather Information Systems, Variable Message Signs, and Closed Circuit Television cameras, as well as fiber optic cabling to link the technologies and incident management patrols.



All five potential breach locations in the study area would eventually be bridged by the Phased Approach/Rodanthe Bridge Alternative (Preferred). The Phased Approach/Rodanthe Nourishment Alternative would only partially bridge the southernmost potential breach location,

TYPICAL SECTION IN RODANTHE

SB = Southbound
NB = Northbound

PHASED APPROACH ALTERNATIVE TYPICAL SECTIONS

Figure 2-24

which is the one considered most likely to suffer a breach before 2060; however, this alternative assumes nourishment would forestall a breach in this area.

Because most of NC 12 ultimately would be on structure through the Refuge with the Phased Approach alternatives (including the Preferred Alternative), the existing dunes along the oceanside of NC 12 would not be re-built (i.e., they will be allowed to erode naturally). As with the other Parallel Bridge Corridor alternatives that do not involve dune construction and/or beach nourishment (i.e., the All Bridge Alternative and most of the Road North/Bridge South Alternative), not re-building the dunes would support Refuge and Seashore policies to let natural processes take their course.

The final design of the NC 12 maintenance bridges associated with the Phased Approach alternatives (including the Preferred Alternative) would account for wave energy, storm surge, scour, and corrosive environmental conditions in a manner similar to that described in Section 2.10.1.2 as applicable to the sound-side, Rodanthe area setting of this bridge.

Refuge Access

Four one-lane ramps would be built to provide vehicular access to and from the parking lot currently used to access the fishing catwalks on the existing Bonner Bridge, accommodating all directions of travel (see Figure 2-22). The ramps would have 12-foot (3.6-meter) lanes and a 6-foot (1.8-meter) shoulder. The Phased Approach alternatives (including the Preferred Alternative) would have a second point of access into the Refuge, within the 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge that would not be threatened by erosion prior to 2060.

Construction within the Existing Easement of Pea Island National Wildlife Refuge

The NCDOT's existing easement through the Pea Island National Wildlife Refuge is 100 feet (30.5 meters) wide and is centered on existing NC 12. The proposed structures and all construction activities, such as material/equipment deliveries, excavations, temporary shoring, pile driving, and erection of bridge girders, would remain inside the existing easement. All foundation elements, such as footings, piles, and drilled shafts, also would remain within the easement limits.

The design-build contractor would be required to submit a construction staging plan which would include plans, sections, and written descriptions to the NCDOT and the permitting agencies for review that shows the intended sequencing, erection schemes, and means of site access. This plan also would depict positions of traffic lanes, which would be maintained through the construction zones.

2.10.2.5 Construction Timing and Phasing of NC 12 Maintenance Components

With the exception of the Phased Approach alternatives (including the Preferred Alternative), it was assumed that construction of the NC 12 maintenance component of the Parallel Bridge Corridor would likely occur in parallel with the Oregon Inlet bridge. For the Phased Approach Alternatives (including the Preferred Alternative), it was assumed that the NC 12 maintenance components would be phased, with construction beginning after the completion of the Oregon Inlet bridge and timed as discussed below under "Phasing Timing and Minimizing Impacts of NC 12 Maintenance" and in commitment number 15 in the Project Commitments section of this FEIS. The following paragraphs describe the assumed phasing for the Phased Approach alternatives (including the Preferred Alternative) and opportunities for phasing the other NC 12 maintenance components of the Parallel Bridge Corridor alternatives.

Construction Phasing for the Phased Approach Alternatives

The Phased Approach alternatives (including the Preferred Alternative) are likely to be built in four phases based on the following criteria: the condition of Bonner Bridge, the location of forecast beach erosion, and potential breach locations (see Figure 2-21). The Oregon Inlet bridge replacement is the most urgent need and is Phase I. Phase II would bridge three locations where NC 12 is most threatened by shoreline erosion, as well as four of five potential breach locations. Phase III would bridge the fifth breach location and the next area threatened by shoreline erosion. Phase IV would bridge the final two areas where NC 12 would be threatened by shoreline erosion. The phasing schedule would change if the future shoreline evolves differently from that currently forecast based on the programs described in the next section. The phases are shown in Figure 2-21 and described below:

1. Phase I (2009 to 2015 TIP). The Phase I project would consist of the construction of a new Oregon Inlet bridge. The southern end of the Oregon Inlet bridge on Hatteras Island would not be brought down to grade, but would end at full height for future extension to the south (i.e., at an elevation of approximately 33.5 feet [10.2 meters] above mean sea level assumed for purposes of the impact assessment as shown in Figure 2-24). Access to the northern end of Hatteras Island is assumed to be provided by ramps from the bridge that would reach the ground near the entrance to the parking lot that currently serves the catwalks on Bonner Bridge. The beach nourishment component of the Phased Approach/Rodanthe Nourishment Alternative also could begin in Phase I, replacing storm-related NC 12 maintenance activities that would otherwise occur until Phase II is implemented. Nourishment would then be repeated at four-year intervals.

2. Phase II (Post 2015). The Phase II project would consist of constructing three separate bridges within the easement of existing NC 12 in locations where there is either a likelihood of a future breach in Hatteras Island or the distance from the edge of NC 12's pavement to the active shoreline is predicted to be less than or equal to the buffer width of 230 feet (70.1 meters) by 2015.

   The southernmost bridge in Phase II would begin in the Refuge near the northern end of the Rodanthe 'S' Curves Hot Spot (see Figure 2-21) and extend into Rodanthe. As described above, two possible design options were developed for the southern end of this Phase II bridge in Rodanthe and are shown on Figure 2-21. With both design options, access to properties adjacent to the NC 12 bridge in Rodanthe would be provided by one-lane, one-way frontage roads on both sides of the bridge (see Figure 2-23). The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would be approximately 2.3 miles (3.7 kilometers) long and would extend approximately 0.8 mile (1.3 kilometers) into Rodanthe to a point that is 230 feet (70.1 meters) south and west of where the projected 2060 high erosion shoreline crosses NC 12. A 1,200-foot (366-meter) long permanent approach roadway (i.e., a permanent transitional bridge structure and retaining wall section that brings the bridge back down to grade) would be added to both ends of this bridge. This alternative would extend a total distance of approximately 1.1 miles (1.8 kilometers) south of the Refuge boundary into Rodanthe.

   The Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative would be approximately 1.5 miles (2.4 kilometers) long, with the proposed NC 12 bridge ending just south of the Refuge boundary. The 1,200-foot (366-meter) long permanent roadway approach at the southern end of the bridge would extend approximately 0.3 mile (0.5 kilometer) into northern Rodanthe. A 1,200-foot (366-meter) long permanent approach roadway also would be added to the north end of the bridge in the Refuge. The beach

nourishment component would begin in Phase I as noted above. This alternative would extend a total distance of approximately 0.3 mile (0.5 kilometer) south of the Refuge boundary into Rodanthe.

For both the Phased Approach alternatives (including the Preferred Alternative), the middle bridge in Phase II would be approximately 0.7 mile (1.1 kilometers) long. It would be adjacent to the southern half of the Refuge's North Pond, with the southern end being approximately at the northern end of the Sandbag Area Hot Spot. A 1,100-foot (335-meter) long temporary approach roadway (i.e., a temporary transitional bridge structure and retaining wall section that brings the bridge back down to grade) would be added to both ends of this bridge until the Phase IV bridges to the south and north are constructed.

The northernmost bridge in Phase II (for both the Phased Approach alternatives [including the Preferred Alternative]) would be approximately 2.6 miles (4.2 kilometers) long. It would tie into the southern end of the Oregon Inlet bridge constructed in Phase I, continue south through the Canal Zone Hot Spot (see Figure 2-21), and end near the northern end of North Pond. The second two access ramps for the north end of Hatteras Island also would be built as a part of this project. These ramps would combine with the ramps constructed in Phase I from the Oregon Inlet bridge to create a complete interchange for access to the northern end of Hatteras Island. The 1,100-foot (335-meter) long temporary approach roadway discussed above would be added to the southern end of this bridge until the Phase IV bridge to the south is constructed.

3. Phase III (Post 2020). The Phase III project would consist of constructing one bridge within the easement of existing NC 12 through a location where there is a likelihood of a future breach, as well as partially through an area where the distance from the edge of NC 12's pavement to the active shoreline is predicted to be less than or equal to the buffer width of 230 feet (70.1 meters) by 2020.

   The Phase III bridge would be approximately 1.9 miles (3.1 kilometers) long. It would start near the southern end of South Pond, within the southern portion of the Sandbag Area Hot Spot, and continue to the south past the southern end of the possible future breach in Hatteras Island that is in this area (see Figure 2-21). A 1,100-foot (335-meter) long temporary approach roadway would be added to the northern end of this bridge until the Phase IV bridge to the north is constructed. In addition, a 1,200-foot (366-meter) long permanent approach roadway would be added to the south end of the bridge.

4. Phase IV (Post 2030). The Phase IV project would consist of constructing two separate bridges within the easement of existing NC 12 in locations where the distance from the edge of NC 12's pavement to the active shoreline is predicted to be less than or equal to the buffer width of 230 feet (70.1 meters) by 2030 (see Figure 2-21).

   The southern Phase IV bridge would be approximately 1.6 miles (2.6 kilometers) long. It would be adjacent to New Field and South ponds (see Figure 3-1b) in an area through most of the Sandbag Area Hot Spot. This bridge would connect the middle Phase II bridge and the Phase III bridge. Because this bridge would connect to two previously constructed bridges, the temporary approach roadways previously built at the ends of the bridges would be removed while traffic is maintained on a temporary ramp placed to the west of the Phase II and III bridges.

The northern Phase IV bridge would be approximately 1.0 mile (1.6 kilometers) long. It would be adjacent to the northern half of North Pond (see Figure 3-1b) and would connect the two northern Phase II bridges. Once again, because this bridge would connect to two previously constructed bridges, the temporary approach roadways previously built at the ends of the two Phase II bridges would be removed while traffic is maintained on a temporary ramp placed to the west of the Phase II bridges.

With the completion of Phase IV, the resultant bridges would be over four to five miles in length. Therefore, a widened bridge section was included on both Phase IV bridges where a disabled vehicle can be moved out of the way of traffic. The maximum desirable distance between these turn-outs was assumed to be 3 miles (4.8 kilometers). In order to keep the turn-outs on the eastern side of the NC 12 bridges within the existing easement, a slight shift in the alignment of the bridges at the turn-outs would be required.

The construction duration for each of Phases II to IV is estimated to last approximately three years from letting. Phase I is estimated to last 3.5 years.

Phasing Timing and Minimizing Impacts of NC 12 Maintenance

NCDOT recognizes that shoreline erosion could occur at a more rapid or less rapid rate than assumed in the above phasing assumptions. A Hatteras Island breach could occur in the project area prior to the implementation of bridges to cross the project area's potential breach locations. It also is recognized that high levels of NC 12 storm-related maintenance are occurring at the three hot spots in the Refuge and that minimizing future storm-related maintenance along NC 12 is highly desirable. Finally, the Refuge has concluded that if the Phased Approach/Rodanthe Bridge Alternative (Preferred) is selected for implementation in a Record of Decision, any future storm-related maintenance outside the NC 12 easement will likely not be found compatible with the Refuge under the requirements of National Wildlife Refuge System Improvement Act of 1997.

The technical report *Bonner Bridge Replacement – Parallel Bridge Corridor with NC 12 Maintenance – Shoreline Change and Stabilization Analysis* (Overton and Fisher, June 2005) documents the results of the shoreline change and stabilization analysis that was conducted for the project area. For planning purposes, NCDOT considered the 2060 high erosion shoreline (described in Section 3.6.1.1) to be a reasonable assumption for current planning purposes. However, with recently published research on global climate change and its effects, additional analysis was conducted to identify, if any, gaps in methodology exist between the shoreline change and stabilization analysis when compared to recent and relevant research on climate change. Following a review of the additional analysis, it was determined that global climate change impacts have been reasonably accounted for in the existing shoreline change study. It was further concluded that too many unknowns exist to reasonably predict storm frequency and severity impacts to the project area.

With these factors in mind, after the issuance of the Record of Decision for this project, NCDOT will confine future NC 12 maintenance to the existing NC 12 easement. Further, it is NCDOT's intent to place a high priority on the implementation of Phase II. This intent recognizes the need to build Phase II, particularly in the 'S' Curves, Sandbag Area, and Canal Zone hot spots, as soon as it is practicable. The impact assessment presented in Section 4.6.8.6 of this FEIS assumes that construction of Phase II would begin upon the completion of Phase I.

In addition, the completion of Phases II and III would address possible, but less certain and less predictable, changes in sound-side erosion at Oregon Inlet (Section 3.6.3.2) and potential island

breaching (Section 3.6.3.4) by providing deeper and larger bridge foundations at the portion of Phase II near Oregon Inlet and by bridging the five potential breach locations in the project area. NCDOT also recognizes that decisions related to the implementation of Phases III and IV and the specific locations of Phases III and IV will likely evolve with actual geomorphological change relative to the NC 12 easement, whether from changes in the characteristics of expected beach erosion, the possible changes of sound-side erosion at Oregon Inlet, accelerated sea level rise (Section 3.6.3.3), or island breaching. The need to confine NC 12 maintenance work to the existing easement in the Phase III and IV areas, as well as in the 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge also must be taken into account in planning for Phases III and IV. Limiting the growth of NC 12 storm-related maintenance in the Phase III and IV areas to the extent practicable given the availability of transportation funding and the efficient use of those funds also is considered desirable. "Availability of funds" recognizes that future funding analyses indicate that funding availability will continue to limit how much can be built at one time and the need for phasing. "Efficient" recognizes that it is desirable from the perspective of cost to build the project in a few longer phases rather than numerous short phases.

NCDOT recognizes that any decision to proceed with the implementation of project phases need to occur before higher levels of NC 12 storm-related maintenance manifest themselves (defined in Section 4.6.8.6) because the process of planning, assessment, and construction of Phases III and IV could take approximately five years for each phase.

NCDOT intends to: 1) implement an island monitoring program in the project area on Hatteras Island and 2) to conduct breach response-related data gathering. The descriptions below provide a conceptual framework for these two commitments. NCDOT would develop and finalize the details of these two commitments within the context of Phase I implementation following the release of a Record of Decision.

The particulars of the monitoring program on Hatteras Island in the project area would be developed in consultation with representatives of the Refuge. This program would include the development of decision-making criteria for translating monitoring findings into a decision to move forward with Phases III and IV. Components of a monitoring program could include:

- Gather data (at appropriate time frames) related to:
  - Changing geomorphological characteristics (e.g., the width and elevation of the island, dune height, shoreline position, and nearshore bathymetry);
  - Relative distance from NC 12 to critical geomorphological features (e.g., shoreline, dune, estuarine shoreline); and
  - Storm events and associated NC 12 maintenance activities.

  Efforts would be made to merge these data with that of other geologic and biological datasets from other ongoing studies by others.

- On an annual (or post-storm) basis, identify from these data geomorphological trends relevant to a decision to move forward with Phases III and IV or refine their location.

- Consider in its evaluation of geomorphological trends known warning signs. These warning signs will serve as indicators of areas deserving of extra scrutiny during the annual consideration of

monitoring program findings and what they mean in terms of the timing and location of Phase III and IV implementation. Based on past experience, warning signs could include:

- A distance between the shoreline and the road of less than 650 feet (198 meters) (650 feet is based on measurements of the landward extent of washover fans that developed during Hurricane Isabel and should generally allow natural shoreline processes to occur without notable effects on NC 12 operations);

- Areas with weak dunes (e.g., low dunes that lack vegetation) that potentially require higher levels of storm-related NC 12 maintenance activity, proximity of the dune to NC 12, and the rate dunes may be advancing towards NC 12 (this recognizes that the frequency of dune maintenance is highest when a dune is less than 25 feet [7.6 meters] from the road);

- Increases in erosion rates over past trends; and

- Increases in NC 12 storm-related maintenance frequency or activity over previous years.

- Determine the shoreline and dune conditions under which the need for storm-related maintenance tends to escalate.

- Present annual monitoring findings and NCDOT conclusions on their relation to Phase III and IV planning, programming, and implementation to the Refuge for discussion. The conclusions may be refined based on Refuge input.

NCDOT recognizes there are several areas in the project area that are more susceptible to a breach because of the underlying geology and geomorphological characteristics of the barrier island and that the FEIS (Section 3.6.3.4) indicates that the southern part of the Refuge is the location most likely to suffer a breach prior to 2060. Further, a storm event of the nature required to create a breach in the southern part of the Refuge would probably occur once between now and 2060. The southern part of the Refuge is the location of a prior inlet, the island is very narrow with relatively small dunes, and there is a relic channel across the estuarine marsh. This potential breach location would be bridged in Phase II. But recognizing the possibility that a breach could occur in this location prior to the completion of Phase II, and that four other locations exist in the project area that are geologically susceptible to a breach (three are bridged in Phase II and one in Phase III), NCDOT would conduct a breach response-related data gathering program focusing on the southern end of the Refuge. Such a program could include: exploring further where sand of acceptable characteristics and volumes exists for use in closing a breach; options available for bridging a breach, their past use, their merits, and the situations for which they would be applicable; and other information that would facilitate timely (in order to reduce economic loss), environmentally sensitive, and cost-effective decision-making should a breach occur.

Opportunities for Phasing the Road North/Bridge South and All Bridge Alternatives

The discussion and assessment of the Road North/Bridge South and All Bridge alternatives presented in this FEIS assume that the entire project is built in a single construction program. As indicated in Section 2.10.2.1, the Nourishment Alternative is assumed to occur at four-year intervals and dune restoration at 12-year intervals. It would be possible, however, to phase construction of the Road North/Bridge South and All Bridge alternatives in a manner similar to the Phased Approach alternatives (including the Preferred Alternative). The assumed use of new easement or right-of-way for much of the length of these two alternatives does affect phasing opportunities. The endpoints of Phases I and II described below would need to make connections into the existing

NC 12 easement. These alternatives as defined in this FEIS do not cross the existing NC 12 easement at phasing endpoints. Phasing opportunities could be created as follows:

1. Phase I (2009 to 2015 TIP). The Oregon Inlet bridge could be built as a first phase of either the Road North/Bridge South, or All Bridge, alternatives if three conditions are met:

   a. The new bridge ties into the existing NC 12 easement in a manner similar to the Nourishment Alternative; and

   b. The alignment of the Phase II bridge or road south of the Oregon Inlet bridge is adjusted to connect to the changed southern bridge terminus.

2. Phase II (Post 2015). Phase II would consist of:

   a. The bridge in the Rodanthe area;

   b. A section of bridge or road approximately 0.7 mile (1.1 kilometers) long adjacent to the southern half of the Refuge's North Pond; and

   c. A section of road or bridge extending approximately 2.6 miles (4.2 kilometers) south of the southern terminus of the Oregon Inlet bridge.

   In order to accomplish the latter two components of Phase II (items "b" and "c"), two temporary roads would have to be built to connect the phase's endpoints into the existing NC 12 easement, one at the northern end of the section described under item "b" and one at the southern end of the section described under Phase II item "c." The northern end of the Phase II item "b" section, as currently assumed in this document, would be approximately 530 feet (161.5 meters) from the existing NC 12 easement with the Road North/Bridge South Alternative and approximately 570 feet (173.7 meters) from the existing NC 12 easement with the All Bridge Alternative. The southern end of the Phase II item "c" section, as currently assumed in this document, would be approximately 300 feet (91.4 meters) from the existing NC 12 easement with the Road North/Bridge South Alternative and approximately 370 feet (112.8 meters) from the existing NC 12 easement with the All Bridge Alternative. Finally, an adjustment would need to be made in the alignment of the All Bridge alternative at the southern end of the section described under Phase II item "b" above so it would connect into the existing NC 12 easement.

3. Phase III (Post 2020). This phase would involve building a road or bridge south of the Phase II section listed under Phase II item "b" above, with the southern starting point of the road being approximately 1.3 miles (2.1 kilometers) south of the Refuge's ponds and the southern starting point of the bridge being approximately 1.7 miles (2.7 kilometers) south of the Refuge's ponds. The starting points are defined for these alternatives in Sections 2.10.2.2 and 2.10.2.3, respectively.

4. Phase IV (Post 2030). This phase would complete the remaining two sections of the Road North/Bridge South and the All Bridge alternatives in the area of the Refuge's ponds.

2.10.2.6 Temporary Traffic Maintenance Roads with Phased Approach Alternatives

Temporary traffic maintenance roads would be needed to maintain traffic during construction of the Phased Approach alternatives (including the Preferred Alternative). These roads are assumed to have two 11-foot (3.4-meter) lanes with a 6-foot (1.8-meter) unpaved shoulder on the sound side of

the road. A barrier would likely separate travelers on the temporary roads from bridge construction. There would be an approximately 3-foot (0.9-meter) clearance between the travel lanes and the barrier. It was assumed that the new bridges within the Refuge would be built on the east side of the NC 12 easement, and the temporary roads would be on the west side of the NC 12 easement, away from the existing dunes. In Rodanthe, the new bridge would be in the center of the right-of-way, and construction access would be provided on the new one-way frontage roads (see Figure 2-23 and Figure 2-24). During construction of the Phase IV bridges, Phase II and III bridge approaches at four locations would be replaced adjacent to the bridge temporarily in order to maintain traffic while the Phase II and III bridges are extended in Phase IV. Two lanes of traffic are expected to be maintained in all locations throughout bridge construction.

2.10.2.7 Other Construction Assumptions

When working either over water where SAV is present or over wetlands, bridges associated with the Road North/Bridge South and All Bridge alternatives would be span-by-span using top-down construction. Most of the Refuge area over which the bridges would pass with these two alternatives is classified as wetland. Given the closeness of the Rodanthe area bridge associated with these two alternatives to the west side of Hatteras Island, it is expected that SAV is present along most, if not all, of the bridge length over water. The Phased Approach bridges would not be built in areas of SAV and would affect only wetlands within the NC 12 easement.

Once a project in the Parallel Bridge Corridor is complete, replaced sections of NC 12 would be removed within the Refuge.

2.11 Demolition and Removal of Bridges and Pavement

2.11.1 Demolition and Removal of Bonner Bridge

Upon completion of the proposed project, Bonner Bridge and its approach fills would be demolished and removed. Separate contracts would be issued for construction of the proposed bridge and demolition and removal of Bonner Bridge with the Pamlico Sound Bridge. With an Oregon Inlet bridge, demolition could be within the same contract as construction.

The NCDOT Standard Specifications, Section 402 – Removal of Existing Structures states that, "*Upon removal, all material are the property of the Contractor unless otherwise indicated on the plans or in the special provisions*." The contractor then becomes responsible for the safe and environmentally-responsible disposal of the materials. The NCDOT Standard Specifications, Section 802 – Disposal of Waste and Debris, outlines the state and federal requirements the contractor must comply with. In accordance with the NDCOT Standard Specifications, the contractor is required to submit a demolition plan for approval to insure that a safe method of bridge demolition will be undertaken. In addition, for bridges over water, the NCDOT requires that sawing and/or non-shattering methods be used such that debris will not fall into the water.

Demolition in the navigation zone in the Oregon Inlet would be coordinated with and comply with USACE and US Coast Guard regulations as related to working in, working over, and working adjacent to navigable waters. Specific timing and scheduling requirements outlined by the USACE, US Coast Guard, and any other affected regulatory agency would be followed.

Demolition of Bonner Bridge would require dismantling and removing the superstructure and substructure. All substructure components would be removed to at least 25 feet (7.6 meters)

below the mean low water elevation or possibly deeper as requested by the USACE in a letter dated January 16, 2001 (see Appendix A). The superstructure concrete deck would be broken into smaller pieces by sawing, jack hammering, etc. Deck pieces and superstructure girders would be loaded onto barges for towing to a disposal site. The footings and substructure also would be loaded onto barges for towing to a disposal site. The use of explosives during demolition is not anticipated. If explosives are needed to remove piles, the NCDOT would coordinate with the appropriate environmental resource and regulatory agencies to develop a blasting program that would minimize adverse effects to the natural environment.

The potential to recycle the construction materials from the demolished Bonner Bridge could be possible. Concrete, reinforced or un-reinforced, can be crushed and re-used as roadway sub-base material and aggregate for new concrete construction projects. Typically, the steel reinforcement is extracted from the concrete debris by means of a high-powered magnet. The reinforcing steel can then be sold as scrap steel to steel manufacturing companies to be re-formed into new steel products. Structural steel girders are recycled in a similar manner. Metal items such as bearing plates and railing also would be recycled. Currently, concrete and structural steel recycling facilities are both located in North Carolina and could be used as a potential location for delivery of construction materials for recycling. Other items, such as neoprene bearing pads, would be removed to a disposal site. If applicable, hazardous material procedures required by the NCDENR would be followed. There is no asbestos in Bonner Bridge.

Currently anticipated access options available include a combination of a dredged canal and either a haul road or a work bridge. A temporary haul road could be justified if it could be demonstrated that such access would not result in permanent impacts to marsh communities, these communities do not have an underlying organic subsoil, or if the cost of constructing and dismantling a temporary work bridge were so high that it would not be practicable to employ that methodology. A work bridge is feasible for demolition. As part of the demolition plan, the contractor would identify limits and dimensions of proposed haul roads, work bridges, and/or work barges required for bridge demolition work. Wetland and SAV areas would be identified in the demolition plan. Temporary work bridges could be required to span over the SAV and wetland areas, or a "top down" or overhead work method could be considered to protect SAV and wetland areas.

The majority of the materials removed, including cast-in-place and precast concrete elements, could be used in the construction of artificial reefs. If the old bridge is to be used as part of an offshore reef, it might need to be dismantled in large pieces; this would require the use of much larger equipment. The NCDOT would work with environmental resource and regulatory agencies prior to demolition to determine the most practicable construction access methodology for the demolition of Bonner Bridge. Impacts for demolition access would be determined and mitigated in concert with permitting agencies.

The DMF has suggested that concrete and steel bridge materials be placed on an artificial reef (or reefs). In subsequent conversations, the DMF (personal communication, October 21, 2003, Jim Francesconi, DMF) indicated that the bridge material should:

- Be free of oil, grease, or any petroleum-based residue, including asphalt and plastic products (unless encased in concrete), as well as lead (except lead-based paint);

- Have enough profile so that it would stay above the sea floor (generally greater than 3 feet [0.9 meters]). Small material can become buried during storms and would then not provide fish habitat; and

- Be concentrated in small areas on the reef site. A good way of deploying large amounts of concrete rubble is to use a hopper barge that opens and dumps the material in a pile. The material needs to be deployed properly to be effective.

Deployment of acceptable debris is done under an existing permit held by the DMF. The NCDENR Division of Coastal Management, DMF, and NMFS (as it relates to protected species) would be involved in disposal planning, and DMF staff would need to be on-site during disposal. Currently, there are four reef sites in the Oregon Inlet area. If enough material is available, a new reef site could be selected and a new reef created. If offshore disposal were not viable, the cost for removal of Bonner Bridge would be higher than what is described in Section 2.12. After demolition and removal is complete, approaches to Bonner Bridge and related fill would be removed and the sites restored to a condition similar to that of adjoining areas.

2.11.2 Removal of NC 12 Pavement

In addition to the demolition and removal of Bonner Bridge, existing and temporary NC 12 pavement replaced by the alternatives would be removed and disposed of in accordance with the latest version of the NCDOT's *Standard Specifications for Roads and Structures* (NCDOT, July 2006, or as current at the time of construction). The Standard Specifications indicate that salvageable materials, if approved by NCDOT, could be used in other parts of the construction as, for example, fill or sub-base. Depending on the construction sequencing and construction techniques chosen by the Design-Build Contractor, it is possible that some portion(s) of the pavement to be removed could be utilized in other areas of the project or potentially stockpiled for later use.

2.11.3 Future Demolition of Replacement Bridges

Future demolition of replacement bridges at the end of their design life would be in accordance with state and federal requirements for bridge demolition and removal at the time of removal. It is estimated that approximately 31,000 cubic yards of material per mile of bridge would be generated when the time comes to remove these bridges. The large majority of this material would be reinforced concrete. It is anticipated that most of the material would be recycled. No disposal difficulties would be expected with any of the alternatives, including those with a lengthy bridge component (Pamlico Sound Bridge Corridor and Parallel Bridge Corridor with All Bridge or with Phased Approach [including the Preferred Alternative]).

2.12 Costs and Funding

2.12.1 Project Costs

Table 2-9 and Table 2-10 show the total estimated costs through 2060 for the seven replacement bridge corridor alternatives under consideration. Construction, right-of-way, Bonner Bridge demolition, NC 12 pavement removal, and operation and maintenance costs are shown. Total costs for three different timeframes are shown.

Table 2-9. Highway Cost to 2060 (Low)

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge*	Phased Approach/ Rodanthe Nourishment
Highway Cost (2006 dollars)

[1] The cost for nourishment included in the Phased Approach/Rodanthe Bridge Alternative (Preferred) is representative of continued emergency maintenance activities in that area until Phase II is implemented.

*Preferred Alternative

2.12.1.1 Cost Range

Both low (Table 2-9) and high (Table 2-10) costs are shown. The low and the high reflect the potential range of costs as they are known at this time. The range for the bridge costs takes into account the following items that are unknown or for which only partial knowledge exists during the planning process:

- Geotechnical conditions;
- Site access, staging, and transport of materials constraints within and surrounding the project limits, particularly constraints requested by third parties that are unknown at this time;
- Permit conditions, including construction techniques that may be required or not be allowed by permits;
- Material availability, particularly for large orders to be filled on a demanding schedule;
- Material costs, noting that currently some suppliers are not providing cost estimates to contractors because of large product demand, especially if large orders must be filled on a demanding schedule;
- Final structural design criteria, especially as it relates to geotechnical and wave impact effects and that new wave action guidelines for design are currently being developed nationally;
- Variations in design approach that best suit individual contractors (e.g., one contractor may opt for long spans and fewer piers lending itself to segmental construction, while another contractor may have resources that would be better suited by a more traditional design approach; this is particularly true with the planned design-build procurement method);
- Effects of the upcoming implementation of the LRFD bridge code in North Carolina;
- The results of chloride modeling of a specific site, which would affect the content of the concrete used in project bridges;
- Risk assumptions in contractor estimates, including weather;
- Utility company needs as they affect schedule and cost;
- Final dredging needs; and
- The potential rate of erosion of sand nourishment sand.

2.12.1.2 Changes in Bridge Cost Assumptions since the SDEIS

The bridge costs (per square foot/per square meter) used for the 2006 cost estimates presented in Table 2-9 and Table 2-10 for the Oregon Inlet bridge (with the Parallel Bridge Corridor alternatives) and the Pamlico Sound Bridge Corridor bridge, reflect material unit costs solicited from three national bridge contractors, all of whom participated in the August 2006 Constructability Workshop (see Section 2.7). Costs developed by NCDOT were independently verified by FHWA and Finley Engineering (a private engineering firm). In Table 2-9 and Table 2-10, the low estimate for the Pamlico Sound Bridge Corridor bridge assumes conventional (concrete girder ["I" shape] superstructure) construction and the high estimate assumes segmental

(box girder superstructure) construction. The Oregon Inlet bridge estimates assume segmental construction only.

Bridge costs (per square foot/per square meter) for the Pamlico Sound Bridge Corridor bridge using conventional construction methods are consistent with data from the construction of the 2.8-mile (4.5-kilometer) long bridge on the US 17 Washington (North Carolina) Bypass over the Tar River (TIP Project No. R-2510). The bridge on the Washington Bypass is a design-build project that is currently under construction with an expected completion date of November 2010. Bridge costs for the Pamlico Sound Bridge Corridor bridge using conventional construction methods, the Oregon Inlet bridge, and the bridges for the NC 12 maintenance component of the Phased Approach alternatives (including the Preferred Alternative), were independently estimated by an engineering firm specializing in cost estimation of large bridge projects. These independent cost estimates support the 2006 estimates presented in Table 2-9 and Table 2-10.

The estimated 2005 cost to construct the Oregon Inlet bridge in Table 2-9 of the SDEIS was $191 million. The current (2006) cost estimate ranges from a low of $260 million (Table 2-9) to a high of $347 million (Table 2-10). The current estimate is higher than the SDEIS estimate because the SDEIS estimate was based on a conventional contract delivery method (the bridge is designed by NCDOT and a contractor is selected to build that design). The 2006 estimate utilizes a design-build contract delivery method (a contractor is selected to both design and build the project), as required by state legislation. This change resulted first in cost additions of five percent to complete the design of the project and 10 percent to reflect contractor risk. Second, this change resulted in 14.9 percent (5 percent per year) being added to cover inflation between 2005 and the midpoint of construction of the project based on a design-build contract start date of 2006. Adding an inflation factor in this way is the design-build cost estimate equivalent of assuming current year (2006) dollars when estimating the cost of a conventional contract delivery project. Similar design-build factors are used for the NC 12 maintenance components of the Parallel Bridge Corridor alternatives.

The estimated cost to construct the Pamlico Sound Bridge Corridor bridge presented in the SDEIS was $414.2 to $416.8 million depending upon the Rodanthe terminus option. The cost estimate range of $929.1 million to $1.4 billion presented in Table 2-9 and Table 2-10 is broader and reflects more than just a difference in terminus options. First, the range reflects the factors discussed in Section 2.12.1.1, as well as differences in superstructure type. Second, the costs include the design-build-related 5 percent design and the 10 percent risk increases, as well as an inflation factor of 18.7 percent (5 percent per year). The higher inflation factor than the Oregon Inlet bridge reflects the longer construction period assumed for constructing a Pamlico Sound Bridge Corridor project. Finally, the remainder of the difference reflects the elimination of assumptions made in 2005 related to economies of scale that now appear to be invalid. Initially, NCDOT and FHWA had determined that the cost of construction would be $55 per square foot ($5.1 per square meter), if erecting the bridge from barges, or $60 per square foot ($5.6 per square meter), if erecting the bridge from a work bridge. The 2006 cost estimate places the price at $130 to $140 per square foot ($12.1 to $13.0 per square meter) for conventional construction and $210 to $220 per square foot ($19.5 to $20.4 per square meter) for segmental construction.

2.12.1.3 Cost Comparison

The following observations can be made about the costs in Table 2-9 and Table 2-10:

- In terms of simply replacing Bonner Bridge with a new bridge, the shorter bridge over Oregon Inlet used with the Parallel Bridge Corridor would be the least costly ($260.0 to $347.0 million versus $929.1 million to $1.4 billion with the Pamlico Sound Bridge Corridor

bridge). However, the cost of the shorter Oregon Inlet bridge does not account for maintaining traffic from the bridge through Rodanthe; the NC 12 maintenance component must be included to truly compare the cost of the alternatives over the long-term.

- When the cost of NC 12 maintenance through the Refuge is added to the cost of a new Oregon Inlet bridge in the Parallel Bridge Corridor, as well as other highway-related costs until 2060, the Road North/Bridge South Alternative would be the least expensive ($602.2 to $740.2 million). The Nourishment Alternative is the second least expensive at $671.8 to $970.4 million. The remaining alternatives, which involve longer bridges, would range in cost from $1.1 to $1.8 billion.

- Right-of-way in Rodanthe would be most expensive ($15.5 to $73.6 million) with the Phased Approach alternatives (including the Preferred Alternative).

- Operation, inspection, and maintenance costs are greater for bridges than for roads. Inspection costs per square foot are expected to be higher when bridges are closer to the ocean and lower when bridges are over land.

- When costs through 2060 are discounted at a 5 percent discount rate, the Parallel Bridge Corridor with Nourishment Alternative becomes the least expensive. The Phased Approach alternatives (including the Preferred Alternative) become the least expensive alternatives involving bridges. The concept of discounting was explained in Section 2.6.3.3 under "Cost." As explained in that section, when the cost streams for the various alternatives are discounted, the costs of alternatives with higher up-front expenditures (e.g., un-phased alternatives) drop the least and the costs of alternatives with expenditures spread-out through 2060 (e.g., Nourishment and the Phased Approach alternatives [including the Preferred Alternative]) drop the most. With the latter, the costs are occurring closer to the time in which the benefits to the traveling public actually occur. Alternatives with lower discounted costs can be viewed as providing a better return on the investment of federal and state resources.

- The Parallel Bridge Corridor with Nourishment or Road North/Bridge South would involve the lowest near-term expenditures. The Road North/Bridge South Alternative could potentially offer even lower near-term expenditures if it was phased (see Section 2.10.2.5 under "Opportunities for Phasing the Road North/Bridge South and All Bridge Alternatives").

The nourishment costs shown in Table 2-9 and Table 2-10 for the Nourishment Alternative include a forecast low and forecast high rate of erosion of the material placed on the beach and the associated need to periodically replace newly eroded material. The cost through 2060, assuming the most likely erosion rate considered would be $429.4 million, in contrast with the low of $317.5 million and the high of $567.1 million shown in Table 2-9 and Table 2-10, respectively. In the case of nourishment associated with the Phased Approach alternatives (including the Preferred Alternative), the high cost also is considered the likely cost.

There is also the risk of a storm-created breach of Hatteras Island within the Refuge between now and 2060. A storm-created breach of Hatteras Island in the Refuge would separate almost all of Hatteras Island and its associated communities, tourism businesses, and the Cape Hatteras National Seashore from Bodie Island and the mainland. The cost of closing such a breach is discussed in Section 4.6.6, but is not included in the tables because although the potential for a breach exists, the occurrence of a breach (unlike shoreline erosion that can be predicted) is not a

certainty (see Section 3.6.3.4). In addition, there would be the associated economic loss, challenges for maintaining community services, and disruptions to daily living until the breach is closed. These economic costs of a breach are discussed in Section 4.1.5.4.

2.12.1.4 Potential Cost Sharing Opportunity with the Nourishment Alternative

The potential exists for reducing the cost of the nourishment component of the Nourishment Alternative shown in Table 2-9 and Table 2-10 by up to $20.0 million through 2060 if sand from the US Army Corps of Engineers' (USACE) ocean bar maintenance were used for nourishment and a cost sharing arrangement could be developed between the NCDOT and the USACE. The USACE is expected to continue to spend approximately $1,362,000 per year for contract hopper dredges to maintain the Oregon Inlet ocean bar channel. The USACE also has spent since 1989 an average of $1.53 million on pipeline dredges to maintain the channel in the vicinity of the navigation span of Bonner Bridge. The new Oregon Inlet bridge, which would have an approximately 3,300 to 5,000-foot-wide (1,006 to 1,524-meter-wide) navigation zone with a series of spans, could reduce navigation span maintenance requirements, reducing the USACE's dredging costs.

If arrangements could be made between the NCDOT and the USACE to cost-share the channel maintenance activities, the level of funding that the USACE may be willing to contribute could equal the expected costs for future contract hopper dredging, $1.362 million per year. This approach acknowledges that the replacement bridge would eliminate or greatly reduce USACE dredging cost under the Oregon Inlet bridge and the nourishment program could use sand down to the 14-foot (4.3-meter) authorized Oregon Inlet channel depth, which is not currently achieved (as described in Section 2.10.2.1).

The cost included in Table 2-9 and Table 2-10 for nourishment in the northern part of the Refuge (at the ponds and north of the ponds) is $182.7 to $320.4 million of the $317.5 to $567.1 million shown. If material was used for nourishment from the USACE's ocean bar dredging program, mobilization costs for nourishment would be higher than assumed in the cost in Table 2-9 and Table 2-10 because the sand would become available annually and the costs in Table 2-9 and Table 2-10 assume mobilization for nourishment every four years. Increased mobilization costs would increase the cost of nourishment in the northern part of the Refuge by $49.5 million. The total USACE contribution through 2060 would be $69.5 million based on the annual contribution noted in the previous paragraph. Thus, such a partnership between the USACE and the NCDOT would reduce the cost of the Nourishment Alternative by up to $20.0 million through 2060.

2.12.2 Bonner Bridge Demolition and Removal Costs

Demolition and removal of Bonner Bridge would cost approximately $4 million (2006 dollars). This cost can vary greatly depending on accessibility and the location of an acceptable site for disposal of those items that cannot be recycled or disposed of economically.

2.12.3 Other Public Costs

The highway costs shown do not include other non-highway costs, such as the potential public cost of providing alternative access to the Refuge with the Pamlico Sound Bridge Corridor. A sample of these public costs is provided in Table 2-11 and Table 2-12. Again, a low (Table 2-11) and a high (Table 2-12) cost table is presented. The non-highway and alternate access cost estimates are identical in the two tables. Both tables are included so that the combination of these costs with the range of highway costs presented in Table 2-9 and Table 2-10 can be shown.

Table 2-11. Non-Highway Public Cost and Total Highway Cost (Low) to 2060

	Pamlico Sound Bridge Corridor		Parallel Bridge Corridor				
	Curved Rodanthe Terminus	Intersection Rodanthe Terminus	Nourishment	Road North/Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge*	Phased Approach/ Rodanthe Nourishment

*Preferred Alternative

All or part of the non-highway costs may be borne by the FHWA and NCDOT, including some utility costs, cost of removing the terminal groin, and the cost of relocating the (former) Oregon Inlet US Coast Guard Station (if required as a part of mitigating the loss of access associated with the Pamlico Sound Bridge Corridor alternatives). The following can be observed about these costs:

- Utility relocation costs would be greatest with the Pamlico Sound Bridge Corridor because the costs of placing electrical lines over water are more expensive than over land. The utility costs for the Parallel Bridge Corridor alternatives assume that utilities are relocated onto the new Oregon Inlet bridge and elsewhere utilities are relocated as needed, on land, and within the Refuge.

- Terminal groin removal is shown for the Pamlico Sound Bridge Corridor because the groin would not be needed with this alternative. Others may choose to obtain a new permit to retain the groin if the Pamlico Sound Bridge Corridor is chosen for implementation.

- Retention of the groin with the Parallel Bridge Corridor alternatives would allow the (former) Oregon Inlet US Coast Guard Station to remain in place.

- The USFWS will need to relocate its Visitor Center as the shoreline erodes with all alternatives except the Nourishment Alternative, which would maintain the existing shoreline as needed to protect NC 12.

The Refuge costs recognize that with the Pamlico Sound Bridge Corridor, the NCDOT would no longer need to maintain NC 12 in the Refuge to retain access to Hatteras Island south of the Refuge and that Refuge representatives have indicated that they would prefer a type of access that did not involve regular storm-related maintenance. The options listed are possibilities suggested in the past by Refuge officials and reflected in the Refuge's *Comprehensive Conservation Plan* (USFWS, 2006), alternatives 4 and 5. In addition to the options presented here, the Refuge could designate a sand route for private vehicles at presumably a nominal cost in contrast with the options presented in Table 2-11 and Table 2-12. Also, these options do not consider costs if a storm-caused breach were to occur at the southern end of the Refuge. If this were to occur, a ferry service would need to be implemented to get visitors, and perhaps their vehicles, to and from the Refuge.

The following can be observed about the costs of alternate Refuge access:

- Operating a ferry to the north end of Hatteras Island from Bodie Island would be a high cost strategy at $500 million through 2060. This cost includes the actual ferry operations costs as well as regular maintenance dredging.

- A tram service would be the least costly strategy based on the assumptions used to develop the cost (trams serving 620 passengers per day for 4 months with 20 minute headways, 310 per day for 4 months, and 155 per day for 4 months or an annual capacity of 132,000). The Refuge has an estimated 400,000 to 500,000 annual visitors.

- Partial road access also would be a high cost strategy at $179 to $254 million through 2060.

The combination of additional potential non-highway and Refuge access costs would increase Pamlico Sound Bridge Corridor costs (the most expensive alternative even when considering only highway costs) from $1.3 to $1.8 billion to as high as $1.9 to $2.4 billion.

2.12.4 Capital Funding

The funds to build one of the replacement bridge corridor alternatives are expected to come from two sources:

1. The funds allocated in NCDOT's approved 2009 to 2015 TIP for construction of the proposed project; and

2. In the case of the two Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) and the Parallel Bridge Corridor with Nourishment Alternative, spreading the cost over multiple federal and state funding cycles.

Many states use innovative techniques to finance large projects or transportation improvement programs. They all involve the issuance of revenue bonds against one or more long-term sources of revenue. Revenues used to pay the principle and interest associated with the bonds can come from future FHWA Federal-Aid funds, state transportation revenues (e.g., motor fuel taxes), local taxes, local fees, and tolls. The US Department of Transportation also can loan monies that are in addition to the federal transportation funds normally apportioned to the state. In this case, repayment must come from non-federal sources. In North Carolina, the opportunities for such financing that is available to NCDOT Division 1, where the project is located, would not be adequate to fund the proposed project.

The State of North Carolina Highway Trust Fund Act of 1989 (GS 136-175 to 136-184) created the North Carolina Highway Trust Fund. This Act states that the Highway Trust Fund shall be used for the following purposes:

1. For the planning, design, and construction of the North Carolina Intrastate System specifically described in GS 136-178;

2. For the planning, design and construction of the Urban Loops described in GS 136-179;

3. For a supplement to secondary road construction as described in GS 136-180; and

4. For a supplement to the NCDOT's TIP.

The Act also identified the sources of funding for the Highway Trust Fund (GS 136-177) and established a distribution formula (GS 136-184) by which the transportation funds would be distributed to seven "Distribution Regions" of the state, each region consisting of two NCDOT Highway Divisions. The purpose of this distribution formula, also known as the "Equity Formula," was to spread transportation funds throughout the state. Under the Equity Formula, all state and federal funds allocated for construction of projects under the NCDOT's TIP in each Distribution Region shall be determined by "multiplying the total amount of the funds available for that seven-year period for the construction of these projects by a factor based: 25 percent on the miles to complete the Intrastate System within the Distribution Region as compared to the miles of the entire Intrastate System; 50 percent on the population of the Distribution Region compared to the total population of the State; and 25 percent on an equal share based on the number of Distribution Regions (one-seventh)."

Based on the Equity Formula, NCDOT Division 1 received approximately $548 million in funding from NCDOT's 2007 to 2013 TIP (current at the time this analysis was conducted). Therefore, Division 1 does not currently have sufficient funding available in the seven-year period to *completely* build the Pamlico Sound Bridge Corridor or any of the Parallel Bridge

Corridor alternatives (see Table 2-9 and Table 2-10). Furthermore, State law prohibits exceeding the funds allocated by the Equity Formula in one TIP period. Applying the Equity Formula to projected future transportation funds indicates that Division 1 would not exceed $1 billion in cumulative funding until 2021. Therefore, Division 1 would only have sufficient funding to completely build the Nourishment Alternative and the Road North/Bridge South Alternative (and then only in phases) through at least 2021.

The NCDOT considered several innovative financing techniques to fund the Bonner Bridge replacement, including the State Infrastructure Bank, toll roads, and GARVEE Bonds. The State Infrastructure Bank is a low interest loan program that NCDOT administers primarily to municipalities. The program has $1.5 million and currently $1.2 million is loaned, leaving $200,000 available mainly for cities and counties. NCDOT has not utilized the State Infrastructure Bank for one of its own projects.

Another innovative financing technique considered was toll roads. However, State law requires that a free route be available as an alternative to a toll road. Currently NC 12 to Bodie Island is the only free route connecting Hatteras Island to the mainland. The North Carolina Turnpike Authority (NCTA) is not considering the Bonner Bridge replacement as a potential toll project.

The final innovative financing technique considered was GARVEE Bonds, which are transportation bonds issued by the state against future federal funding. NCDOT had sought legislation that would have allowed for GARVEE Bonds to construct this project and other very costly projects; however, the statute that was approved by the state legislature dictated that the bond money be distributed according to the Equity Formula. Therefore, of the initial $950 million bond offering, only $76 million is allocated to Division 1, and this entire amount is currently allocated to the Bonner Bridge project. Approximately $55 million will go towards the replacement bridge, and the balance will be used to repair Bonner Bridge to facilitate its continued use until the replacement bridge is built.

As stated above, NCDOT Division 1 is projected to receive $548 million in equity funds from federal and state sources over the next seven years. Since the GARVEE Bonds funds of $55 million are from a bond, the State will be repaying the debt service over the next 12 years, which reduces the actual purchasing power, so there is only a $27 million net gain in funding that can actually go towards the proposed project from the GARVEE Bonds. Therefore, a total of $575 million can be used on projects in Division 1 over the next seven years.

Based on the initial $950 million bond offering from the GARVEE Bonds and the Division's $548 million apportionment from the 2007 to 2013 State TIP, each of the replacement bridge corridor alternatives could have been cost-feasible to build if the Equity Formula had not been applied. However, because the Equity Formula would apply, NCDOT does not have a means in which the State could generate enough funds for Division 1 to be able to *completely* build the Pamlico Sound Bridge Corridor or any of the Parallel Bridge Corridor alternatives in one seven-year State TIP period. However, the Parallel Bridge Corridor alternatives could be phased (i.e., the costs spread-out over time). For example, the replacement bridge construction costs for the Parallel Bridge Corridor alternatives (i.e., the Oregon Inlet bridge components) in both tables ($260.0 to $347.0 million) are less than the $575 million that is currently available. For the Phased Approach alternatives (including the Preferred Alternative), the construction of the new Oregon Inlet bridge corresponds to Phase I (see Section 2.10.2.5). The four phases of the Phased Approach alternatives (including the Preferred Alternative) were developed primarily to address future forecast coastal conditions, but the issue of funding availability was also a consideration in the decision to phase these alternatives.

2.12.5 Short-Term NC 12 Maintenance Costs Expected Prior to Implementation of the Phased Approach Alternatives

From August 1999 to October 2007, NCDOT spent approximately $5.5 million on major actions to restore NC 12 after storm events. Of that amount, approximately $3.9 million was spent within the Refuge, predominantly at the three hot spots. The greatest expenditures within the Refuge occurred in 1999 (approximately $1.7 million) in association with Hurricanes Dennis, Bonnie, and Floyd, and in 2003 (approximately $1.2 million) in association with Hurricane Isabel. From 2004 to 2007, major restoration costs totaled approximately $1.1 million over the four years. No substantial costs occurred between 2000 and 2002. Lesser levels of NC 12 weather-related maintenance occur on a regular basis for which specific costs are not available. They include in recent years road scraping 1 to 2 times per month and minor dune maintenance 2 to 3 times per year (see Table 4-15). These activities are concentrated in the three hot spots: 'S' Curves, Sandbag Area, and Canal Zone.

The extent of expenditures for NC 12 weather-related maintenance in any given year is highly dependent on whether major storms occur. As indicated in Section 4.6.8.6, as the shoreline evolves between now and the completion of Phase II, maintenance needs in the hot spots are expected to increase, and the cost of new storm events are expected to rise as the potential increases for larger areas to be affected by storms (see Table 4-15 and Table 4-16).

Once Phase II is complete, it is expected that NC 12 weather-related maintenance (and its associated cost) would drop substantially, since all three hot spots would be bridged (see Table 4-15 and Table 4-16). Costs would again rise as more maintenance is required with shoreline change prior to the completion of Phases III and IV. As indicated in Section 2.10.2.5, NCDOT intends to implement a monitoring program in the Phase III and IV areas, as well as in the 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge that is not expected to be threatened by erosion prior to 2060, so as to time the implementation of Phases III and IV (to the extent practicable given the availability of transportation funding and the efficient use of those funds) such that the need for future NC 12 maintenance in those areas is reduced. Thus, high levels of NCDOT weather-related maintenance costs are not expected to return after Phase II is complete; however, accelerated sea level rise and increased storm activity (magnitude and frequency) could change these expectations. A monitoring program described in Section 2.10.2.5 would help minimize the effect of such change.

2.13 Environmental Protection during Construction and Demolition

Best Management Practices (BMPs) to control erosion, sedimentation, and stormwater runoff would be used during construction and Bonner Bridge demolition. BMPs are discussed in Section 4.13.7.

The use of explosives during construction and Bonner Bridge demolition is not anticipated. If explosives are needed to remove Bonner Bridge's piles, the NCDOT would coordinate with the appropriate environmental resource and regulatory agencies to develop a blasting program that would minimize adverse effects to the natural environment.

Environmental protection-related specifications contained in the NCDOT's *Standard Specifications for Roads and Structures* (July 2006 or latest revision) would be incorporated into

construction contracts. The types of environmental specifications that would be included in construction contracts are:

- Observance of and compliance with all federal, state, and local laws, ordinances, regulations, orders, and decrees that affect the conduct of the construction work.

- Traffic maintenance within the limits of the project, including existing roadways that cross or intersect the project. During peak season in the summer, two lanes would be maintained. The construction work would be conducted in a safe manner that creates a minimum amount of inconvenience to traffic. Continuous and safe access would be provided to adjoining activities, and operations would be conducted such that the inconvenience to property owners and users is limited.

- Implement measures to minimize the dust generated by construction, when the control of dust is necessary for the protection and comfort of residents, motorists, and campers. Construction contractors would take measures necessary to minimize air pollution. Dust control is not considered effective where the amount of dust creates a potential or actual unsafe condition, public nuisance, or condition endangering the value, utility, or appearance of surrounding properties.

- Development and implementation of a soil erosion schedule. It would describe the time relationship between phases of the work that must be coordinated to reduce erosion, construction practices, and temporary control measures that would be used to minimize erosion. Contractors must take whatever measures are necessary to minimize soil erosion and siltation.

- Incorporation of all permanent erosion control work into the project at the earliest practicable time and coordination of temporary measures to ensure economical, effective, and continuous erosion control.

- Seeding and mulching on all earth areas disturbed by construction on a section-by-section basis, immediately upon completion of each section.

- Proper disposal of waste and debris outside the project right-of-way. A plan for the disposal of waste materials also would be developed. Disposal in areas under the jurisdiction of the USACE regulatory jurisdiction would not be allowed unless the contractor obtains the required permit and coordinates with other pertinent agencies. When public waste and disposal areas are not used, waste would be disposed of in areas compatible with such disposal, covered with earth, and shaped into contours that are comparable to, and blend in, with the existing topography. The covered waste areas would be seeded and mulched. Erosion would be controlled. Any burning of debris would be in accordance with applicable local, state, and federal laws and ordinances.

- Exercise every reasonable precaution to prevent pollution of water bodies, including proper storage of any fuel or hazardous materials and following required emergency response procedures in the event of a hazardous waste or oil spill.

Excavated, dredge, and fill material generated by the proposed bridge construction generally would be disposed of using one or more of the techniques that have been used regularly in the Oregon Inlet area in past years: open water disposal, diked as well as undiked disposal areas, and beach nourishment. These techniques and possible disposal locations associated with these

techniques are described in Section 4.13.5. The appropriate location for disposal would be determined based on the character of the materials dredged, the availability of disposal sites, and coastal conditions near the time of construction. All of this information would be sought during USACE permit preparation.

2.14 Permits and Approvals

Various regulatory agencies were contacted to identify specific permit requirements, to solicit input into the assessment of potential environmental impacts, and to begin the permit coordination process. Permits would be needed from:

- The US Coast Guard (Norfolk District Bridge Section);
- The USACE (Wilmington Field Office);
- The USFWS;
- The NCDENR's Division of Coastal Management;
- The NCDENR's Division of Water Quality; and
- The NPS, Cape Hatteras National Seashore, Manteo.

These permits, as well as permitting issues as they pertain to the seven replacement bridge corridor alternatives, are described below. Coordination with permitting agencies was initiated at an agency scoping meeting on June 19, 1991, and at a joint permitting agency meeting on July 11, 1991. Another coordination meeting with the NPS and the USFWS was held August 29, 1995. A November 13, 2002, meeting with the NPS and the USFWS discussed permitting issues related to the Refuge and the Seashore.

Permitting-related issues also were discussed at the February 12, 2003 and July 23, 2003, NEPA/Section 404 Merger Team meetings. These meetings were attended by state and federal environmental resource and regulatory agencies. Permitting issues were discussed at January 7 and April 5, 2005 meetings with several regulatory agency representatives that were a part of developing the Parallel Bridge Corridor with NC 12 Maintenance alternatives, as well as at a May 24, 2005 briefing of the NEPA/Section 404 Merger Team. Coordination with permitting agencies would continue throughout the proposed project design and the permit application process, as well as during project construction. This coordination will help ensure the development of an environmentally sensitive design reflecting any changes in project area conditions that might occur following completion of the EIS process.

US Coast Guard Permit

A bridge permit for either the Oregon Inlet or Pamlico Sound bridge would be required from the US Coast Guard. Under the authority of Section 9 of the Rivers and Harbors Act of 1899 and the General Bridge Act of 1946 (as well as other legislation), the Coast Guard is responsible for approving the locations and plans for bridges and causeways over navigable waterways.

US Army Corps of Engineers Permit

The USACE Sections 404 and 10 permits and the NCDENR, Division of Coastal Management CAMA permit can be obtained through a joint permit application process (general permit 291). For this project, however, separate Section 404 and Section 10 permits must be obtained. Under Section 404 of the Clean Water Act, the USACE is responsible for issuing permits for discharges of dredged or fill material in the waters of the United States, including fill placed in connection with bridge and road construction and disposal of construction debris. The wetlands that would be filled by the five replacement bridge corridor alternatives and mitigation options are discussed in Section 4.7.4.

Section 103 of the Marine Protection, Research, and Sanctuaries Act of 1972 regulates ocean dumping of dredged material. If this disposal methodology is used, this permit would be obtained. The Secretary of the Army can issue a permit after it has been determined that the dumping would not unreasonably degrade or endanger human health, welfare, or amenities, or the marine environment, ecological systems, or economic potentialities.

US Fish and Wildlife Service Permits and Compatibility Determination

Depending on the Parallel Bridge Corridor Alternative selected, the permits required from the USFWS would include:

- Right-of-Way Permit (when leaving the current easement);
- Special Use Permit (for temporary impacts because of construction, temporary detours, and beach nourishment); and
- A new permit for the retention of the terminal groin and revetment because the permit granted for the construction of the terminal groin states that the groin's intended use is only to protect the Bonner Bridge.

With the Phased Approach/Rodanthe Bridge Alternative (Preferred), only the new groin permit would be required because the project would be confined to the current easement.

With the exception of the Phased Approach/Rodanthe Bridge Alternative (Preferred), the alternatives in the Parallel Bridge Corridor could occur only if the USFWS concluded that the alternative is compatible with the April 1938 Executive Order 7864, which reserved the Refuge to advance the purposes of the Migratory Bird Conservation Act, and the National Wildlife Refuge System Improvement Act of 1997. Without such a compatibility determination, the USFWS could not issue a permit for the construction of a project on new alignment within the Refuge or a long-term beach nourishment program.

Also, with the Pamlico Sound Bridge Corridor, a new Special Use Permit for the retention of the terminal groin and revetment would be required if it is to remain in place. Without a new permit, the NCDOT would be obligated under the terms of the existing permit to remove the terminal groin and revetment two years after the construction of a replacement bridge at the request of the USFWS. The terminal groin and revetment would not be needed to protect a replacement bridge in the Pamlico Sound Bridge Corridor.

Coastal Area Management Act Permit

A CAMA permit would be required since all alternatives would involve construction along the oceanfront and in an area of environmental concern (AEC). The Pamlico Sound Bridge Corridor would affect coastal wetlands. The extent of impact on coastal wetlands is discussed in Section 4.7.4.

NCDENR, Division of Water Quality Certification

A 401 Water Quality Certification (as mandated under Section 401 of the Clean Water Act) would be required from the NCDENR Division of Water Quality. The 401 certification process is coordinated with the 404 and CAMA processes.

National Park Service Special Use Permit

An NPS special use permit would be obtained to use NPS lands at a bridge terminus on Bodie Island. In the Refuge area, the NPS would be involved in any permitting decisions related to the Refuge for the area outside the mean low tide level (the Refuge's ocean-side boundary) because the NPS property extends 150 feet (45.7 meters) beyond the shoreline. The permit would be issued by the Seashore Superintendent. The Superintendent must conclude that the bridge would not impair park resources.

2.15 Preferred Alternative

On August 27, 2007, representatives of NCDOT, FHWA, USACE, and NCDENR identified the Phased Approach/Rodanthe Bridge Alternative (Preferred) as the Least Environmentally Damaging Practicable Alternative (LEDPA) for replacing the Bonner Bridge under the project's NEPA/Section 404 merger process (see Appendix D for the signed agreement). The LEDPA has been adopted as the Preferred Alternative by NCDOT and FHWA. As described in Section 2.10, the Phased Approach/Rodanthe Bridge Alternative (Preferred) proposes replacing the Bonner Bridge with a parallel bridge and maintaining existing NC 12 through the Refuge by building bridges as needed in the existing NC 12 easement. Agency representatives based their decision on each alternatives' ability to meet the project's purpose and need, environmental consequences, opportunities available to mitigate impacts, cost, public and agency comment on the findings of the SDEIS and SSDEIS, and other findings presented in this FEIS. Agency representatives concurred that the Pamlico Sound Bridge Corridor is not a practicable alternative because of the high cost estimates and the impracticality of phasing this alternative, and therefore is not the LEDPA.

Specifically, the agencies concurred that:

- The Pamlico Sound Bridge Corridor is not practicable based on cost estimates and thus is not the LEDPA;
- Phase I of the project should be to construct the replacement bridge within the Parallel Bridge Corridor as soon as possible, every effort should be made to place the new bridge terminus within the existing easement, and Phase I should be advanced through the merger process;
- Phase I of the Phased Approach/Rodanthe Bridge Alternative (Preferred) alone would not meet the purpose and need of the project;
- Phases II to IV present substantial challenges to obtaining permit approvals; and
- At the time of permit application of Phases II to IV (see Section 2.14 for a discussion of needed permits), reasonable, practicable, and feasible alternatives will be considered and evaluated in pursuit of the LEDPA/Preferred Alternative.

Although agency representatives selected the Phased Approach/Rodanthe Bridge Alternative as the Preferred Alternative, they recognized that the project area is complex and the shoreline is

constantly changing. They noted that the ability to predict the effect of future storms on the project area is extremely difficult to quantify, and they agreed that the various alternatives may need to be reassessed in the future as the shoreline and other landscape changes.

The concurrence form is presented in Appendix D. A description of the NEPA/Section 404 Merger Team meetings associated with the selection of the Preferred Alternative is presented in Section 8.10.

In addition to the reasons listed in the concurrence form, the Phased Approach/Rodanthe Bridge Alternative (Preferred) also:

- Could be phased and built as funding became available;
- Would meet the project's purpose and need;
- Would ultimately allow natural shoreline processes to occur between Oregon Inlet and Rodanthe, with the exception of the continued presence of the terminal groin;
- Would ultimately end regular storm-related NC 12 maintenance in the Pea Island National Wildlife Refuge, including substantially decreasing such maintenance after the complete of Phase II;
- Would bridge potential island breach locations; and
- Would provide continued road access to the Refuge.

Chapter 3

Affected Environment

3.0 Affected Environment

This chapter describes the existing conditions and characteristics in the project area that could be affected by the Bonner Bridge replacement. The characteristics described are those relevant to the assessment of impacts presented in Chapter 4. As appropriate to the assessment of impacts, the information presented under each topic focuses on the project area, the community of Rodanthe, the Cape Hatteras National Seashore, the Pea Island National Wildlife Refuge, Oregon Inlet, Pamlico Sound, and Dare County in general. The following topics are addressed:

- Community beginning on page 3-1;
- Environmental Justice beginning on page 3-22;
- Visual Characteristics beginning on page 3-22;
- Cultural Resources beginning on page 3-27;
- Parks and Recreation beginning on page 3-34;
- Coastal Conditions beginning on page 3-49;
- Natural Systems beginning on page 3-68;
- Mineral Resources on page 3-109;
- Air Quality beginning on page 3-109; and
- Noise beginning on page 3-111.

3.1 Community

3.1.1 Regional Setting

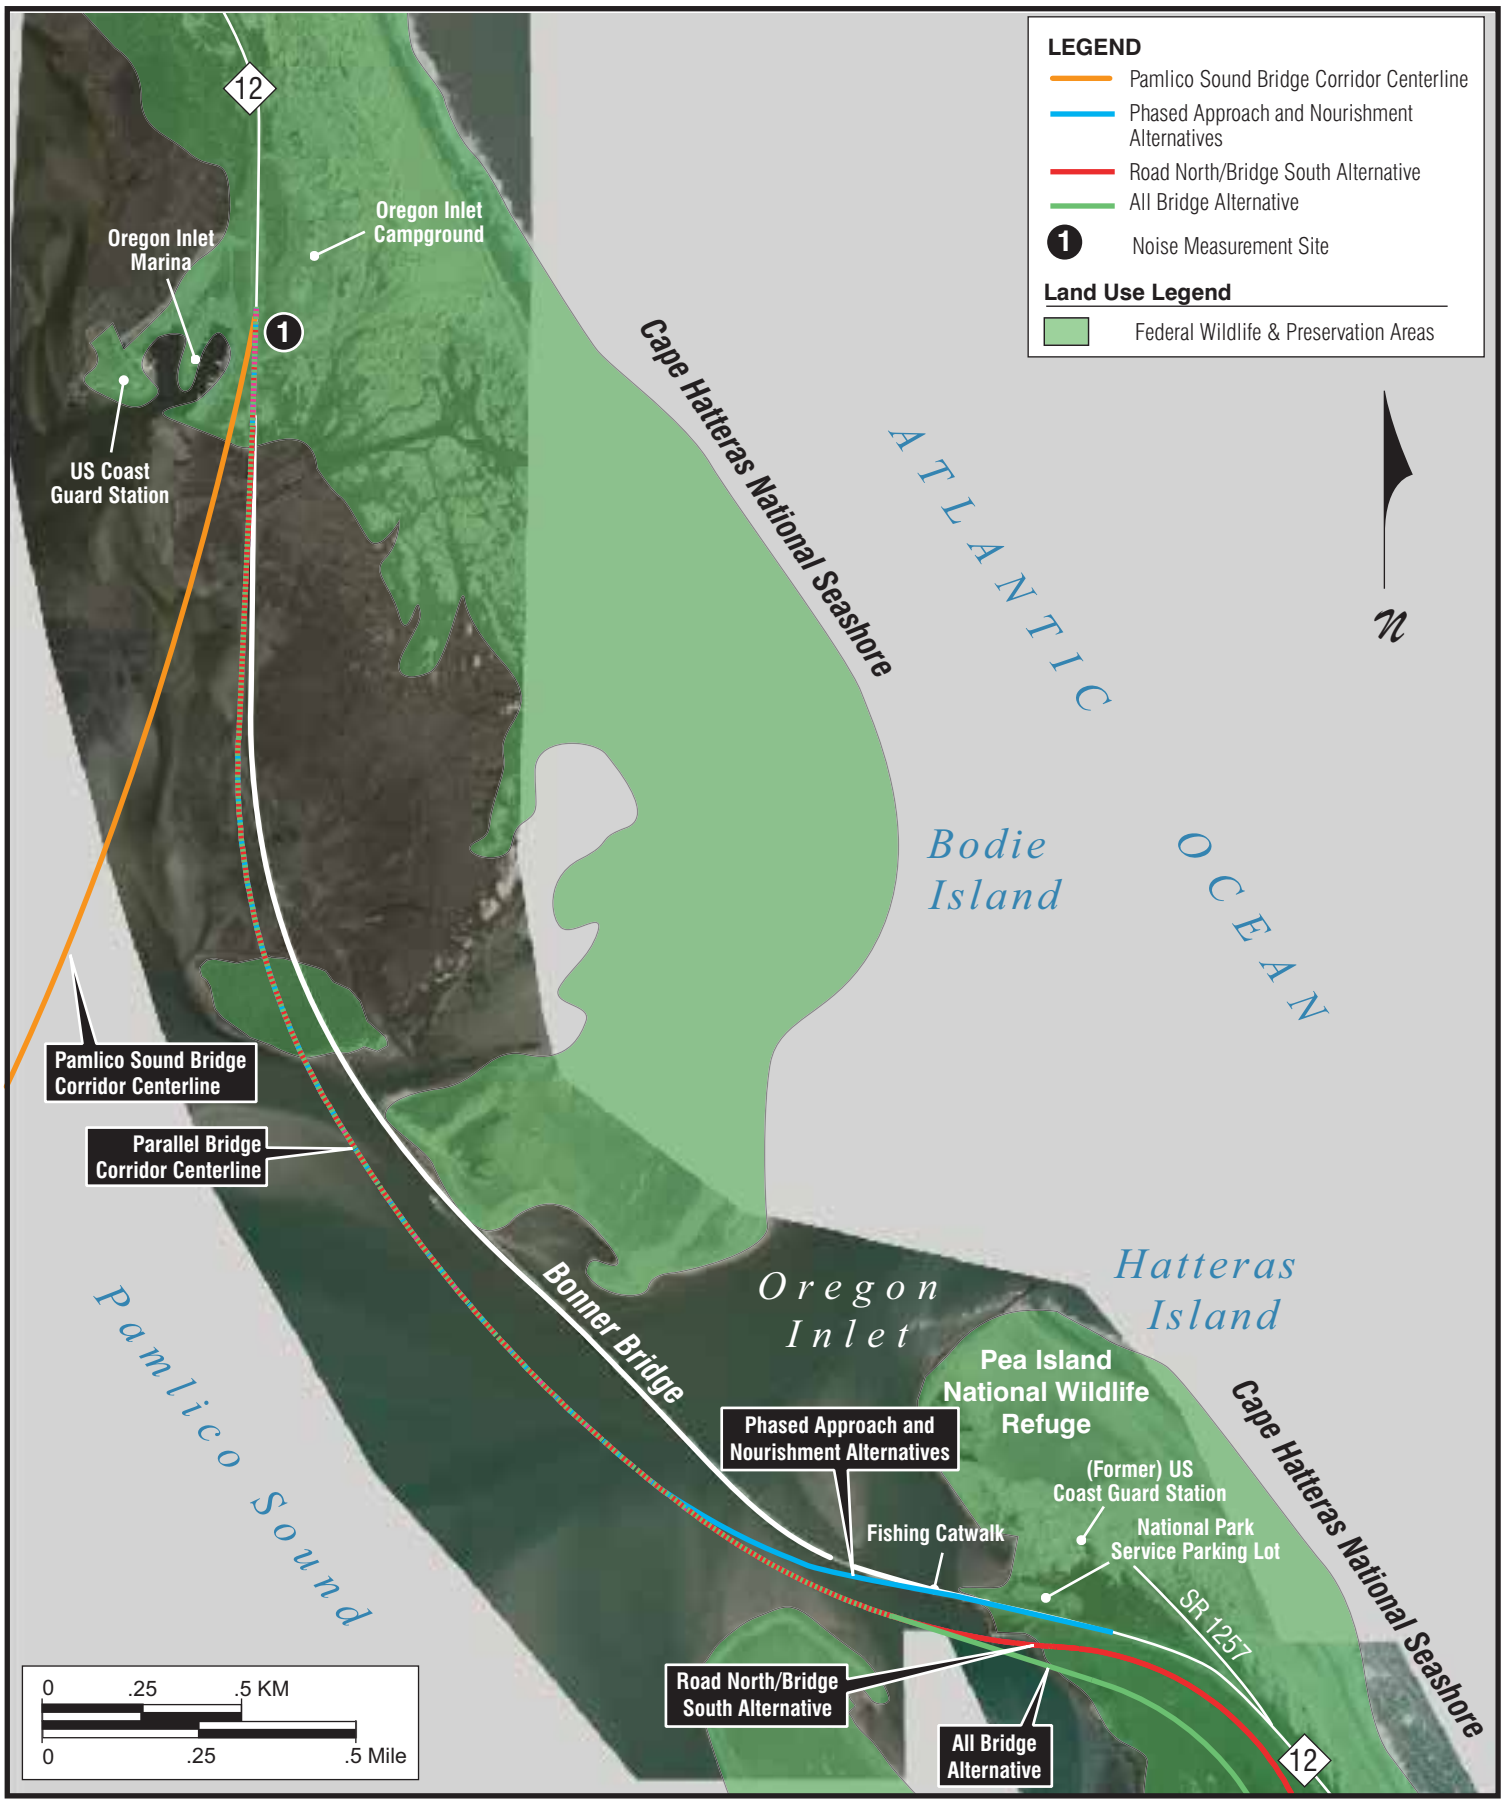
The project area is in Dare County in eastern North Carolina. The project area encompasses northern Hatteras Island, the southern end of Bodie Island, and regions of the Pamlico Sound (see Figure 1-1). NC 12 is the only major road traversing the region. It runs north-south through the entire project area. Dare County's population was 29,967 in 2000, increasing 32 percent between 1990 and 2000. The area's economy is highly dependent on tourism-related activities, and the peak visitor numbers for Dare County have undergone a steady increase over the last 23 years. For 2002, it was estimated to be as high as 232,000 during the day and 126,000 at night during peak summer periods (*Outer Banks Economic and Demographic Package*, Outer Banks Chamber of Commerce, 2003).

The most developed area of the barrier islands in Dare County is the northern portion of Bodie Island, which includes the communities of Nags Head, Whalebone, Kill Devil Hills, and Kitty Hawk. With the development of much of Bodie Island, there has been a recent movement of

construction and development to Hatteras Island in the small communities of Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, and Hatteras Village. NC 12 and Bonner Bridge connect Bodie Island, Hatteras Island and, via a ferry, Ocracoke Island. Much of the southern portion of Bodie Island, as well as most of Hatteras Island, are within the Cape Hatteras National Seashore. The northern end of Hatteras Island includes the Pea Island National Wildlife Refuge.

3.1.2 Land Use

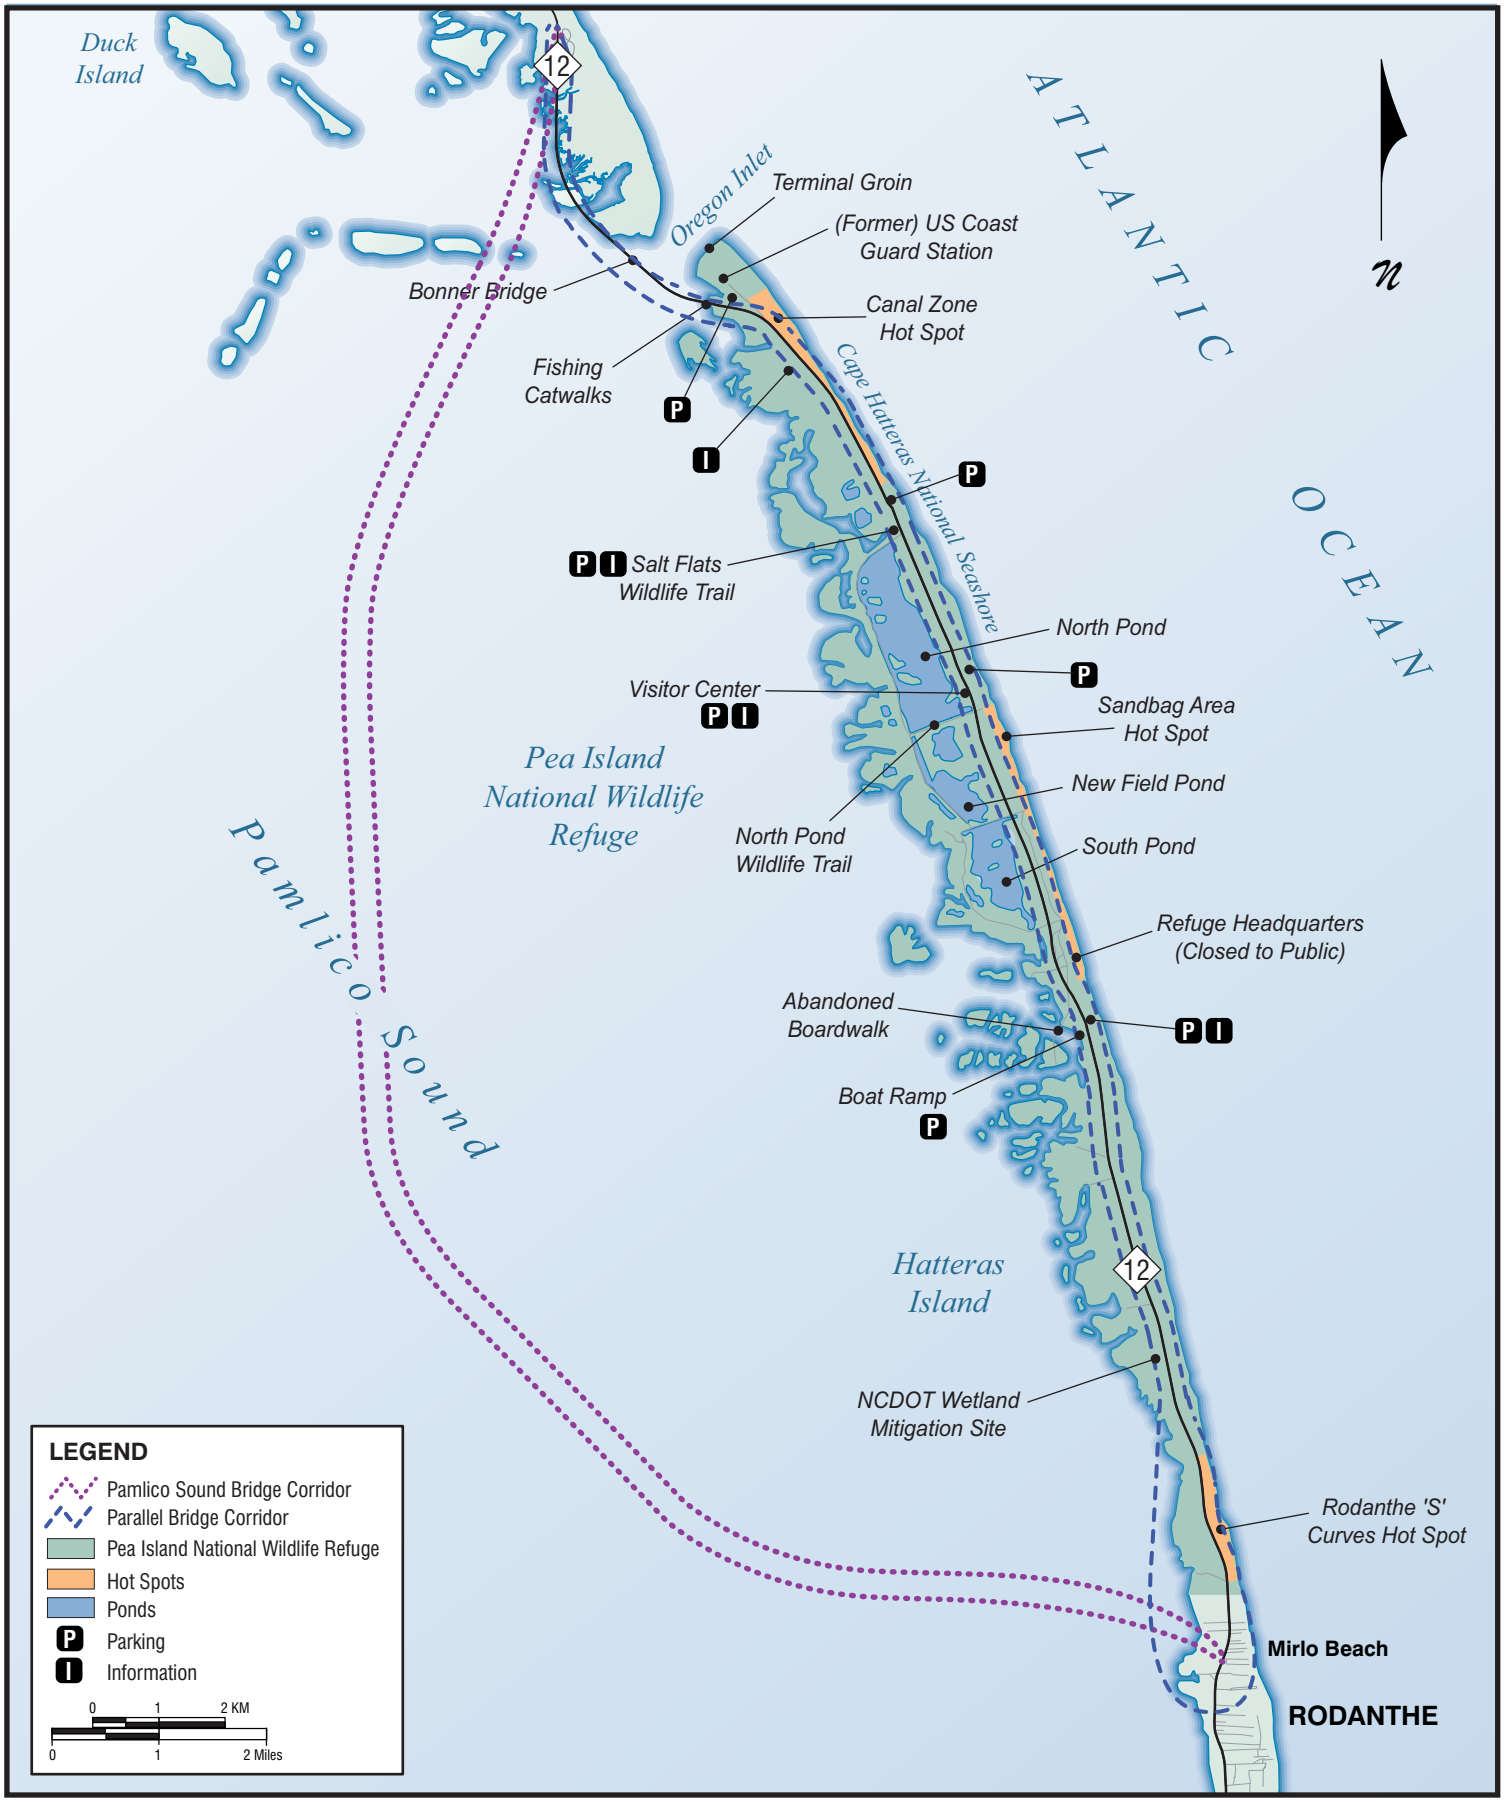
The project area encompasses the southern tip of Bodie Island at the northern terminus of Bonner Bridge and the northern portion of Hatteras Island as far south as the community of Rodanthe. Land use in the project area is shown in Figure 3-1a through Figure 3-1c.



Bodie Island forms the northern shoulder of the Oregon Inlet and is a part of the Cape Hatteras National Seashore (Seashore), which is administered by the National Park Service (NPS). The southern end of Bodie Island, including the Oregon Inlet campground and the Oregon Inlet Marina and Fishing Center, is used for recreation. The active Oregon Inlet US Coast Guard Station is also in this area.

South of Bonner Bridge are Hatteras Island and the Pea Island National Wildlife Refuge (Refuge). The Refuge lies within the boundaries of the Seashore and is administered by the US Fish and Wildlife Service (USFWS). Refuge facilities include wildlife trails, a Visitor Center, a boat ramp, and headquarters buildings. There are catwalks used by fishermen on the south end of Bonner Bridge. A NPS parking lot is also near the south end of the bridge. The USFWS is responsible for wildlife management within the Refuge, and the NPS is responsible for Seashore visitors and visitor facilities. The Refuge consists primarily of barrier island beach, dunes, and coastal wetlands. A (former) US Coast Guard Station building also is at the northern end of Hatteras Island. The Station is listed on the National Register of Historic Places (NRHP).

The community of Rodanthe is at the southern end of the project area. Development has occurred such that there is no clear distinction between Rodanthe and the adjoining communities of Waves and Salvo. Commercial development in Rodanthe exists along NC 12 and consists mostly of small service stations that also serve as general stores, realty agencies, restaurants, and businesses for recreational activities. An automobile junkyard, which is part of an automobile parts business, is located west of NC 12 in Rodanthe. Junked cars were removed from a part of it in 2003 and 2004. Residential development focuses on the oceanfront on the east and Pamlico Sound on the west and primarily consists of large multiple-story, multiple-bedroom rental vacation home neighborhoods; however, there are also scattered neighborhoods of smaller, often one-story, permanent homes. A desalinization plant run by Dare County opened in 1996 in Rodanthe and has eliminated the communities' general dependence on private wells for potable water. The Chicamacomico Life Saving Station, a museum listed on the NRHP, is in Rodanthe on the east side of NC 12. The Rodanthe-Waves-Salvo Community Center is on the west side of NC 12.



Six other communities are on Hatteras Island south of the project area:

- Waves;
- Salvo;
- Avon;
- Buxton;
- Frisco; and
- Hatteras Village.

Figure 3-1c

3.1.3 Land Use Planning

This section describes area plans. The area that would be affected directly by construction of a bridge is within the jurisdiction of the Coastal Area Management Act (CAMA), Dare County's land use plan, the NPS's plan for the Seashore, and the USFWS's Refuge management plan. No new Seashore, Refuge, or US Coast Guard facilities are planned in the project area.

3.1.3.1 Coastal Area Management Act

The Coastal Zone Management Act (CZMA) was passed by Congress in 1972. This legislation relies on voluntary measures and incentives to encourage federal, state, and local partnerships for coastal protection. This program does not require that states develop a coastal protection program, but it provides two specific incentives to encourage participation. First, it provides financial assistance to establish coastal management programs. Second, it assures states that federal actions in the coastal areas of participating states will be consistent with enforceable policies. Essentially, the Act vests considerable authority in the states to implement coastal management programs. In order for federal actions to occur that are not consistent with state policies, the President must determine that the actions are paramount to the interest of the United States.

As a result of the federal Coastal Zone Management Act, the State of North Carolina passed the CAMA in 1974. The CAMA established the North Carolina Coastal Resources Commission (NCCRC). NCCRC is responsible for adopting CAMA's implementing rules. In September 1978, the National Oceanic and Atmospheric Administration (NOAA) approved the North Carolina Coastal Management Program (NCCMP), which is administered by the North Carolina Department of Environment and Natural Resources (NCDENR), Division of Coastal Management (DCM). DCM works to protect, conserve, and manage North Carolina's coastal resources though an integrated program of planning, permitting, education, and research. DCM administers CAMA, the Dredge and Fill Law, and the federal CZMA in the coastal zone, using rules and policies of the NCCRC.

CAMA requires each of the 20 coastal counties in North Carolina to have a local land use plan that meets guidelines established by the NCCRC. Municipalities within coastal counties may establish land use plans independent from their respective counties. The act provides financial assistance to support coastal communities in developing their land use plans. Once a land use plan is certified by NCCRC, DCM uses the plan when making CAMA permit decisions. Proposed development must be consistent with the local land use plan, or DCM will not permit a planned development to be implemented.

In addition to certifying local land use plans, CAMA regulations also require NCCRC to identify certain areas of environmental concern (AECs) and adopt rules and policies for coastal development within those areas. AECs are broadly defined as: the estuarine system, the ocean hazard system, public water supplies, and natural and cultural resources. These are environmentally fragile and important land and water areas that are judged to be of greater-than-local significance. AECs encompass less than 3 percent of the land in the 20 coastal counties covered by CAMA. NCCRC, in cooperation with local governments in the 20-county coastal area, has developed a program of permit review and coordination within these AECs. The intent of the regulatory program is to ensure the compatibility of development with the continued productivity and value of certain critical land and water areas. Such areas—including those under State and federal jurisdiction—are subject to special management controls and development permitting procedures. In addition, a proposed development must comply with the policies and

land classifications of the local land use plans and with the local zoning ordinances, subdivision regulations, and other local development regulations to receive a permit to build in CAMA areas.

If an application for a CAMA permit is denied, or if the applicant finds the conditions on a permit unacceptable, the applicant may appeal the permit decision or petition NCCRC for a variance to undertake a project that is prohibited by CAMA or NCCRC's development standards. Applying for a variance means that the applicant recognizes the legal restrictions as valid, but requests an exception to the restrictions because of hardships resulting from unusual conditions. A permit decision must have been received before a variance can be sought. In order to apply for a variance, the applicant must file a petition for a variance with the NCDENR-DCM Director and the State Attorney General's Office on a standard form, which must be accompanied by additional information on the nature of the project and the reasons for requesting a variance. In order to be granted a variance, the applicant must show that:

- Strict application of NCCRC's development standards would result in unnecessary hardships;
- These hardships result from conditions peculiar to the property, such as its location, size or topography;
- The hardships did not result from actions taken by the petitioner; and
- The requested variance is consistent with the spirit, purpose and intent of NCCRC's development standards; will secure public safety and welfare; and will preserve substantial justice.

Dare County has substantial amounts of environmentally fragile areas, and many of these lands have been designated as AECs. The Seashore and the Refuge are protected by an AEC designation. Thus, the entire project area, with the exception of portions of Rodanthe is protected as an AEC. AECs within the project area include all estuarine waters, public trust waters, lands within 75 feet (22.9 meters) of the mean high-water line of those waters, coastal wetlands, inlet hazard areas, and ocean hazard areas.

3.1.3.2 Dare County Land Use Plan

Since the ratification of the CAMA in 1974, Dare County has been required to have a land use plan. The *Dare County Land Use Plan, 2003 Update* (Dare County, 2003) was completed and certified by the NCCRC in July 2003. The previous update was completed in 1994. The *Dare County Land Use Plan* is an evolving document that was first completed in 1976. The review process for the 2003 update included a land use plan survey, which was conducted in 2001 and is summarized in the *2001 Dare County Land Use Plan Update Issue Questionnaire Report of Findings* (Dare County, 2001). The *Dare County Land Use Plan, 2003 Update* provides a set of guidelines to manage growth and development in unincorporated Dare County over the next five years. The land use plan recognizes the priority of the transportation needs in Dare County. Accordingly, it contains specific policies for protecting NC 12 and for working in coordination with the North Carolina Department of Transportation (NCDOT) for a replacement of Bonner Bridge.

One of the goals stated in the *Dare County Land Use Plan, 2003 Update* is to develop facilities for pedestrians and bicyclists that connect its population nodes, providing for travel by means other than the automobile. The land use plan supports the development of bikeways, walkways, and greenways.

Another goal of the plan is to maintain the "coastal village" atmosphere of the County. The plan indicates that new development, particularly national retail franchises and "chains," should maintain the look and feel of the surrounding community. The plan predicts that future development will shift from new development toward redevelopment of land. It supports the re-use of historic residential structures for business or commercial purposes. The plan also predicts that the limited amount of commercial enterprises in the County will move toward serving the needs of year-round residents rather than seasonal visitors.

One of the major changes in the 2003 plan is the relaxation of wetland mitigation requirements. Because of the strict language in the 1994 plan, some public projects in Dare County—such as the new Virginia Dare Bridge—experienced permit review problems. The policy in the 2003 plan is intended to provide more flexibility so as not to preclude projects that would benefit Dare County and its citizens. The 2003 plan also supports beach nourishment to maintain the shoreline.

3.1.3.3 National Park Service Plan

The NPS's *Management Policies* (NPS, 2001) is the basic Service-wide policy document of the NPS. Adherence to these policies is mandatory unless specifically waived or modified by the Secretary of the Interior, the Assistant Secretary of the Interior, or the Director of the NPS. The policies provide guidelines for interpreting the National Park Service Organic Act (16 USC 1) and the 1978 amendment to the National Park System General Authorities Act of 1970 (16 USC 1a-1). These acts prohibit the impairment of park resources and values. *Impairment* in this context refers to an impact that, according to the NPS manager, would harm park resources or values. The resources and values affected, direct and indirect effects, cumulative effects, and the severity, duration and timing of the impact contribute to whether an impact meets this definition. The policies further state that "an impact would be less likely to constitute an impairment to the extent that it is an unavoidable result, which cannot reasonably be further mitigated, of an action necessary to preserve or restore the integrity of park resources or values."

The *General Management Plan and Amended Environmental Assessment for Cape Hatteras National Seashore* (NPS, 1984) and the *Draft Revised Statement for Management* (NPS, 1991) serve as the NPS plans for the Seashore. Completion of a new General Management Plan is scheduled for 2010 or 2011. The current two management documents provide for the preservation of the cultural resources and the flora, fauna, and natural physiographic conditions, while allowing appropriate recreational use and public access to the oceanside and soundside shores. Included in these plans are provisions for controlling off-road vehicles, providing for accessible oceanside and soundside sites, allowing natural seashore dynamics to occur, controlling exotic vegetation, preparing natural and cultural resource studies, and cooperating with state and local governments to achieve mutual planning objectives.

In 1973, the NPS—realizing the problems that the managed dune system caused the estuaries—announced a change of desire with respect to management of the Seashore. The NPS no longer attempts to stabilize the Outer Banks artificially but where possible allows natural processes to take their course. In its 1991 *Draft Revised Statement for Management*, the NPS affirmed a desire to manage the Seashore in ways "that support the natural processes of barrier island dynamics..." (NPS, 1991). The NPS's desire was affirmed in part by the USFWS's special use permit issued in 1989 for construction of the terminal groin at the north end of Hatteras Island. The permit states that if, as a result of a required shoreline monitoring program, the "NCDOT determines that the terminal groin and revetment are causing adverse shoreline erosion or migration by interrupting or otherwise affecting natural or normal sand migration, NCDOT will

either remove the structures or perform additional beach nourishment." This Final Environmental Impact Statement (FEIS) for replacing Bonner Bridge was prepared with the understanding that this long-term desire has not changed despite recent threats of ocean overwash and shoreline erosion to NC 12 within the Seashore and the NCDOT's ongoing efforts to protect and maintain NC 12.

No new Seashore facilities are planned in the project area. The Seashore's plans focus on restoration and maintenance of existing facilities. The plans also support the construction of bicycle lanes along NC 12.

The *Cape Hatteras National Seashore Long-Range Interpretive Plan* (September, 2007) provides a vision for the future of interpretation at the Seashore. The plan "confirms the foundations of the park: its purpose, significance, interpretive themes, visitor profiles, visitor experience goals, issues and influences, and existing conditions," as well as "recommends actions to be taken over the next five to seven years to improve the park's personal services program and interpretive media, and provides an achievable implementation strategy." The program includes goals related to improving personal services and visitor facilities. None of the visitor facilities referenced for improvement are in the project area.

Planning efforts ongoing in 2008 include an off-road vehicle negotiated rulemaking and management plan, a predator control program for protected species management, and a plan to relocate the Coast Guard Station and Life Saving Station on Bodie Island. Off-road vehicle management, as it relates to protected species, is currently (2008) managed under a Consent Decree (i.e., a judicial ruling that sanctions a voluntary agreement between parties in dispute) that was approved by a US District Court judge on April 30, 2008. The Consent Decree is a compromise solution between the NPS, Dare County, and other groups that wanted beach access preserved for recreational use and environmental groups that wanted beach access banned in order to preserve and protect wildlife. The Consent Decree ends the lawsuit brought by two environmental groups against the NPS in October 2007. The lawsuit challenged the failure of the NPS to have an adequate management plan in place to protect birds, sea turtles, and other natural resources from the impacts of beach driving. The Consent Decree specifies that a final long-term off-road vehicle (ORV) management plan be implemented by the NPS no later than April 1, 2011. Until the final ORV management plan is adopted, the Consent Decree requires the NPS to: take immediate actions to address declining populations of nesting shorebirds and water birds on the Seashore; provide enhanced protection to the threatened piping plover; and provide additional protections to the three species of endangered or threatened sea turtles that nest on the Seashore. It also calls for public education on beach driving and the protection of the region's natural resources while providing opportunities for ORV and pedestrian access.

3.1.3.4 Pea Island National Wildlife Refuge Comprehensive Conservation Plan

The USFWS prepared a *Comprehensive Conservation Plan* (USFWS, 2006) to guide the management of the Refuge. The plan, which was published in September 2006, outlines programs and corresponding resource needs for the proceeding 15 years, as mandated by the National Wildlife Refuge System Improvement Act of 1997. The purpose of the plan is to identify the role that the Refuge will play in support of the mission of the National Wildlife Refuge System and to provide long-term guidance to the Refuge's management programs and activities. The goals of the plan are to:

- Provide a clear statement of direction for the future management of the Refuge;

- Provide Refuge neighbors, visitors, and local, state, and federal government officials with an understanding of the USFWS's management actions on and around the Refuge;

- Ensure that the USFWS's management actions, including land protection and recreational and educational programs, are consistent with the mandates of the National Wildlife Refuge System Improvement Act of 1997;

- Ensure that the management of the Refuge is consistent with federal and state laws; and

- Provide a basis for the development of budget requests for the Refuge's operational, maintenance, and capital improvement needs.

There are several objectives for each of the five plan goals that relate to management of fish and wildlife populations, management of habitat, public use, resource protection, and Refuge administration.

Five alternatives were developed and analyzed in the plan, with public input, to meet Refuge goals and objectives. The five alternatives are:

1. Alternative 1—proposed to maintain the status quo;

2. Alternative 2—proposed moderate program increases;

3. Alternative 3—proposed optimum program increases;

4. Alternative 4—assumed that vehicular access to the Refuge on a paved road would be eliminated from the north but would be maintained from the south as far north as the Refuge's Visitor Center; and

5. Alternative 5—assumed that access to the Refuge on a paved road would be totally eliminated.

The planning team selected Alternative 2 as its preferred alternative. It advances the Refuge program considerably, and was viewed as more realistic than Alternative 3 in terms of expected staffing levels to conduct proposed programs. Alternative 2 assumes a bridge over Oregon Inlet and a maintained road in the Refuge pending NCDOT's decisions on the replacement of Bonner Bridge and the long-term maintenance of NC 12.

The general goals of the plan's preferred alternative are:

> "*FISH AND WILDLIFE POPULATIONS*: Protect, maintain, and enhance healthy and viable populations of indigenous migratory birds, wildlife, fish, and plants including federal and state threatened and endangered species.
>
> *HABITAT*: Restore, maintain, and enhance the health and biodiversity of barrier island upland and wetland habitats to ensure optimum ecological productivity.
>
> *PUBLIC USE*: Provide the public with safe, quality wildlife-dependent recreational and educational opportunities that focus on barrier island wildlife and habitats of the refuge.

Continue to participate in local efforts to sustain economic health through nature-based tourism.

RESOURCE PROTECTION: Protect refuge resources by limiting the adverse impacts of human activities and development.

ADMINISTRATION: Acquire and manage adequate funding, human resources, facilities, equipment, and infrastructure to accomplish all refuge goals."

Specific goals, objectives, and strategies are included in the plan for each of the above general goals. They reflect the Refuge's commitment to achieving: the mandates of the National Wildlife Refuge System Improvement Act of 1997; the mission of the National Wildlife Refuge System; the North American Waterfowl Management Plan; and the purpose and vision for the Refuge. Depending upon the availability of funds and staff, the Refuge intends to accomplish their goals, objectives, and strategies during the next 15 years (2021).

General management directions under the Refuge's preferred alternative include:

- Protecting, maintaining, restoring, and enhancing Refuge lands for resident wildlife, waterfowl, migratory nongame birds, and threatened and endangered species.

- Initiation of extensive wildlife and plant census and inventory activities to develop the baseline biological information needed to implement management programs on the Refuge.

- Direction of management actions towards achieving the Refuge's primary purposes: (1) preserving nesting and migratory habitat for neotropical migratory songbirds; and (2) helping to meet the habitat conservation goals of the North American Waterfowl Management Plan, as well as managing the Refuge to contribute to other national, regional, and state goals for protecting and restoring populations of wildlife.

- Implementing active habitat management through forest management and moist-soil unit management designed to provide a historically diverse complex of habitats that meets the foraging, resting, and breeding requirements for a variety of species.

- Continuing to seek acquisition of all in-holdings from willing sellers within the present acquisition boundary.

- Developing and implementing a habitat management plan designed to maintain the present spatially and specifically diverse mosaic of habitats with little negative effect to wildlife objectives.

- Providing opportunities for quality wildlife-dependent recreation activities, including maintaining the interior and exterior access roads to provide all-weather vehicular access to a broad segment of the public.

- Permitting of hiking to support wildlife-dependent recreation to the extent that these opportunities do not substantially interfere with or detract from the achievement of wildlife conservation.

- Providing wildlife observation sites and platforms; interpretive trails, boardwalks, and kiosks; and restrooms at specific sites to allow for fully accessible environmental education and interpretation programs.

- Providing for quality fishing and hunting programs, consistent with sound biological principles with sufficient focus on migratory bird needs for resting, loafing, feeding, and courting requirements, including permitting fishing along the banks of streams and ditches and from boats.

- Continue implementing an environmental education plan, incorporating an aggressive and proactive promotion of both on- and off-site programs.

Although Alternative 2 was selected as the Refuge's preferred alternative, the Refuge evaluated Alternatives 4 and 5 in the event that the NCDOT would build the Bonner Bridge replacement in the Pamlico Sound Bridge Corridor. The plan notes that the NCDOT is considering Bonner Bridge's replacement, but has not yet made a decision. The plan also notes that the "status quo" alternative in the plan should not be interpreted in any way as a statement that the USFWS prefers Bonner Bridge or NC 12 remain where they are located currently. The alternatives merely reflect planning strategies with the road and bridge located in their current positions. The plan states that if paved road access to the Refuge is altered or eliminated as a result of NCDOT's replacement of Bonner Bridge, the plan may require revision to reflect new methods of access.

3.1.4 Zoning

Dare County is responsible for zoning in the communities of Hatteras Island and other unincorporated areas of the County. The primary focus of the current zoning code is on building heights and setbacks, etc., with no specific use restriction in any particular location. The County has plans to create use-specific zoning maps for areas not zoned or minimally zoned. Currently, Rodanthe is zoned S-1; this permits all uses, including multifamily residential. The rest of the project area is not within the jurisdiction of Dare County and therefore is not zoned.

The *Dare County Land Use Plan* has a land classification system that includes six of the seven different land classifications identified in CAMA guidelines, as well as two sub-classes. Rodanthe is classified as *Limited Transition*. Limited Transition indicates that an area is suitable for lower-density development because of its geographic remoteness. Land in the project area not within Rodanthe is classified as *Conservation*. The Conservation classification is intended to provide for the effective long-term management and protection of significant, limited, or irreplaceable areas. This classification includes, but is not limited to, all CAMA AECs.

3.1.5 Coastal Barrier Resources System

The Coastal Barrier Resources Act (CBRA) withdraws federal assistance for infrastructure in areas deemed "undeveloped" in 1982. Coastal Barrier Resources System (CBRS) Unit L03 is on Hatteras Island. It is divided into two parts, one near Avon and one near Buxton. The federal government no longer can provide financial assistance for new infrastructure in CBRS areas. Specifically, the act prohibits federal expenditures for buildings, airports, roads, bridges, causeways, piers, jetties, seawalls, water supply systems, and utility lines within the CBRS.

3.1.6 Population Characteristics

Population figures for Dare County and the communities on Hatteras Island are shown in Table 3-1. Population growth in Dare County has occurred at a faster rate than the State of North Carolina's growth. According to the State Data Center, the 2010 population projection for Dare County is 36,681, which represents growth of 22.4 percent from 2000 to 2010. This projected growth rate remains slightly higher than the projected statewide growth of 17.9 percent (based on a 2010 population projection for North Carolina of 9,491,372).

Table 3-1. Permanent Population

Permanent Population	Hatteras Island	Dare County	North Carolina
1990	3,814	22,746	6,628,637
2000	4,001	29,967	8,049,313
Percentage Change	4.9%	31.7%	21.4%

Source: US Census of Population, 1990 and 2000.

Dare County has a large nighttime seasonal population that can be as high as 126,000, 4.2 times the permanent population. The daytime seasonal population can be as high as 232,000 (*Outer Banks Economic and Demographic Package*, Outer Banks Chamber of Commerce, 2003). Although the seasonal influx is highest during the summer months (June to August), more visitors are arriving as early as Easter weekend and as late as Thanksgiving weekend. Representatives of the Dare County Planning Department postulate that the growth of permanent residents and peak visitation levels in Dare County and on Hatteras Island will continue into the future.

As shown in Table 3-2, the age distribution across population cohorts generally is consistent between Hatteras Island, Dare County, and the State of North Carolina. The median age for Hatteras Island is higher than the county and state as a whole, as is the percent of persons aged 65 or above.

Table 3-2. Age Distribution

Age in Years	2000		
	Hatteras Island	Dare County	North Carolina
0 to 18	18.2%	22.4%	25.8%
19 to 64	65.3%	63.8%	62.2%
65 or above	16.6%	13.8%	12.0%
Median Age	42.9	40.4	35.3

Source: US Census of Population, 2000.

Income, poverty, and minority characteristics of the project area compared with Dare County as a whole and the State of North Carolina are discussed in Section 3.2.

3.1.7 Economics

3.1.7.1 Permanent Housing Values

The 2000 US Census found that the median permanent home value on Hatteras Island was $139,180, compared with $137,200 in Dare County as a whole and $108,300 in the State of North Carolina. The median rent paid by the permanent population was $619 per month on Hatteras Island, $638 per month in Dare County, and $548 per month in the State. These statistics indicate that the cost of housing for the permanent residents of Hatteras Island is greater than that for the state as a whole. The housing costs on Hatteras Island and in Dare County are comparable.

3.1.7.2 Labor Force

Dare County's economy has been, and continues to be, heavily dependent on travel-related industries. The largest industries in 2000 were retail trade, 23.3 percent of earnings; services, 20.2 percent; and construction, 11.5 percent. In 1990, the largest industries were services, 22.7 percent of earnings; retail trade, 22.4 percent; and construction, 17.2 percent. The fastest growing sector was finance, insurance, and real estate; it increased at an average annual rate of 14.5 percent between 1990 and 2000.

The growing dependence of Dare County on travel-related industries is further exemplified by the increasing percentage of the labor force involved in employment related to that sector. Table 3-3 highlights the county's four primary labor force distributions as compared to the state's and the nation's in 1980, 1990, and 2000. Dare County's employment is not as diversified as those of the state and the nation. It is highly dependent on jobs in these four categories, which comprised more than 75 percent of the total work force in the year 2000.

Table 3-3. Labor Force Distribution

	Dare County			North Carolina			United States		
	1980	1990	2000	1980	1990	2000	1980	1990	2000
Construction	8%	13%	11%	5%	6%	7%	5%	5%	6%
Retail Trade	27%	29%	28%	14%	16%	16%	16%	16%	16%
Financial/Insurance/ Real Estate	12%	11%	14%	6%	6%	6%	8%	8%	8%
Services	21%	23%	24%	16%	21%	27%	22%	28%	32%
TOTAL	**68%**	**76%**	**77%**	**41%**	**49%**	**56%**	**51%**	**57%**	**62%**

Source: Bureau of Economic Analysis, April 2003.

3.1.7.3 Demand for Unimproved Land

Growth in the travel-related industries has been driven by growth in the number of summer visitors, summer and vacation cottage construction, commercial growth, and new permanent residents. Commercial growth has included increases in the number of restaurants, retail stores, rental home properties, motels, and hotels. Table 3-4 uses land sales data from the Dare County Tax Department to highlight the growth in demand for (unimproved) land from 1996 to 2002.

Table 3-4. Land Sales in Dare County

	1996	1997	1998	1999	2000	2001	2002
Number of Land Parcels Sold Annually	6,175	5,333	7,163	6,028	6,442	6,514	7,478
Value of Land Sold (in 1996 thousands of dollars)	$240,617	$242,426	$416,102	$427,040	$542,345	$653,007	$1,031,535
Percent Change in Sales	N/A	0.8%	71.6%	2.6%	27.0%	20.4%	58.0%

Source: Dare County Tax Department

3.1.7.4 Dare County Economic Indicators

Table 3-5 summarizes five key current economic indicators for Dare County, including building permit values, land transfer tax, gross retail sales, gross occupancy receipts, and food/beverage sales. As shown in Table 3-5, most of these series indicate rapid current growth. In addition, there is a high degree of seasonal variation in most of these figures reflecting the area's dependence on tourism.

Table 3-5. Dare County Economic Indicators

	2003 (Total)	2004 (Total)	2003-2004 Percent Change	February 2004	August 2004
Building Permit Values	$295,600,000	$342,200,000	15.5%	$26,700,000	$18,500,000
Land Transfer Tax	$10,400,000	$14,500,000	39.4%	$700,000	$1,200,000
Gross Retail Sales	$1,258,000,000	$1,390,600,000	10.5%	$55,100,000	$238,000,000
Gross Occupancy Receipts	$256,700,000	$259,600,000	1.1%	$1,400,000	$68,600,000
Food/Beverage Sales	$153,600,000	$166,000,000	8.1%	$5,500,000	$25,900,000

Source: Outer Banks Chamber of Commerce

3.1.7.5 Dare County Tax Structure

After a property revaluation in 2005, Dare County's base real estate tax rate is 0.25 per $100 of assessed value, with additional charges for fire, sanitation, and community services. Prior to the revaluation, the rate was 0.54 per $100. Dare County's effective property tax rate (the rate of tax as a percentage of market value) is $0.36. Incorporated towns also have their own additional tax rates, as do unincorporated areas.

Other state and local taxes within Dare County include:

- 1 percent Land Transfer Tax;
- 2 percent Retail Food Sales Tax;

- 5 percent Occupancy Tax, comprised of:
  - 3 percent Room Occupancy Tax
  - 1 percent Room Occupancy and Tourism Development Tax
  - 1 percent Room Occupancy and Tourism Development Tax for Beach Nourishment;
- 1 percent Prepared Food and Beverage Tax; and
- 7 percent North Carolina State Sales Tax.

There are specific apportionment formulas for the distribution of the Occupancy Tax**.**

3.1.7.6 Hatteras Island Economy

Little formal data are available for just the Hatteras Island economy. In general, Hatteras Island is dominated by the Refuge, beach and recreational related activities, small businesses along NC 12, tourist cottages and motels, and large homes built as summer or seasonal vacation homes. There are about 64 businesses in the communities of Rodanthe, Waves, and Salvo, ranging from gas stations/convenience stores to campgrounds and realty agencies. Most of these businesses are primarily only open during the tourist months, from April to October.

According to information obtained from the Outer Banks Chamber of Commerce, about 26 percent of the housing value for Dare County is on Hatteras Island, with 29 percent of the occupancy receipts (from rental cottages and motels) also collected on Hatteras Island. In addition, it is estimated that approximately 25 percent of the total economic activity of Dare County is derived from Hatteras Island. (Personal communication, June 20, 2005, John Bone, Outer Banks Chamber of Commerce, Kill Devil Hills, NC.)

3.1.8 Community Services

3.1.8.1 Emergency Medical Service

Dare County provides emergency medical services (EMS) for Hatteras Island. The main offices are in Kill Devil Hills, with additional EMS stations in Nags Head, Southern Shores, Manteo, and Mann's Harbor. There also are EMS stations, each with two ambulances and crews, on Hatteras Island in Rodanthe and in the Buxton/Frisco area. Dare County maintains a helicopter in Manteo for transporting unstable cardiac and obstetric patients. Hatteras Island has doctor's offices in Avon and Hatteras Village that also serve as emergency clinics. Depending on the emergency and its location, ambulance destinations may be the two island emergency clinics or the Outer Banks Hospital in Kitty Hawk, which opened in March 2002. Before the new hospital opened, emergencies also were routed to hospitals in Elizabeth City, North Carolina; Norfolk, Virginia; and Chesapeake, Virginia.

3.1.8.2 Police Department

Hatteras Island is under the jurisdiction of the Dare County Sheriff's Department. The Dare County Sheriff's Department has approximately 57 deputies. The main office is in Manteo along with the county courthouse, magistrate office, and jail. In addition to the satellite offices in Kill Devil Hills and Nags Head, there also is a satellite in Hatteras Village at the southern end of Hatteras Island.

The Sheriff's Department assists the NPS officers who work along the beaches and in the national parks of Dare County. Other law enforcement officials in Dare County are officers of the North Carolina Highway Patrol, who focus their activities primarily along the roads in the unincorporated portions of the County.

3.1.8.3 Fire Service

Dare County is divided into 15 fire districts, including four serving municipalities and the Hatteras Island Rescue Squad. The districts on Hatteras Island include Rodanthe/Waves/Salvo, Chicamacomico, Frisco, Buxton, Avon, and Hatteras. All of the fire districts have signed mutual aid agreements with neighboring fire departments. Stations on Hatteras Island have between four and six officers and an average of 20 volunteer firefighters.

3.1.8.4 Schools

Public schools in Dare County are consolidated. Six separate school facilities serve the county. Cape Hatteras Elementary (grades K–5) and Cape Hatteras Secondary (grades 6–12) serve all of Hatteras Island. In 2002, Cape Hatteras Elementary had 312 students and a preferred capacity of 346 students, while Cape Hatteras Secondary had 358 students and a preferred capacity of 346 students. The total student population on Hatteras Island is expected to increase from 670 students to 710 by 2012. No school buses cross Bonner Bridge on a regularly scheduled daily route. Children do not have to leave Hatteras Island to attend school, although many extracurricular activities, particularly sports competitions, involve off-island travel.

3.1.8.5 Rodanthe-Waves-Salvo Community Center

The Rodanthe-Waves-Salvo (RWS) Community Center is on the south side of Myrna Peters Road (SR 1492) in Rodanthe, just east of the emergency ferry dock (see Figure 3-1c). The RWS Community Center is financed by property taxes collected from property owners in the Rodanthe, Waves, and Salvo communities. Dare County appoints a Board of Directors to oversee operations of the facility. Use of the facility is free to property owners in Rodanthe, Waves, and Salvo, and it is also rented to users from outside these communities (the rental fee pays for the cost of cleaning the facility). The facility is primarily used for events like church and civic association meetings, birthday parties, historical association meetings, and fundraisers. There is also a small outside basketball court that is maintained by Dare County. The Community Center's Assistant Director maintains a calendar of meetings scheduled for the facility. (Personal communication, July 13, 2005, Susan Gray, Assistant Director RWS Community Center, Rodanthe, NC.)

3.1.8.6 Water

Water consumers in Dare County receive water from the Town of Kill Devil Hills, the Town of Nags Head, the Dare County Regional Water System, or from private wells. The Cape Hatteras Water Association, established in 1965 as private and non-profit, previously supplied water for the southern communities of Hatteras Island. However, restrictive legislation hindered the association's ability to obtain sufficient freshwater supplies. The association was acquired in 1997 by the Dare County Regional Water System. The combined public water supply storage capacity for the county currently exceeds 24 million gallons (90.9 million liters).

The water supply in Rodanthe is provided by the Dare County, Rodanthe, Waves, and Salvo Reverse Osmosis Drinking Water Plant. Completed in 1996, the plant feeds approximately 22 miles (32.5 kilometers) of distribution pipe. Prior to the completion of the plant, the majority of

residents obtained their water from individual, unreliable, and untested private wells. Upon completion of the plant, a majority of the residents elected to receive their water supply from the public facility.

At the southern tip of Bodie Island, the water supply is provided by the Town of Nags Head. A water main exists near the northern termini of the replacement bridge corridor alternatives at the Oregon Inlet Marina and Fishing Center. The water main crosses NC 12 north of Oregon Inlet and provides service to the nearby Seashore campground.

3.1.8.7 Sewer Service

In Dare County, the treatment and disposal of sewage is handled by one of three methods:

1. A municipal sewage treatment plant in Manteo;

2. Septic tanks; or

3. Package sewage treatment plants.

For the unincorporated parts of Dare County (including Hatteras Island), conventional septic tanks comprise the most common method of sewage disposal.

3.1.8.8 Solid Waste Disposal

Solid waste collection from both residential and commercial properties in Dare County is handled by local governments. Dare County contracts with Kitty Hawk and Southern Shores for solid waste pick-up in these two towns. The County also provides services to the unincorporated areas, including Hatteras Island and Ocracoke Island. Dare County owns and operates transfer stations in Buxton and Manteo. In 1994, the County entered a regional solid-waste authority; all solid waste from Dare County now is transported to a regional landfill in Bertie County, North Carolina.

3.1.8.9 Power and Telephone

Bonner Bridge carries electricity and telephone cables to Hatteras Island. These cables are the sole source of service on the island. In addition to the electrical cables servicing facilities on Hatteras Island, low-voltage submarine cables service the residents of Ocracoke Island.

Sprint Communications is responsible for all telecommunication service near the project area. Facilities previously operated by Carolina Telephone and United Telephone were acquired by Sprint and are utilized as part of the active network. Both copper and fiber optic lines are buried along the shoulders of NC 12 south of Bonner Bridge. The fiber optic lines are attached to the east side of Bonner Bridge and are buried along the east side of NC 12 north of the bridge. The copper lines terminate south of Bonner Bridge.

North Carolina Power supplies electricity to the north side of Bonner Bridge, and Cape Hatteras Electric Membership Corporation supplies the south side. The portion of the existing transmission line attached to Bonner Bridge, the portion north of Oregon Inlet, and the portion between Oregon Inlet and Buxton were upgraded in 1995. They are the property of the Cape Hatteras Electric Membership Corporation. The lines attached to Bonner Bridge were upgraded to three ducts, and hung from the east side of the structure. The old lines on the west side of the structure were abandoned. Also in 1995, approximately 1,800 feet (548.6 meters) of transmission

line on Bodie Island just north of Bonner Bridge were placed underground on a new 15-foot (4.6-meter) right-of-way on the east side of NC 12. The east side of the highway was chosen to minimize interference with construction of the then-proposed replacement bridge.

A new riser/breaker station was constructed to accommodate this underground transmission line. This station serves as the location of the transfer of the Electric Membership's lines to those of North Carolina Power. This station is on the west side of NC 12, north of the marina and west of the campground. The existing riser station on the north end of Hatteras Island was rebuilt. The riser station is on the west side of NC 12, as are the above ground lines through the Refuge. (Personal communication, May 29, 2003, Jim Kinghorn, Cape Hatteras Electric Membership Corporation, Buxton, NC.)

3.1.8.10 Cable Service

Charter Communications is the primary provider of cable service technology to the Dare County coastal community. Currently, their access to Hatteras Island is limited, as Bonner Bridge cannot accommodate the additional service lines. The communication company has deemed it impractical to provide lines to the island through other means. Thus, microwave transmission and a satellite farm in Waves are used to service the communities of Hatteras Island. Currently service is provided to approximately 3,000 customers. (Personal communication, May 29, 2003, George Weaver, Charter Communications, Nags Head, NC.)

3.1.8.11 Emergency Ferry Dock

A NCDOT emergency ferry dock is in Rodanthe. Its purpose is to move people and goods between the mainland at Stumpy Point and Hatteras Island should Bonner Bridge be unavailable for use. The channel (Chicamacomico) serving the dock on Hatteras Island extends west-northwest from the dock just south of the Pamlico Sound Bridge Corridor (see Figure 2-11).

3.1.9 Oregon Inlet Users

3.1.9.1 Commercial

Commercial use of Oregon Inlet is best estimated by the NCDENR's Division of Marine Fisheries' (DMF) trip ticket program. This program, established in 1994, allows the DMF to determine how many trips are made in a specific fishery. The number of commercial boat landings (i.e., when a commercial boat loaded with fish reaches the shore or a structure attached to the shore) between fiscal years (FY) 2000 and 2003 ranged from 518 to 534 per year. In FY 1999, there were only 375 commercial boat landings, a lesser amount because of the fall hurricanes of 1999. The number of commercial vessel trips (commercial vessel leaving the dock and returning) at Oregon Inlet between FY 2000 and FY 2003 ranged between 6,769 and 7,876 per year. Only 4,482 trips were taken in 1999. These figures represent vessels licensed in North Carolina as well as transient vessels whose home ports are in other states. They also include full- and part-time commercial fishermen. Fish and shellfish harvests are described in Section 3.7.6.2.

3.1.9.2 Recreational

The recreational fleet using Oregon Inlet represents more annual trips than the commercial fleet. Vessels categorized as recreational include charter fishing boats, head-boats, and private recreational crafts that either are moored in the area or brought in from other locations.

The number of recreational vessels using Oregon Inlet varies from year to year and is difficult to determine. The 1984 US Army Corps of Engineers (USACE) economic analysis (USACE, 1984), however, did identify the local recreational fleet and attempted to determine the size of the fleet brought to the area through a recreational boating questionnaire. The data collected through that study were supplemented by the 1985 "Ship-Watch" program conducted by the USACE and by 1990 inquiries at local marinas. The 1990 study estimated that the recreational fleet utilizing Oregon Inlet is in excess of 2,200 vessels, representing approximately 34,000 vessel one-way trips per year through Oregon Inlet. More recent data are not available.

The amount of total vessel utilization of Oregon Inlet is expected to remain generally stable with only a slight annual increase as a direct result of continued growth in recreational vessel usage.

The USACE maintains a channel that passes under Bonner Bridge, a channel to the Oregon Inlet Marina and Fishing Center, and other channels for Pamlico Sound users. For the charter fishing boats and other recreational boats operating out of the fishing center, however, a natural channel known as Bridge to Old House Channel (or known more commonly as “the crack”) offers a more direct route between the fishing center and Bonner Bridge’s navigation spans (see Figure 2-11).

3.1.9.3 Vessel Size

The typical size of vessels using Oregon Inlet in the future is not expected to exceed that of the largest fishing boats or recreational vessels using Oregon Inlet today. The best available data on vessel size were provided by the US Coast Guard Station at Oregon Inlet. (Personal communication, September 24, 2003, Boatswain Mate 1 Shane Heagy, US Coast Guard.) The largest commercial or recreational vessel currently utilizing Oregon Inlet is an occasional 100-foot (30.5-meter) motor yacht. The largest commercial vessels in use in the Oregon Inlet are 80- to 85-foot (24.4- to 25.9-meter) steel haul trawlers. These vessels utilize Oregon Inlet daily over four months in the wintertime. According to US Coast Guard personnel, utilization of Oregon Inlet by vessels in excess of this size is rare because of the unpredictable channel locations and the shifting shoals. Such vessels generally are confined to dredge and construction barges.

3.1.10 Underground Storage Tanks and Hazardous Waste

A geo-environmental impact evaluation was conducted within Pamlico Sound Bridge Corridor project area in June 2003. A second impact evaluation was conducted of the project area, including the Refuge, in July 2005. A third impact evaluation was conducted in Rodanthe within the corridor for the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) in October 2007. The main purpose of these investigations was to identify properties within the project area that might contain hazardous materials and result in future environmental liability if acquired. These hazards may include, but are not limited to underground storage tanks (UST), hazardous waste sites, regulated landfills, and unregulated dumpsites. Field reconnaissance surveys were conducted in the project area in association with all three impact evaluations. In addition, file searches of appropriate environmental agencies were conducted to identify any known problem sites.

Based on searches of a geographic information systems database and the field reconnaissance surveys, no potential Resource Conservation and Recovery Act (RCRA) or Comprehensive Environmental Response and Liability Act (CERCLA) sites were identified within the project area.

On Hatteras Island at Rodanthe, there are two gas stations/convenience stores with active USTs within the project area. The North Beach Mart and Campground is on the east side of NC 12 approximately 300 feet (91.4 meters) north of Sea Haven Drive (see Figure 3-1c). The front of the canopied pump island is 47 feet (14.3 meters) from the centerline of NC 12. The October 2007 impact evaluation indicated that there are four USTs in use at this site. The current UST area is north of the store and pump island, and set back 58 feet (17.7 meters) from NC 12. The file search for this property indicated that six USTs were removed in 1992; however, the October 2007 impact evaluation stated that no monitoring wells were noted on the property, and there is no other evidence of USTs or UST removal.

The Liberty service station is the second gas station/convenience store with active USTs in Rodanthe. The Liberty service station is on the west side of NC 12 approximately 230 feet (70.1 meters) south of Sea Oats Drive (see Figure 3-1c). The front of the canopied pump islands is 45 feet (13.7 meters) from the centerline of NC 12, which is within the existing 100-foot (30.5-meter) right-of-way on this section of NC 12. The October 2007 impact evaluation indicated that there are four USTs in use at the site. The current UST area is south of the pump islands and set back 75 feet (22.9 meters) from NC 12. The file search for this property indicated that five USTs were removed in 1988 and four more tanks were removed in 1994; however, the October 2007 impact evaluation stated that no monitoring wells were noted on the property and there is no other evidence of USTs or UST removal.

A garage/auto repair business and automobile junkyard is also in the project area on Hatteras Island (see Figure 3-1c). The business is just north of the Liberty service station and behind a group of small strip shops along NC 12. According to the property owner, all USTs were removed. There is one above ground storage tank (AST) used to store waste oil on the property. The junkyard contains old automobiles, automobile parts, and boats, although junked cars were removed from a part of the area between 2003 and 2004. Minor staining of the ground has occurred from fluids leaking from the junked vehicles and parts. According to the property owner, in the past there were various other repair shops on the property, and other areas of the larger property were also used as a junkyard.

On Bodie Island, the Oregon Inlet Marina and Fishing Center has four ASTs currently in use. The ASTs are approximately 380 feet (115.8 meters) from the centerline of NC 12. According to the NCDENR's Division of Water Quality (DWQ), Groundwater Planning Unit, there was a groundwater incident reported at the Marina in 1990 (Incident No. 6046). Several monitoring wells were noted at the site, and it appears that the site is currently under remediation. None of the current tanks are within the area directly affected by the two proposed corridors.

A Preliminary Site Assessment (PSA) was conducted for the Liberty service station/convenience store, the automotive repair facility, and the automobile junkyard for the Pamlico Sound Bridge Corridor (Catlin Engineers and Scientists, December 2003). The PSA included soil and groundwater sampling. The testing of the soil samples did not reveal the presence of any compound in concentrations above the lowest corresponding Maximum Soil Concentration allowed by the NCDENR. Minor soil contamination from Diesel Range Organics (diesel fuel and associated compounds) was found within the area directly affected by the two Rodanthe Terminus Options for the Pamlico Sound Bridge Corridor defined in Section 2.9.4. The contaminated soil samples were taken from two borings in the northern part of the junkyard. However, at 11 and 12 parts per million (ppm), the contamination is below the regulatory limit for surface releases of 40 ppm. Groundwater contamination was not detected in excess of the laboratory reporting (detection) limits.

3.1.11 Farmland

The US Soil Conservation Service (now the US Natural Resources Conservation Service [NRCS]), in a June 19, 1990, letter (see Appendix A), determined that there are no important farmland soils in the project area. The NRCS re-confirmed this determination on May 20, 2003. (Personal communication, Mike Hinton, NRCS.)

3.2 Environmental Justice

3.2.1 Executive Order 12898

Executive Order 12898, issued in February 1994, requires federal agencies to identify and address any disproportionate health or environmental impacts of their programs, policies, and activities on minority or low-income communities. It also calls for the meaningful involvement of these populations in project planning.

Minority is defined as Black, American Indian or Alaskan Native, Hispanic, or Asian-American populations. *Low-income* is defined as a household income at or below the US Department of Health and Human Services poverty guidelines (Federal Highway Administration [FHWA], December 1998). A minority population or a low-income population is any readily identifiable group of minority or low-income persons who live in geographic proximity, and (if circumstances warrant) geographically dispersed/transient persons who would be similarly affected by a proposed FHWA program, policy, or activity.

3.2.2 Concentrations of Minority and Low-Income Populations

Block group data from the 2000 US Census were used to help identify concentrations of minority and low-income populations in the project area. Table 3-6 shows racial and poverty characteristics in the project area (Rodanthe/Waves/Salvo block group), Hatteras Island, Dare County, and the State of North Carolina. Minority and low-income households make up a smaller proportion of the population on Hatteras Island than in Dare County and the State of North Carolina. In the Rodanthe/Waves/Salvo area, minority and low-income households make up a larger part of the population than Hatteras Island as a whole and, in the case of low-income households, a larger part of the population than Dare County as a whole. During field surveys in the project area and interviews with county officials, it was concluded that low-income households most likely are concentrated in several mobile home and trailer parks in the Rodanthe/Waves/Salvo area. One such area is east of NC 12 in the project area and is shown in Figure 3-1c. No particular minority neighborhoods were identified.

3.3 Visual Characteristics

The project area can be divided into three landscape units or geographic sections for analysis of both existing visual character and potential visual impacts resulting from the proposed project. These geographic sections are the Rodanthe area, the Pea Island National Wildlife Refuge area, and the Oregon Inlet area. The three units are described below. For each unit, existing visual character, visual quality, visually sensitive resources, and viewers are described.

Table 3-6. Racial and Poverty Characteristics (Percent of Population), 2000

	Rodanthe/ Waves/ Salvo		Hatteras Island		Dare County		North Carolina	
Racial Characteristics								
Total Population	1,600		4,001		29,967		8,049,313	
White	1,545	96.5%	3,918	97.8%	28,393	94.7%	5,804,656	72.1%
Black	3	0.2%	7	0.2%	797	2.7%	1,737,545	21.6%
Other Racial Minorities	52	3.3%	76	2.0%	777	2.6%	507,112	6.3%
Hispanic	14	0.9%	31	0.7%	666	2.2%	378,963	4.7%
Total Minority[1]	62	3.9%	100	2.5%	1,939	6.5%	2,402,158	29.8%
Percent Below the Poverty Level								
	185	11.1%	296	7.5%	2,381	8.0%	958,667	12.3%

[1] Total minority is the sum of all persons other than white-non Hispanic.
Source: US Census of Population, 2000.

3.3.1 Rodanthe

3.3.1.1 Visual Character

The project area includes a northern area of Rodanthe (see photograph 1 in Figure 3-2). This area is characterized by rural coastal development that is a mixture of housing types and styles and small business commercial development. Residential development includes older one- and two-story single-family residences, trailers, and newer multi-story large beach homes.

Commercial developments are typical in appearance of the type and size found in small coastal towns. Businesses include the Liberty service station, an auto repair shop with a used car storage area, and a gift shop. An auto junkyard is between the businesses along NC 12 and Pamlico Sound. NC 12 provides the main access to the community, with east-west side streets providing access to residences on both ocean and sound sides. Homes and businesses typically have maintained grass yards. Closer to the sound, vegetation progresses generally from shrub thicket to low marsh grasses. The terrain is generally flat. Panoramic views of Pamlico Sound can be seen from the shoreline. The view is of the open water with no land visible when looking straight out into Pamlico Sound (see photograph 2 in Figure 3-2).

3.3.1.2 Visual Quality

The view of Pamlico Sound conveys visual excellence. Although other views in this portion of the project area generally are aesthetically pleasing, the components of those parts of the existing landscape do not combine to create striking characteristics. There are no officially designated scenic areas to be protected in this area.

PHOTO 2: Pamlico Sound viewed from Rodanthe

PHOTO 3: Bonner Bridge viewed from Hatteras Island near the Terminal Groin

VISUAL CHARACTERISTICS

Figure 3-2

3.3.1.3 Visually Sensitive Resources

The Chicamacomico Life Saving Station in Rodanthe is on the NRHP. This resource has views of NC 12 and the other land uses along both NC 12 and the sound from its upper stories. Visually sensitive resources are the homes in the area, particularly those that line Pamlico Sound.

3.3.1.4 Viewers

Viewers of Pamlico Sound in this part of the project area are persons in private homes lining the sound, as well as those with views from upper stories further away from the sound. Viewers also include boaters and sailboarders that recreate in this area of Pamlico Sound. Pamlico Sound generally is not visible from NC 12 because of buildings or vegetation that impair views.

3.3.2 Pea Island National Wildlife Refuge

3.3.2.1 Visual Character

Views in the Refuge have a generally consistent character, which is mostly of natural features with expansive wetlands to the west towards Pamlico Sound and of vegetated dunes to the east towards the Atlantic Ocean. Man-made features include Bonner Bridge, three freshwater ponds, the dunes between NC 12 and the ocean, and visitor and Refuge facilities. One enters the Refuge from the south via NC 12.

Because of the flat terrain to the west of the ocean-side dunes throughout the Refuge, multi-story houses in Rodanthe (in particular within the Mirlo Beach subdivision immediately adjacent to the southern Refuge boundary) are visible from a long distance away to southbound motorists on NC 12 within the Refuge.

In the southern part of the Refuge, the land is generally flat on the west side of NC 12, with small brush and some views of the backwater creeks that wind between the smaller islands between Pamlico Sound and Hatteras Island. Pamlico Sound is seldom visible from NC 12 in the Refuge. The Atlantic Ocean also is not visible in most places from NC 12 because of dunes.

Continuing north, a boat launch is located west of NC 12 (see Figure 3-1b). Here an abandoned wooden bridge over the creek is visible. There is a paved parking lot at the boat launch. The next feature is a paved parking lot with an information kiosk on the east side of NC 12. Just south of South Pond and east of NC 12 is the Refuge's headquarters, which includes four buildings.

In the midst of the Refuge are the three freshwater ponds (South Pond, New Field Pond, and North Pond) that are immediately west of NC 12 for approximately 4 miles (6.4 kilometers). North Pond has wildlife viewing/hiking trails at both its southern and northern ends. The Refuge Visitor Center is at the southern end of North Pond. The southern trail (North Pond Wildlife Trail) is popular with birders and includes raised observation platforms with spotting scopes. The other two ponds are closed to public entry, but are visible from NC 12 in places.

Most of the area east of NC 12 is covered with vegetation. There are, however, three locations within the Refuge (the Rodanthe 'S' Curves, the Sandbag Area, and the Canal Zone hot spots described in Section 1.1.3) where portions of the dunes were reconstructed, so they are not completely covered with vegetation. In these locations, the only features between NC 12 and the ocean are the dunes and the sandy beach. In addition, the view from NC 12 changes within the hot spot areas, particularly the Canal Zone hot spot, because the dunes are much closer to NC 12.

The northern Refuge exit is via Oregon Inlet and Bonner Bridge. The character of the Refuge in this area is described below in Section 3.3.3.

3.3.2.2 Visual Quality

The components of the existing landscape within the Refuge combine to create striking characteristics that convey visual excellence. The northern end of Hatteras Island between Oregon Inlet and Rodanthe is designated as a National Wildlife Refuge with its associated land use and user activities. NC 12 is also designated as a Scenic Byway by the NCDOT through the entire Refuge. As stated previously, the undeveloped and protected character of the area makes it rare along the eastern US seaboard in terms of views and a setting for recreational activities.

3.3.2.3 Visually Sensitive Resources

The entire Refuge is a visually sensitive resource from the perspectives of its natural character, its uniqueness as an undeveloped barrier island, the objectives of its viewers (see Section 3.3.2.4), and the designation of NC 12 through the Refuge as a Scenic Byway by the NCDOT. The Refuge was found to be eligible for the NRHP under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history (see Section 3.4.1.1). A letter dated September 17, 2003 from the North Carolina SHPO that affirms this finding is contained in Appendix A.

3.3.2.4 Viewers

Viewers include visitors stopping and participating in recreational activities within the Refuge, as well as the users of NC 12 noted in Section 3.3.3.4. The major recreational activities within the Refuge are birding, fishing (from both the catwalks and surf fishing), surfing, boating, and beach usage activities such as sunbathing and walking. Birders, in particular, frequently view NC 12 while conducting their activities. For example, the most popular locations for birding are the trails around North Pond, and NC 12 is visible from many locations on these trails. Birders also use many of the other parking lots and information kiosks along NC 12, or just pull to the side of the road when they see birds. Thus, NC 12 is generally visible while they are conducting their activities. Individuals participating in activities on the beach generally do not have views of NC 12, but only of the dunes that lie between NC 12 and the Atlantic Ocean. The longest distance views in the Refuge are generally from the top of these dunes.

3.3.3 Oregon Inlet

3.3.3.1 Visual Character

In general, the northern end of Hatteras Island and southern end of Bodie Island have a low vertical profile with slightly rolling terrain and scattered vegetation. Sandy beaches are along the oceanfront and inlet side of the islands. Salt marsh and mudflats are on the soundside of the islands. The middle portions of the islands in the vicinity of Oregon Inlet are vegetated sparsely with dune grasses, yaupon, and myrtle. Other than the marsh on the soundside of the islands and the general undeveloped character of the islands, there are no unique physical features related to landform or vegetation. Manmade vertical elements are present on both the Hatteras Island and Bodie Island sides of Oregon Inlet (see photograph 3 in Figure 3-2).

On the Hatteras Island side of Oregon Inlet, a public-use parking lot is on the east side of NC 12. The terminal groin and the top of the (former) US Coast Guard Station also are visible. On Bodie Island, there is a campground on the east side of NC 12. The US Coast Guard Station, a large

radio tower, and Oregon Inlet Marina are on the west side of NC 12. Other manmade features associated with the marina include a parking lot, a pier, and a stone revetment. The Bonner Bridge structure is a prominent visual feature on both sides of Oregon Inlet. The manmade features contrast with the natural characteristics of the island. Salt marsh and mudflats are on the soundside of the islands with emergent wetland vegetation such as needlerush and smooth cordgrass found there. The terrain generally is flat with some dunes bordering the beach area. Low shrubs and grasses are more prevalent further inland.

3.3.3.2 Visual Quality

The components of the existing landscape around Oregon Inlet combine to create striking characteristics that convey visual excellence. NC 12 is designated as a Scenic Byway by the NCDOT between the community of Ocracoke on Ocracoke Island and Whalebone Junction on Bodie Island. The most significant aspect of the area is its designation as a National Seashore and, on Hatteras Island, a National Wildlife Refuge with its associated land use and user activities. The undeveloped and protected character of the area makes it rare along the eastern US seaboard in terms of a setting for recreation activities such as surf fishing, bird watching, and shell collecting.

3.3.3.3 Visually Sensitive Resources

The (former) US Coast Guard Station on Hatteras Island is on the NRHP. Visually sensitive resources are the marina and the campground on the Bodie Island side of Oregon Inlet.

3.3.3.4 Viewers

Groups with a view from the road are primarily the highway users crossing Bonner Bridge, including residents of Hatteras Island and other residents of Dare County who travel the road to work and for local or regional trips. Another large group of users with a view from the road is comprised of tourists traveling to recreational opportunities in the area. Existing (2002) annual average daily traffic for NC 12 in this area is 5,400 vehicles per day (vpd), which rises to 10,900 vpd on the average summer weekend day. Groups that view NC 12 and Bonner Bridge are boaters, campers, people fishing along Oregon Inlet beaches and from the catwalks on Bonner Bridge, and US Coast Guard Station and Oregon Inlet Marina users.

3.4 Cultural Resources

Section 106 of the National Historic Preservation Act of 1966 as amended (16 USC 470f) affords consideration of those properties that are listed or eligible for listing on the NRHP.

In addition, Section 4(f) of the Department of Transportation Act of 1966, as amended (49 USC 303), states that the US Department of Transportation may not approve the use of land from a significant publicly owned park, recreation area, or wildlife and waterfowl refuge, or any significant historic site, unless a determination is made that the project will have a de minimis impact or unless a determination is made that:

- There is no feasible and prudent alternative to the use of land from the property; and
- The action includes all possible planning to minimize harm to the property resulting from such use.

In accordance with the requirements of Section 4(f), Section 106, and the National Environmental Policy Act (NEPA), surveys were conducted to identify the cultural resources in the project area.

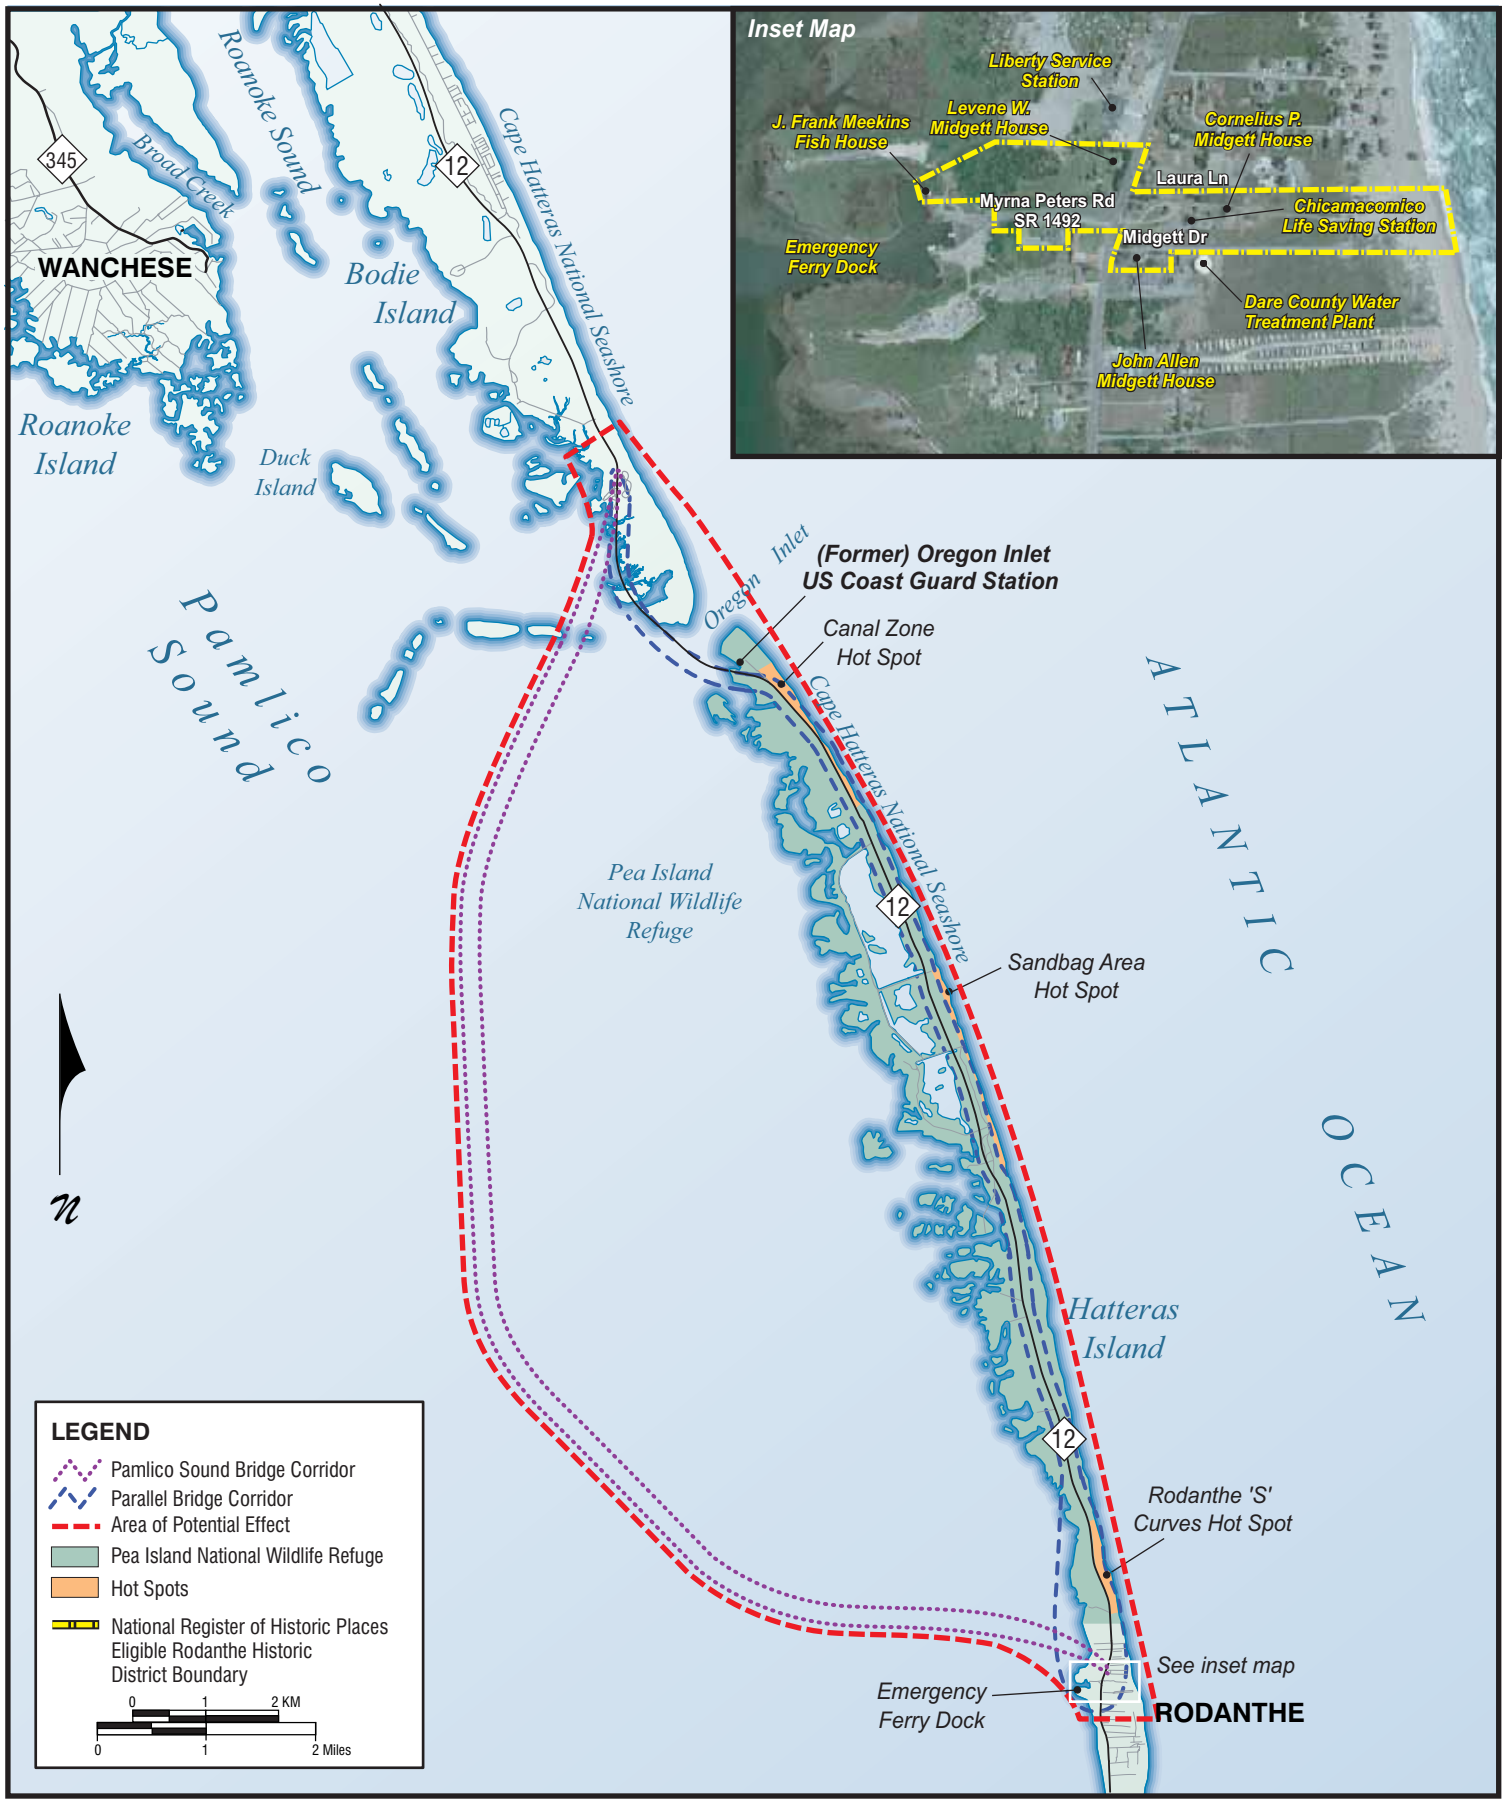
3.4.1 Architectural and Landscape Resources

A survey was conducted in order to identify historic architectural and other historic resources within the area of potential effects (APE). The APE included the area surrounding the northern terminus of Bonner Bridge and Hatteras Island from Oregon Inlet to Rodanthe. The findings of the surveys are contained in the following reports:

- *Historic Structures Survey and Evaluation Report - Bonner Bridge* (Architectural Conservation Associates, September 1990);
- *Phase II Architectural Survey Report of Pea Island National Wildlife Refuge* (Mattson, Alexander and Associates, Inc., July 2003);
- *Phase II Historic Architectural Survey Report, Herbert C. Bonner Bridge Replacement Project* (Mattson, Alexander and Associates, Inc., August 2003); and
- *Addendum to Phase II Historic Architectural Survey Report, Herbert C. Bonner Bridge Replacement Project* (URS Corporation, April 2006).

The methodology for the survey consisted of background research into the historical and architectural development of the area and a field survey of the APE. All structures 50 years of age and older were photographed, mapped, surveyed, and evaluated for NRHP-eligibility.

Four resources or resource areas within the APE were identified as either listed on or eligible for inclusion in the NRHP:



1. Pea Island National Wildlife Refuge (determined eligible);
2. The (former) Oregon Inlet US Coast Guard Station building (NRHP listed) at the northern end of Hatteras Island;
3. Rodanthe Historic District (determined eligible) at the southern end of the project area; and
4. The Chicamacomico Life Saving Station (NRHP listed), which stands within the Rodanthe Historic District.

The four historic resources also are Section 4(f) resources. (See the introduction to Chapter 5 for a definition of Section 4(f) resources.)

These resources and the project's APE are shown in Figure 3-3. The APE also encompasses a part of Pamlico Sound because the potential exists for the bridge replacement project to affect shipwreck sites (see Section 3.4.2.2.) The following sections describe the four historic resources.

3.4.1.1 Pea Island National Wildlife Refuge

The federal government established the Pea Island National Wildlife Refuge in 1938 within the Cape Hatteras National Seashore. A survey was conducted to evaluate the historical significance of the Refuge. The Refuge was found to be eligible for the NRHP. It is eligible under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history. The Refuge is an outstanding example of the national wildlife refuges that arose during the early twentieth century.

HISTORIC RESOURCES

Figure 3-3

With its manmade dikes and dunes, the Refuge also illustrates the efforts of the Civilian Conservation Corps (CCC) on the Outer Banks to protect and revitalize natural resources. The US Congress established the CCC in 1933 during the Great Depression to employ young men in the conservation and development of natural resources. A letter dated September 17, 2003 from the North Carolina State Historic Preservation Officer (SHPO) that affirms the above finding is contained in Appendix A.

3.4.1.2 (Former) Oregon Inlet US Coast Guard Station

The (former) Oregon Inlet US Coast Guard Station at the northern end of Hatteras Island is listed in the NRHP. In the nineteenth century, the US Life Saving Service established life saving stations every 6 to 8 miles (10 to 13 kilometers) along the Outer Banks. Small settlements for the life saving crews and their families grew up around the stations. The Oregon Inlet Station—as it was constructed in 1898—was similar, but not identical, to other stations built along the Outer Banks during that period.

The US Coast Guard no longer uses the structure and does not plan to return to it. The State of North Carolina owns the building and the surrounding 10 acres (4.0 hectares), and the North Carolina Aquarium Society oversees its operations and maintenance.

3.4.1.3 Chicamacomico Life Saving Station and Rodanthe Historic District

In 2003, a Phase II Historic Architectural Survey was conducted in the southern portion of the Bonner Bridge study area. In this report, eight resources (six contributing and two non-contributing) were identified as being at least 50 years of age near the Rodanthe terminus. Among those properties were five houses dating from ca.1900 to ca.1950 and the Chicamacomico Life Saving Station, which was listed in the NRHP in 1976. The cluster of houses and outbuildings that surround the life saving station are eligible for the NRHP as the Rodanthe Historic District. The district is defined by the tax parcels on which the houses and the life saving station are situated.

An Addendum to the Phase II Historic Architectural Survey was completed in April 2006, after it was determined that one of the recommended contributing resources had been moved since the completion of the initial report. In this addendum, NCDOT recommended altering the boundaries of the district by truncating the southern boundary and extending the western boundary. The revised Rodanthe Historic District encompasses approximately 17.1 acres (6.9 hectares) in Dare County. The following six buildings and associated resources were included in the district: the Levene W. (or Levine) Midgett House; the J. Frank Meekins Fish House; the (former) Rodanthe School (non-contributing); the Chicamacomico Life Saving Station; the Cornelius P. Midgett (or Payne) House, on its new site minus its boathouse and cemetery; and the John Allen Midgett House. The components of the district generally line the east and west sides of NC 12, in the Myrna Peters Road and Midgett Drive area. The revised Rodanthe Historic District is shown in Figure 3-3.

The Rodanthe Historic District is eligible for the NRHP under Criterion A for social history. The district of well-preserved dwellings, for the fishermen and merchants of Rodanthe, and fish house clustered around the Chicamacomico Life Saving Station is a rare survivor in Dare County. The metamorphosis of Dare County from an area of small, largely isolated, fishing villages to a tourist destination of international renown has almost completely eliminated any vestige of life on the Outer Banks before the late twentieth century. The string of early twentieth century houses, the life saving station at Rodanthe, and the fish house on Rodanthe harbor, are rare illustrations of life in the pre-tourism age of the mid-twentieth to late-twentieth century. The Rodanthe Historic District is also eligible under Criterion C for architecture.

The Chicamacomico Life Saving Station is illustrative of a property type unique to the Outer Banks. Listed in the NRHP, Chicamacomico is the most complete of any of the life saving stations built along the North Carolina barrier islands. In addition to its original 1874 board-and-batten station and 1911 shingle-style facility, Chicamacomico contains a detached, frame kitchen, cisterns, a flag tower, and several frame boathouses, all of which are well-preserved. Surrounding the life saving station are several houses, including the Cornelius P. Midgett House which was recently moved to the Chicamacomico Life Saving Station site, that illustrate both the persistence of traditional domestic forms in Dare County and the introduction of nationally popular designs during the early twentieth century. The station is operated as a museum. It is open from mid-April through November, though the operational months may be extended in the near future (personal communication, December 12, 2006, Linda Molloy). The number of annual visitors is approximately 10,000. According to Linda Malloy, Site Operations Manager, there was a slight drop in visitation from 2004 to 2006. Future plans for the station include: restoration of the 1874 station house; construction of a museum building to house the growing collections; continued research; expansion of the programming, living history displays, and physical facilities; and creation of two separate historic districts on site.

At the north end of the district, across NC 12 from the station, is the Levene W. Midgett House. This home was built for a member of a locally prominent family and the last keeper of the station. The Levene W. Midgett House has changed little since the 1950's or earlier. In addition to the house, the associated boathouse and storage shed also contribute to the district. A third outbuilding, modern or thoroughly reworked and raised on piers, does not contribute to the district.

The Cornelius P. Midgett House stood, largely unaltered until the past year or two, on a long road-to-sea lot south of its current location. It is now within the Chicamacomico Life Saving Station complex. The house was moved in its entirety but continues to retain its architectural integrity.

The appearance of the John Allen Midgett House has changed little since the 1950's or earlier. Immediately to the house's south rises the modern and noncontributing county desalinization facility, which provides an appropriate southern boundary for the district.

Although the siding on the original building of the J. Frank Meekins Fish House has suffered through the years, and a less than 50-year-old addition was added on one side, it retains sufficient integrity and significance to be a contributing resource within the district. Because of its significance as a rare, small-scale fish house, it is considered to be a particularly important component of the district. It appears to still be used as a staging area for fishing, although not as a commercial fish house.

All of the homes and the J. Frank Meekins Fish House are privately owned. The Chicamacomico Life Saving Station is owned by the Chicamacomico Historical Association.

The principal access for most of these resources is NC 12. The J. Frank Meekins Fish House is reached from Myrna Peters Road, which intersects with NC 12. There are no sidewalks on either NC 12 or Myrna Peters Road. Other than those noted for the Chicamacomico Life Saving Station, no improvement plans are known.

A letter dated December 5, 2006 from the North Carolina SHPO that affirms the above NRHP-eligibility finding is in Appendix A.

3.4.2 Archaeological Resources

The North Carolina Office of State Archaeology site files contain no record of terrestrial or submerged cultural resources in the Bonner Bridge project area and the associated APE. The environment of the Outer Banks provides little of the stability necessary for good terrestrial archaeological preservation. As such, archaeological studies in the project area focused on the potential for shipwrecks in Oregon Inlet and Pamlico Sound.

3.4.2.1 Likelihood of Sites Related to Human Habitation

The North Carolina Outer Banks represent one of the most dynamic environments on the Atlantic seaboard. The current barrier island complex is a relatively recent feature and a variety of estimates confirm that it has been constantly migrating in a westerly direction. Inlets that bisect the Outer Banks also are extremely dynamic and remain in an almost constant state of flux. Archaeologists generally agree that the Outer Banks' environment has a profound impact on both human habitation (as noted above) and the project area's potential for well-preserved archaeological resources (Thompson and Gardner, 1979 and NCDOT, 1989).

The environment of the Outer Banks provides little of the stability necessary for good archaeological preservation. In a dynamic environment characterized by dramatic migration, the processes of erosion and accretion prove highly destructive. Fragile prehistoric and historic period terrestrial sites have little chance of survival. The migratory nature of the Outer Banks can preclude finding Archaic or earlier sites because of the extent of changes in the land forms. In more recent times, the migratory processes associated with Outer Banks inlets can be equally destructive.

In 1991, a background archaeological survey was conducted in the Bonner Bridge area. The results of this research are documented in *Historical and Cartographic Research to Identify and Assess the Potential for Cultural Resources in the Proposed Corridor for a Replacement Bridge on NC 12 Across Oregon Inlet, Dare County, North Carolina* (Watts, 1992). This technical memorandum was reviewed by the SHPO's staff, which concurred with its recommendation that significant archaeological properties are unlikely to be found in the Oregon Inlet area (see March 27, 1992 letter in Appendix A). The North Carolina Division of Archives and History archaeological site files contain no record of terrestrial cultural resources in the Bonner Bridge area.

In 2005, the NCDOT conducted background research to evaluate the potential for terrestrial archaeological resources in the Parallel Bridge Corridor through the Refuge. A review of the files at the North Carolina Office of State Archaeology and the results of past archaeological investigations within the Refuge led the NCDOT to conclude that the potential for significant archaeological properties in the Refuge was low. The SHPO concurred that no additional archaeological work is warranted because the potential for archaeological resources eligible for the NRHP in the Refuge is minimal (see June 21, 2005 letter in Appendix A).

3.4.2.2 Likelihood of Shipwreck Sites

Historical research indicates that the project area lies in a location with an active maritime history. The examination of secondary source material (e.g., Angley, 1985; Stick, 1952, 1958; Dames and Moore, 1979; Watts, 1992; Krivor, 2003) and the site files of the North Carolina Division of Archives and History, Underwater Archaeology Branch documented the loss of approximately 96 vessels in the general vicinity of Oregon Inlet and an additional 79 vessels within Pamlico Sound. The types of wrecked vessels include those involved in various pursuits such as trade, warfare, and fishing. The majority of the documented wrecked vessels are

schooners. Other vessel types identified include barks, brigs, and steamers. While the wrecks chronologically span the entire period of historical activity along the North Carolina coast, from 1586 until 1982, documentation indicates that vessel traffic through Oregon Inlet was heaviest in the nineteenth century, with traffic during earlier periods slight in comparison (Dames and Moore, 1979; Angley, 1985; Watts, 1992; Krivor, 2003). However, reviews of the state site files within the North Carolina Office of State Archaeology, Department of Cultural Resources, identified no known archaeological sites within the project corridors; therefore, no known archaeological sites would be affected within the project area.

The project area is dynamic. Shipwreck research on the beach and in other North Carolina inlets has found, however, that both shipwreck vessel structure and an associated archaeological record warranting NRHP eligibility can survive in such an environment.

Historic maps identify four wrecks in proximity to the project area. Three of the wrecks plotted on an 1849 US Coast Guard Survey Map are likely well north of the project area because of the southerly migration of Oregon Inlet since its formation in 1846. The fourth wreck, plotted on National Oceanic and Atmospheric Administration Navigation Chart No. 12204 (1975), appears to be the remains of an iron-hulled barge that washed ashore in the early 1970s. This wreck site is in Pamlico Sound immediately west of Rodanthe (just north of the emergency ferry dock). It is a modern vessel and is not a significant submerged cultural resource. An early twentieth-century windmill also was identified during a review of historic cartographic maps; however, the windmill site is outside of the project area.

Dredging has occurred in the Oregon Inlet area. Channel dredging has occurred through the navigation zone of Bonner Bridge, in a corridor approximately 1,000 feet (304.8 meters) to the east of Bonner Bridge and in a corridor parallel to and west of Bonner Bridge. The dredging parallel to Bonner Bridge occurred during construction of the bridge. The inlet bottom was dredged where the water was less than 10 feet (3 meters) deep. This dredging occurred in an area approximately 150 feet (45.7 meters) wide and extending the full length of the bridge, except in the area of the current navigation span and several spans to the south. Dredging would have disturbed, damaged, or destroyed shipwreck resources unless scour associated with inlet movement re-deposited vessel remains at depths below the limits of dredging.

The potential for significant submerged cultural resources within Pamlico Sound Corridor area was assessed using criteria set forth by the Division of Archives and History, Underwater Archaeology Branch. The potential for wrecks within the vicinity of Oregon Inlet is moderate to high; the probability for historic vessel remains within the project area south of Oregon Inlet is moderate.

Surveys in the Parallel Bridge Corridor at Oregon Inlet

A magnetometer survey (Dames and Moore, 1979) of the Oregon Inlet navigation channel revealed several anomalies. However, no ground truthing of the Dames and Moore targets has been done. Background research revealed no known shipwrecks; however, NCDOT, FHWA, and representatives of the SHPO worked cooperatively to develop a scope of work for a remote sensing survey for underwater resources in the area that would likely be disturbed by the potential construction of an Oregon Inlet bridge in the Parallel Bridge Corridor. The survey was conducted in February 1993, excluding those areas that have been dredged in the past. The results of the remote sensing survey revealed 41 anomalies, of which three were considered high priority (two near the northern end of Bonner Bridge, and one near the southern end of Bonner Bridge), requiring investigations if not avoided. The SHPO concurred with this assessment (see May 23, 1993 letter in Appendix A). In October 1995, an underwater investigation was conducted. A brief magnetometer survey was conducted to confirm and refine each location. Visual

inspections were conducted and the anomalies in the northern area were investigated using sub-bottom probes. This investigation revealed that the source objects for the anomalies of the two clusters at the north end of the bridge either lie more than 10 feet (3 meters) below bottom or were too small to be located within the patterns of sub-bottom probing. It is, therefore, reasonable to conclude that no substantial shipwreck remains exist within 10 feet (3 meters) of the bottom in this area. The anomaly cluster at the south end of the bridge consists of three anomalies. A pipeline discovered during the diving investigation has characteristics indicating modern origin and, apparently, is the source object for two of the three anomalies. The third anomaly, indicative of an isolated single-source object, has significantly reduced potential for representing a shipwreck. Based on the results of this investigation, it is concluded that no shipwrecks exist in this area. The SHPO concurred with this finding in a letter dated June 5, 1996 (see Appendix A).

Surveys in the Pamlico Sound Bridge Corridor

The North Carolina Office of State Archaeology concurred with the results of a historical background investigation conducted for the Pamlico Sound Bridge Corridor in a letter dated July 25, 2003 (see Appendix A). Based on the results of the background investigation, the NCDOT conducted remote sensing surveys and diver investigations of the Pamlico Sound Bridge Corridor to determine if significant shipwrecks lie within the corridor. None was found. In the portion of the project area immediately west of Bodie Island, anomalies identified by remote sensing (magnetic signatures of debris revealed by a magnetometer) were found buried in the sand. Probing with a 10-foot-long (3-meter-long) hydro probe did not identify the source of the anomalies. Remote sensing data, however, suggests that the anomalies are modern debris associated with Bonner Bridge construction (Krivor, 2004). A letter from the SHPO concurring with these results is included in Appendix A.

3.5 Parks and Recreation/Wildlife Refuges

There are two publicly owned recreation areas within the Bonner Bridge Replacement project area: the Cape Hatteras National Seashore and the Pea Island National Wildlife Refuge. Seashore and Refuge lands and the waters of the Atlantic Ocean and Pamlico Sound that border the Seashore, the Refuge, and Hatteras Island as a whole are used for a variety of recreational activities. Activities within the project area include:

- Surf fishing off Atlantic Ocean beaches within the Refuge and Seashore;
- Fishing from the catwalks on the south end of Bonner Bridge;
- Surfing in the Atlantic Ocean;
- Wind-boarding (windsurfing) and kite surfing in Pamlico Sound;
- Walking along the beach;
- Birding and hiking on wildlife trails;
- Cycling along NC 12; and
- Visiting the Refuge Visitor Center.

The importance to the tourist economy of the recreational activities within the Seashore and the Refuge and along the Atlantic Ocean beachfront and in Pamlico Sound was emphasized on numerous occasions at the project's Citizens Informational Workshops, at meetings with Dare County officials, and interviews conducted during the community data-gathering process.

Except in the bulk of Pamlico Sound and in the community of Rodanthe, the project area is wholly within the Seashore or both the Seashore and the Refuge. Per Section 4(f) of the Department of Transportation Act of 1966, lands from parks and wildlife refuges cannot be used for federally sponsored transportation projects unless a determination is made that the project will have a *de minimis* impact or unless a determination is made that:

- There is no feasible and prudent alternative to the use of land from the property; and
- The action includes all possible planning to minimize harm to the property resulting from such use.

All the detailed study alternatives (including the Preferred Alternative) would use land from the Seashore. Because the Preferred Alternative would use land from the Seashore, a Final Section 4(f) Evaluation for the proposed project is contained in Chapter 5. The Seashore and the Refuge are described in the following sections.

3.5.1 Cape Hatteras National Seashore

The Cape Hatteras National Seashore in Dare and Hyde counties stretches north to south across three islands (see Figure 5-1):

- Bodie Island, from Whalebone south except along ocean beach, where Seashore lands begin about 5 miles (8 kilometers) south of Whalebone;
- Hatteras Island, the entire island except for privately held lands at the communities of Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, and Hatteras; and
- Ocracoke Island, the entire island except for privately held lands at the community of Ocracoke.

These barrier islands have a wealth of sand dunes (natural and man-made), marshes, and woodlands. The creation of the Seashore was authorized by Congress in 1937; 21 years later the final parcels were acquired and the Seashore was dedicated. The Seashore has contributed to the area's increase in tourism. It was the first in a series of national seashores established to preserve significant segments of unspoiled barrier islands along the Atlantic and Gulf coasts for the benefit and enjoyment of the people. The Seashore covers 30,319 acres (12,275 hectares) and stretches along 72 miles (115 kilometers) of open, virtually unspoiled beach and scenic drive. The State of North Carolina donated approximately 10,000 acres of the Seashore's land.

The Seashore is a publicly owned park and recreation area that is owned by the federal government and administered by the NPS. At the south end of Bodie Island, the Seashore boundary follows the mean low water mark along the Atlantic Ocean side. On the Pamlico Sound side, the boundary follows the shoreline until it reaches Oregon Inlet. The Seashore boundary on Hatteras Island, between Oregon Inlet and Rodanthe, extends to the mean low water mark along the ocean-side and extends 150 feet (45.7 meters) from the shoreline into Pamlico

Sound on the west side. Figure 5-3 shows the Seashore boundary in the vicinity of Oregon Inlet. The boundary does not follow the shoreline in the Oregon Inlet area because it was based on the shoreline location in the 1950s. The NPS and the USFWS share management duties where the boundaries of the Seashore overlap with those of the Refuge at the northern end of Hatteras Island. Within the Refuge, the NPS is responsible for visitors and visitor facilities, while the USFWS is responsible for wildlife management.

Eight villages exist within the Seashore's authorized boundaries (seven on Hatteras Island), but are neither parklands nor a part of the Seashore. Only one village, Rodanthe, exists within the project area. The villages, the Seashore, and the Refuge are served by NC 12, a hard-surfaced, two-lane road approximately 50 miles (80 kilometers) in length bisecting the Seashore. By Act of Congress, the section of the Seashore encompassing the Refuge was to include a road. This road, which connects Rodanthe to Oregon Inlet, was completed in 1953 and was connected to Bodie Island to the north by Bonner Bridge in 1963. The NPS contributed funds ($500,000) to construct Bonner Bridge, which was considered a benefit to the Seashore at that time. The roadway, including the bridge, was officially designated as NC 12 in 1963; it is maintained by the NCDOT under agreements with the US Department of the Interior. NC 12 is the only road providing motor vehicle traffic through the Seashore. Vehicle access between Bodie Island and Hatteras Island is provided by Bonner Bridge across Oregon Inlet. The right-of-way or easement for NC 12 is 100 feet (30.5 meters) wide.

Access to Ocracoke Island is provided by the Hatteras Inlet ferry between Hatteras Island and Ocracoke Island, as well as by two NCDOT ferry routes operating between Ocracoke Island and the mainland. Ocracoke Island is outside the project area and thus not discussed in detail.

The Cape Hatteras National Seashore is a Section 4(f) resource, but the NC 12 right-of-way is not considered to be a Section 4(f) property. (See the introduction to Chapter 5 for a definition of Section 4(f) resources.)

3.5.1.1 Facilities

Seashore facilities administered by the NPS on Bodie Island are:

- Whalebone Junction Information Station;
- Bookstore;
- Coquina Beach Day Use Facility;
- Bodie Island Visitor Center and Nature Trail;
- Bodie Island Lighthouse;
- Oregon Inlet Campground*; and
- Oregon Inlet Marina and Fishing Center*.

Seashore facilities on Hatteras Island (including those within the Refuge) are:

- Refuge Visitor Center, wildlife trails, and boat ramp*;
- Rodanthe fishing pier;
- Little Kinnakeet US Life Saving Service Station;
- Avon fishing pier;
- Hatteras Island Visitor Center and Nature Trail;
- Cape Hatteras Lighthouse;
- Cape Point Campground and Day Use Facilities;
- Frisco Campground; and
- Frisco area fishing pier.

*Facilities marked with an asterisk (*) are in the project area.

The Atlantic Ocean beach south of Whalebone Junction is completely within the Seashore and is open for public use beginning about 5 miles (8 kilometers) south of Whalebone Junction (see Figure 5-1). The Oregon Inlet Marina and Fishing Center and the Oregon Inlet Campground are the only Seashore facilities located near the Parallel Bridge Corridor alternatives (including the Preferred Alternative), the Pamlico Sound Bridge Corridor alternatives, and the existing Bonner Bridge (see Figure 5-3). An unpaved beach access road intersects with NC 12 near the Marina and Fishing Center. Although not owned or maintained by the NPS, but rather the NCDOT, catwalks used by fishermen are attached to Bonner Bridge off Hatteras Island. There also are catwalks on the Bodie Island side, but they are now over land and are unusable for fishing. A parking lot and a path to the catwalks immediately south of Bonner Bridge are maintained by the NPS. The Refuge Visitor Center and its associated parking lot, the North Pond Wildlife Trail, and the boat ramp are all located near the Parallel Bridge Corridor alternatives (including the Preferred Alternative) (see Section 3.5.2).

3.5.1.2 Visitors

Statistics provided by the NPS in 2004 (see Table 3-7) indicated that visitors to the Seashore (irrespective of where they are staying) increased from 2,200,208 in 1990 to 3,077,940 in 2002—a 40 percent increase. Although the number of visits generally increased, the percentage of overnight stays decreased 41 percent between 1990 and 2002. Thus, not only was Hatteras Island use increasing, but an increasing proportion of residents and visitors to Dare County were taking day trips to Hatteras Island since most of the visitor facilities of the Seashore are on Hatteras Island. The 2002 monthly figures for recreational and non-recreational visitors to the Seashore in Table 3-8 illustrates the seasonal fluctuations of visitation levels and the greater summer season levels. Recreation visit statistics posted on the NPS web site show that the Cape Hatteras National Seashore (including Bodie, Hatteras, and Ocracoke islands) had 2,237,378 recreational visitors in 2007, indicating a decrease in visitors since 2002 (approaching 1990 levels). Overnight stays in 2007 were 96,934.

Table 3-7. Cape Hatteras National Seashore Annual Use

	Number of Visits				Overnight Stays	
	Recreation	Non-Recreation	Total	% Change from Previous Year	Total	% Change from Previous Year
1990	2,072,715	127,493	2,200,208	--	161,074	--
1997	2,515,057	130,367	2,645,424	--	111,367	--
1998	2,737,640	141,518	2,879,158	9%	103,676	-7%
1999	2,634,587	137,833	2,772,420	-4%	87,709	-15%
2000	2,647,383	136,743	2,784,126	0%	91,085	4%
2001	2,592,889	136,193	2,729,082	-2%	104,469	15%
2002	2,923,894	154,046	3,077,940	13%	95,297	-9%

3.5.1.3 Activities

Visitors to the Seashore enjoy a wide variety of recreational opportunities related to the unique natural, undeveloped, and protected character of the area. The NPS's Summer 2002 survey of Seashore visitors (University of Idaho, Summer 2002) provided the visitor participation statistics presented in Table 3-9 at its Outer Banks group of parks (the Seashore, the Wright Brothers National Memorial in Kill Devil Hills, the Fort Raleigh National Historic Site on Roanoke Island, and the Cape Lookout National Seashore), ranked according to activity popularity:

Table 3-9. Visitor Activities and Participation

Activity	Visitor Participation
Swimming/sunbathing	78%
Visiting historic sites	70%
Walking	65%
Enjoying solitude	56%
Photography	53%
Beach driving	36%
Picnicking	26%
Surf fishing	25%
Nature study	22%
Camping	21%
Surfing (wind/board/kite)	18%
Bicycling	17%
Canoeing/kayaking	13%
Charter boat fishing	9%
Attending ranger-led programs	9%
Boat fishing	7%
Other	11%

Note: The individual percents do not add up to 100 because visitors often participate in more than one activity.

Seashore lands in the project area are used for a variety of recreational activities, including:

- Camping at Oregon Inlet Campground on Bodie Island;
- Ocean fishing excursions from the Oregon Inlet Marina and Fishing Center;
- Surf fishing off Atlantic Ocean beaches;
- Fishing from the catwalks on the south end of Bonner Bridge;

- Surfing in the Atlantic Ocean;
- Wind-boarding (windsurfing) and kite surfing in Pamlico Sound;
- Walking along the beach;
- Birding and hiking on wildlife trails in the Refuge;
- Visiting the Refuge Visitor Center;
- Cycling along NC 12;
- Fishing from the Rodanthe fishing pier; and
- Driving the "Outer Banks Scenic Byway," which includes NC 12 from Whalebone Junction south through the Seashore.

3.5.1.4 Plans

The *General Management Plan and Amended Environmental Assessment for Cape Hatteras National Seashore* (NPS, 1984) and the *Draft Revised Statement for Management* (NPS, 1991) serve as the current NPS plans for the Seashore. These documents are described in Section 3.1.3.3. Completion of a new General Management Plan is scheduled for 2010 or 2011.

As discussed in Section 3.1.3.3, no new Seashore facilities are planned in the project area. The Seashore's plans focus on restoration and maintenance of existing facilities. The plans also support the construction of bicycle lanes along NC 12.

The *Cape Hatteras National Seashore Long-Range Interpretive Plan* (September, 2007) provides a vision for the future of interpretation at the Seashore. This document is described in Section 3.1.3.3. The plan includes goals related to improving personal services and visitor facilities, but none of the visitor facilities referenced for improvement are in the project area.

3.5.1.5 Natural Resources

The Seashore provides habitat for a wide variety of wildlife. Extensive marine and estuarine systems exist within the Seashore. The sand and mudflats on the south end of Bodie Island attract many shorebirds. In the portion of the Seashore through which the proposed project would pass, the most common plant community/habitat type is "Man-dominated." Seven types of wetland communities also are located within the Seashore portion of the project area. (See Section 3.7.4 and Figure 3-7 in Section 3.7.2.1 for a full description of habitats.) Eighteen protected species are documented in the project area and/or have suitable habitat within the project area (see Section 3.7.7).

3.5.2 Pea Island National Wildlife Refuge

The Pea Island National Wildlife Refuge (5,834 acres [2,361 hectares]) was established in Dare County on the northern end of Hatteras Island in 1938 by President Roosevelt through Executive Order 7864 (see Figure 3-1b). The Refuge was created in recognition of the importance of the area for wildlife. Executive Order 7864 reserved the area for migratory birds and other wildlife to advance the purposes of the Migratory Bird Conservation Act of 1929. The Refuge was named

for the once-abundant dune peas in the area that attracted waterfowl and was developed by CCC projects in the 1930s. The boundaries of the Refuge generally overlap with the boundaries of the Seashore north of Rodanthe. The Refuge is managed by the USFWS; however, a Memorandum of Agreement is in place so that the parking lots and comfort station on Hatteras Island are managed by the NPS. The USFWS is responsible for the natural resources management within the Refuge. (Personal communication, September 15, 2003, Dennis Stewart, USFWS, Pea Island National Wildlife Refuge, Manteo, NC.) As a first priority, federal law and regulation require the Refuge manager to ensure that all uses of the Refuge are compatible with Executive Order 7864 and the National Wildlife Refuge System Improvement Act of 1997, and that any allowed use of the Refuge be compatible with the mission ("wildlife first") and purpose of the Refuge. The primary purpose of the Refuge is to be a refuge and breeding ground for migratory birds and other wildlife.

The Refuge is a Section 4(f) resource. In addition, it is a significant publicly owned recreation area and also a significant historic site eligible for inclusion in the NRHP.

The Refuge is owned by the federal government and administered by the USFWS. Executive Order 7864 also established a boundary for the Refuge, which extends to the mean high tide level on both sides of Hatteras Island. The northern boundary of the Refuge extends to Oregon Inlet and the southern boundary is immediately adjacent to private properties in Rodanthe (see Figure 3-1c). Proclamation Boundary Waters also were established in 1938 around the Refuge but are not a part of the Refuge. This is an area that extends into Pamlico Sound to protect migratory birds from hunters in areas adjacent to the Refuge. The Proclamation Boundary Waters cover approximately 25,700 acres (10,400 hectares) of Pamlico Sound. All of the Refuge overlaps with a portion of the Cape Hatteras National Seashore.

Like the Seashore, NC 12 provides the primary access to and through the Refuge. NC 12 runs the full length of the Refuge south to north, as decreed by Act of Congress. The length of NC 12 (south to north) within the Refuge between Rodanthe and Oregon Inlet is approximately 11.8 miles (19.0 kilometers). The width of the Refuge ranges from 0.25 mile (0.4 kilometer) to 1 mile (1.6 kilometers) from east to west. The area was historically used for market waterfowl hunting, commercial fishing, farming, and livestock operations (Pea Island National Wildlife Refuge web site, August 18, 2008).

Currently, a 23-person staff administers both Pea Island and Alligator River (in mainland Dare County) National Wildlife Refuges. Numerous volunteers devote approximately 25,000 hours each year to the Refuge (*Comprehensive Conservation Plan*, Pea Island National Wildlife Refuge, 2006).

Like the Seashore, NC 12 provides the primary access to the Refuge. NC 12 runs the full length of the Refuge south to north. NC 12 is in an easement authorized by a permit from the USFWS.

3.5.2.1 Administrative and Management Law

The National Wildlife Refuge System Administration Act of 1966 created and provides for the administration and management of the National Wildlife Refuge System (NWRS). This system includes wildlife refuges, areas for the protection and conservation of fish and wildlife threatened with extinction, wildlife ranges, game ranges, wildlife management areas, and waterfowl production areas.

The National Wildlife Refuge System Improvement Act of 1997 amends and builds upon the 1966 Act to ensure that the NWRS is managed as a national system of related lands, waters, and interests for the protection and conservation of our nation's wildlife resources. The 1997 Act further defines the mission of the NWRS as to "administer a national network of lands and waters for the conservation, management, and where appropriate, restoration of the fish, wildlife and plant resources and their habitats within the United States for the benefit of present and future generations of Americans." The 1997 Act also requires the US Secretary of the Interior to ensure the biological integrity, diversity, and environmental health of the NWRS is maintained, and it defines compatible wildlife-dependent recreation as "legitimate and appropriate general public use of the System." It establishes hunting, fishing, wildlife observation and photography, and environmental education and interpretation as "priority public uses" where compatible with the mission and purpose of individual national wildlife refuges. The 1997 Act also retained the refuge managers' authority to use sound professional judgment in determining compatible public uses on national wildlife refuges and whether or not they will be allowed, and established a formal process for determining "compatible use." Proposed uses must be concurrently evaluated for compatibility with refuge goals, objectives, and the refuge's establishing legislation. This evaluation, known as a Compatibility Determination, also requires public notice and comment. However, the 1997 Act was not intended "to in any way change, restrict, or eliminate" existing road right-of-ways within refuges.

3.5.2.2 Refuge Purpose and Objectives

The primary purpose of the Refuge is to be a refuge and breeding ground for migratory birds and other wildlife. Refuge objectives are to:

- "Provide nesting, resting, and wintering habitat for migratory birds, including the greater snow geese and other migratory waterfowl, shorebirds, wading birds, raptors, and neotropical migrants.
- Provide habitat and protection for endangered and threatened species.
- Provide opportunities for public enjoyment of wildlife and wildlands resources. Public use programs focus on interpretation, environmental education, wildlife observation, wildlife photography, and fishing" (Pea Island National Wildlife Refuge web site, August 18, 2008).

3.5.2.3 Facilities

Facilities within the Refuge are shown in Figure 3-1b. They are:

- Salt Flats and North Pond Wildlife Trails;
- Refuge Visitor Center;
- Fishing catwalks at Oregon Inlet;
- A boat ramp;
- Seven parking lots; and
- Headquarters buildings.

The beach is open to the public.

3.5.2.4 Visitors and Their Activities

Based on traffic counts, the Refuge receives 2.7 million visitors annually (Pea Island National Wildlife Refuge web site, August 18, 2008). Most vehicles, however, only pass through the Refuge to and from other destinations on Hatteras Island. Refuge management estimated the number of visitors with the Refuge as a destination to be about 420,000 persons in 2003 and 540,000 persons in 2004. These rough estimates assume that about 80 percent of the vehicles counted are only passing through the Refuge. The peak-season for visitors to the Refuge is June through October.

During the summer peak-season, many families visit the Refuge to participate in typical beach activities. The peak-season for birding is in the fall, but it is also popular in the spring and winter. The peak-season for fishing is also in the fall. All activities in the Refuge during the winter are weather dependent; on many cold and windy days, there is little activity in the Refuge, but nice winter days can be relatively active. Weekends are not necessarily the busiest times in the Refuge because many locals use the Refuge during the week to conduct their activities, including participating in programs put on by the Refuge during the week (Friday is the busiest day for Refuge programs). In particular, retirees and birders visit the Refuge during the week. "Wings over Water" is a program put on by the Refuge staff for birders and other wildlife enthusiasts each fall. It is a large program that visitors come to the Outer Banks specifically to participate in, as opposed to many of the Refuge's other programs that people tend to find out about and participate in while visiting the Outer Banks for other reasons. (Personal communication, February 10, 2005, Bonnie Strawser, USFWS, Manteo, NC.)

Members of the EIS study team conducted site visits during the summer (peak-season), the fall (shoulder-season), and the winter (off-season) in order to obtain information on the seasonality of the numbers of visitors and the types of visitors' activities. The peak-season (Labor Day weekend, September 4 and 5, 2004) and shoulder-season (mid-October weekend, October 16 and 17, 2004) site visits included informal (scientific sampling was not used) parked vehicle counts and visitor interviews. Additional parked vehicle counts were also conducted on an off-season weekend (February 11 and 12, 2005). Vehicles counts were conducted by two-person teams driving the length of NC 12 within the Refuge one time at five different time periods during the day. The catwalks parking lot had by far the highest total number of parked vehicles (992) over the three weekends. The Visitor Center lot had the second highest total (177), but it was less than one-fifth of the total at the catwalks parking lot. The Visitor Center lot also serves the North Pond Wildlife Trail that follows the dike around North Pond. The third highest total (93) was at the parking lot on the east side of NC 12 north of the boat ramp, closely followed by the parking lot on the east side of NC 12 north of Salt Flats Trail (92). The highest total along the side of the road (87) was between Milepost Markers 37 and 38 (in the southern third of the Refuge), which is a popular surfing area. These parking patterns reflect that the most popular parts of the Refuge are towards the north, away from the Refuge's Rodanthe area entrance.

The EIS study team observed and counted visitor activities at the location of parked cars during the September and October weekends. Table 3-10 provides a summary of the visitor activities observed.

During both weekends, the predominant activity observed in the Refuge was fishing, either from the catwalks, the groin, the rock sea walls on both sides of the bridge, or surf fishing from the beach. All of these combined for approximately 52 percent of the total activities observed in September and approximately 61 percent of the activities observed in October. During September, surfing and general beach activities (e.g., sunbathing) each accounted for approximately 21 percent of the total activities observed. However, during October, these activities had reduced substantially and birding accounted for approximately 20 percent of the activities observed.

Table 3-10. Visitor Activities Observed (by Primary Activity, Month, and Number of Participants)

Primary Activity	September 2004		October 2004		Total	
	Number	Percent	Number	Percent	Number	Percent
Fishing from:						
• Catwalks	79	26.3	50	27.3	129	26.7

Total	**300**	**100.0**	**183**	**100.0**	**483**	**100.0**

Informal interviews were conducted with 167 visitors in September and October. Table 3-11 identifies the location of interviewees' homes. More than half of those interviewed over the two weekends were from out-of-state (approximately 57 percent), whereas approximately 29 percent were from other parts of North Carolina and approximately 14 percent were from the local area.

Table 3-11. Where Refuge Visitors Come From (by Month)

Home	September 2004		October 2004		Total	
	Number	Percent	Number	Percent	Number	Percent
Local Area	15	17.9	9	10.9	24	14.4
North Carolina	20	23.8	28	33.7	48	28.7
Out-of-State	49	58.3	46	55.4	95	56.9
Total	**84**	**100.0**	**83**	**100.0**	**167**	**100.0**

Table 3-12 presents the interviewees' frequency of visits to the Outer Banks. Approximately 18 percent of the interviewees said they only visit the Outer Banks occasionally (which included those who visit once every few years or this was their first visit). A similar percent of interviewees (approximately 17 to 18 percent) said they visited either once per year, or two to three times per year. Approximately 35 percent of those interviewed said they visit six or more times per year.

Table 3-12. Frequency of Visits to Outer Banks (by Month)

Visits per Year	September 2004		October 2004		Total	
	Number	Percent	Number	Percent	Number	Percent
One	10	12.8	17	20.5	27	16.8
Two/Three	11	14.1	18	21.7	29	18.0
Four/Five	5	6.4	6	7.2	11	6.8
Six or more	22	28.2	10	12.1	32	19.9
Non-Specific:						
• Occasional	10	12.8	19	22.9	29	18.0
• Several	6	7.7	3	3.6	9	5.6
• Often	14	18.0	10	12.0	24	14.9
Total	**78**	**100.0**	**83**	**100.0**	**161**	**100.0**

One factor in the selection of a Preferred Alternative was the effect on the use of the Refuge resulting from the loss of paved road access to the full length of the Refuge that would be associated with the Pamlico Sound Bridge Corridor. Therefore, visitors also were asked questions related to this potential change in access.

Table 3-13 presents the interviewees' responses related to whether or not there are other locations on the Outer Banks at which they could conduct their activities. Approximately 80 percent of the total number of interviewees indicated that they could do their activity at another location on the Outer Banks, whereas the other 20 percent said they could no longer enjoy their activity if the access to the Refuge was limited (i.e., by not maintaining paved road NC 12 access). However, approximately 85 percent of the visitors interviewed in September said there were other places to conduct their activity on the Outer Banks, whereas only 71 percent of those interviewed in October said there were other places. One reason for this difference is that there are a higher percent of birders and fishers in the fall months, and they are less likely than general beach-goers to state that there is another place to conduct their activity.

Table 3-13. Are There Other Locations to Conduct Activity (by Month)

Other Location?	September 2004		October 2004		Total	
	Number	Percent	Number	Percent	Number	Percent
Yes	57	85.1	30	71.4	87	79.8
No	10	14.9	12	28.6	22	20.2
Total	**67**	**100.0**	**42**	**100.0**	**109**	**100.0**

Table 3-14 presents the interviewees' responses related to whether or not they would still visit the Refuge if access was changed from a paved road to some other means of access (i.e., if visitors could no longer drive to their destinations within the Refuge, but rather had to take a tram or some other form of alternate access). As shown in Table 3-14, approximately 60 percent of visitors said they would still visit the Refuge with changed access; however, the percentage is slightly higher for visitors from the local area (approximately 67 percent) than for visitors from elsewhere in North Carolina (64 percent) or for visitors from out-of-state (56 percent).

Table 3-14. Would Visitors Still Visit Refuge with No Paved Road Access (by Home Location)

Still Visit?	Local Area		North Carolina		Out-of-State		Total	
	Number	%	Number	%	Number	%	Number	%
Yes	16	66.7	28	63.6	49	55.7	93	59.6
No	6	25.0	15	34.1	28	31.8	49	31.4
Maybe/Unsure	2	8.3	1	2.3	11	12.5	14	9.0
Total	**24**	**100.0**	**44**	**100.0**	**88**	**100.0**	**156**	**100.0**

Table 3-15 presents the interviewees' responses related to whether or not they would still visit the Refuge with changed access based on the activity they were participating in. As shown in Table 3-15, birding had the highest percent of visitors that would still visit the Refuge with changed access at approximately 78 percent, whereas general beach activities (i.e., sunbathing) had the lowest percentage at approximately 52 percent. One reason for this is that the Refuge is known as one of the best places in the area for birding and birders generally appear willing to use whatever access is available to visit the Refuge for participating in their activity. On the other hand, sunbathers can participate in their activity in numerous locations on the Outer Banks, so they are less willing to go out of their way to visit the Refuge for this activity. Table 3-15 also shows that approximately 54 percent of visitors fishing from the catwalks would still visit the Refuge with changed access, even with the potential loss of the catwalks.

Table 3-15. Would Visitors Still Visit Refuge with Changed Access (by Activity)

Primary Activity	Yes		No		Maybe/Unsure	
	Number	Percent	Number	Percent	Number	Percent
Fishing from:

Representatives of five Refuge user-related associations were interviewed. The Cape Hatteras Bird Club (CHBC) has more than 100 members (mostly from out-of-state and elsewhere in North Carolina). Most of the members visit the Refuge one to two times per year. Birders associated with this club choose all areas of the Outer Banks for birding, but in the winter months, the water fowl is the leading draw at the Refuge. (Personal communication, December 14, 2004, Pat Moore, Club President.)

The Cape Hatteras Anglers Club (CHAC) has 600 active members. Approximately 30 percent of them live on Hatteras Island, 20 percent live elsewhere on the Outer Banks, and 50 percent of them are from out of the area. The club's members use the Refuge for striper fishing in the fall, but the visits are infrequent. Very few of the CHAC members are bridge fishers; they are primarily surf fishers. (Personal communication, December 14, 2004, Larry Hardham, Club President.)

The Coastal Wildlife Refuge Society (CWRS) is a non-profit organization established and incorporated in 1989 by a group of local citizens. The purposes of the CWRS are twofold: 1) to generate funds to support Refuge programs and activities; and 2) to assist in the recruitment of Refuge volunteers. The CWRS designed, constructed, and staffs the Refuge Visitor Center, including the gift shop. According to President Tom White, the CWRS has approximately 50 to 60 local members, but they have many more members from outside of the local area who join in order to contribute to the CWRS' efforts. CWRS members visit the Refuge year round, but staff the Visitor Center for longer hours during the summer. In addition to providing staff for the Visitor Center, the CWRS also provides volunteers to work with the Refuge in other ways. (Personal communication, January 11, 2005, Tom White, President.)

The Eastern Surfing Association (ESA) is an organization for competitive surfers that covers the entire east coast of the United States. There are several districts within the ESA; one of them is the Outer Banks District. The Outer Banks District's membership is primarily from Dare County, although some of the membership is from Virginia Beach and Newport News, Virginia. Their members visit the Outer Banks all year long on a regular basis. The ESA hosts three or four contests per year in the Refuge between April and October. The ESA's annual eastern United States surfing championship is also held in the Refuge. During the peak summer season, the ESA's members choose to surf in the Refuge because there are too many people in Nags Head and other areas of the Outer Banks. In addition to the lack of crowds, the Refuge also has the best waves. (Personal communication, January 11, 2005, Julie Leavel, Outer Banks District Representative.)

The North Carolina Beach Buggy Association (NCBBA) has approximately 4,700 members nationally. Although ORVs are prohibited on the beach within the Refuge, NCBBA's members park on the shoulders of NC 12 within the Refuge throughout the year to gain access to many other activities (e.g., fishing, beach, etc.). The primary locations for off-roading for NCBBA members are within the Seashore to the north of Oregon Inlet and on Hatteras Island to the south of the Refuge. Many NCBBA members use their vehicles to transport fishing gear, surfboards, and other large recreational equipment into the Refuge. (Personal communication, March 11, 2005, Jim Keene, President.)

Three of the associations interviewed (Cape Hatteras Bird Club, Cape Hatteras Anglers Club, and Coastal Wildlife Refuge Society) believe that their members would continue to visit the Outer Banks with the loss of paved access through the Refuge. The Eastern Surfing Association and the North Carolina Beach Buggy Association, however, both stated that it is likely that fewer of their members from outside the local area would visit the Outer Banks under this scenario. If there was no paved road access to the Refuge, the ESA representative believes they would not be able to hold their surfing contests in the Refuge.

3.5.2.5 Plan

The USFWS prepared a *Pea Island National Wildlife Refuge Comprehensive Conservation Plan* (USFWS, 2006) to guide the management of the Refuge. The plan, which was published in September 2006, outlines programs and corresponding resource needs for the proceeding 15 years, as mandated by the National Wildlife Refuge System Improvement Act of 1997. The purpose of the plan is to identify the role that the Refuge will play in support of the mission of the National Wildlife Refuge System and to provide long-term guidance to the Refuge's management programs and activities. The plan is described in Section 3.1.3.4.

3.5.2.6 Natural Resources

The Refuge is comprised of ocean beach, dunes, upland, fresh and brackish water ponds, salt flats, and salt marsh (see Figure E-2 in Appendix E). Its bird list boasts more than 365 species; its wildlife list has 25 species of mammals, 24 species of reptiles, and 5 species (low number because of salt environment) of amphibians. Concentrations of ducks, geese, swans, wading birds, shore birds, raptors, and neotropical migrants are seasonally abundant in the Refuge. The Refuge has 1,000 acres (404.7 hectares) of manageable waterfowl impoundments. Several shorebird nesting areas and wading bird rookeries are on the Refuge. Endangered and threatened species include peregrine falcons, loggerhead sea turtles, and piping plovers (Pea Island National Wildlife Refuge web site, August 18, 2008).

Ten types of wetland communities also are in the Refuge portion of the project area (see Section 3.7.4). Eleven USFWS listed threatened or endangered species are documented in the project area and/or have suitable habitat within the project area (see Section 3.7.7).

3.5.2.7 Influence of Beach Erosion and Potential Breach Formation on the Refuge

Hatteras Island is eroding within the Refuge. Forecast 2010 to 2060 high erosion shorelines assumed in this FEIS are presented in Figure E-1 in Appendix E. Shoreline erosion is considered a natural process by Refuge officials and is preferable to artificially maintaining the shoreline, despite its threat to Refuge access and facilities.

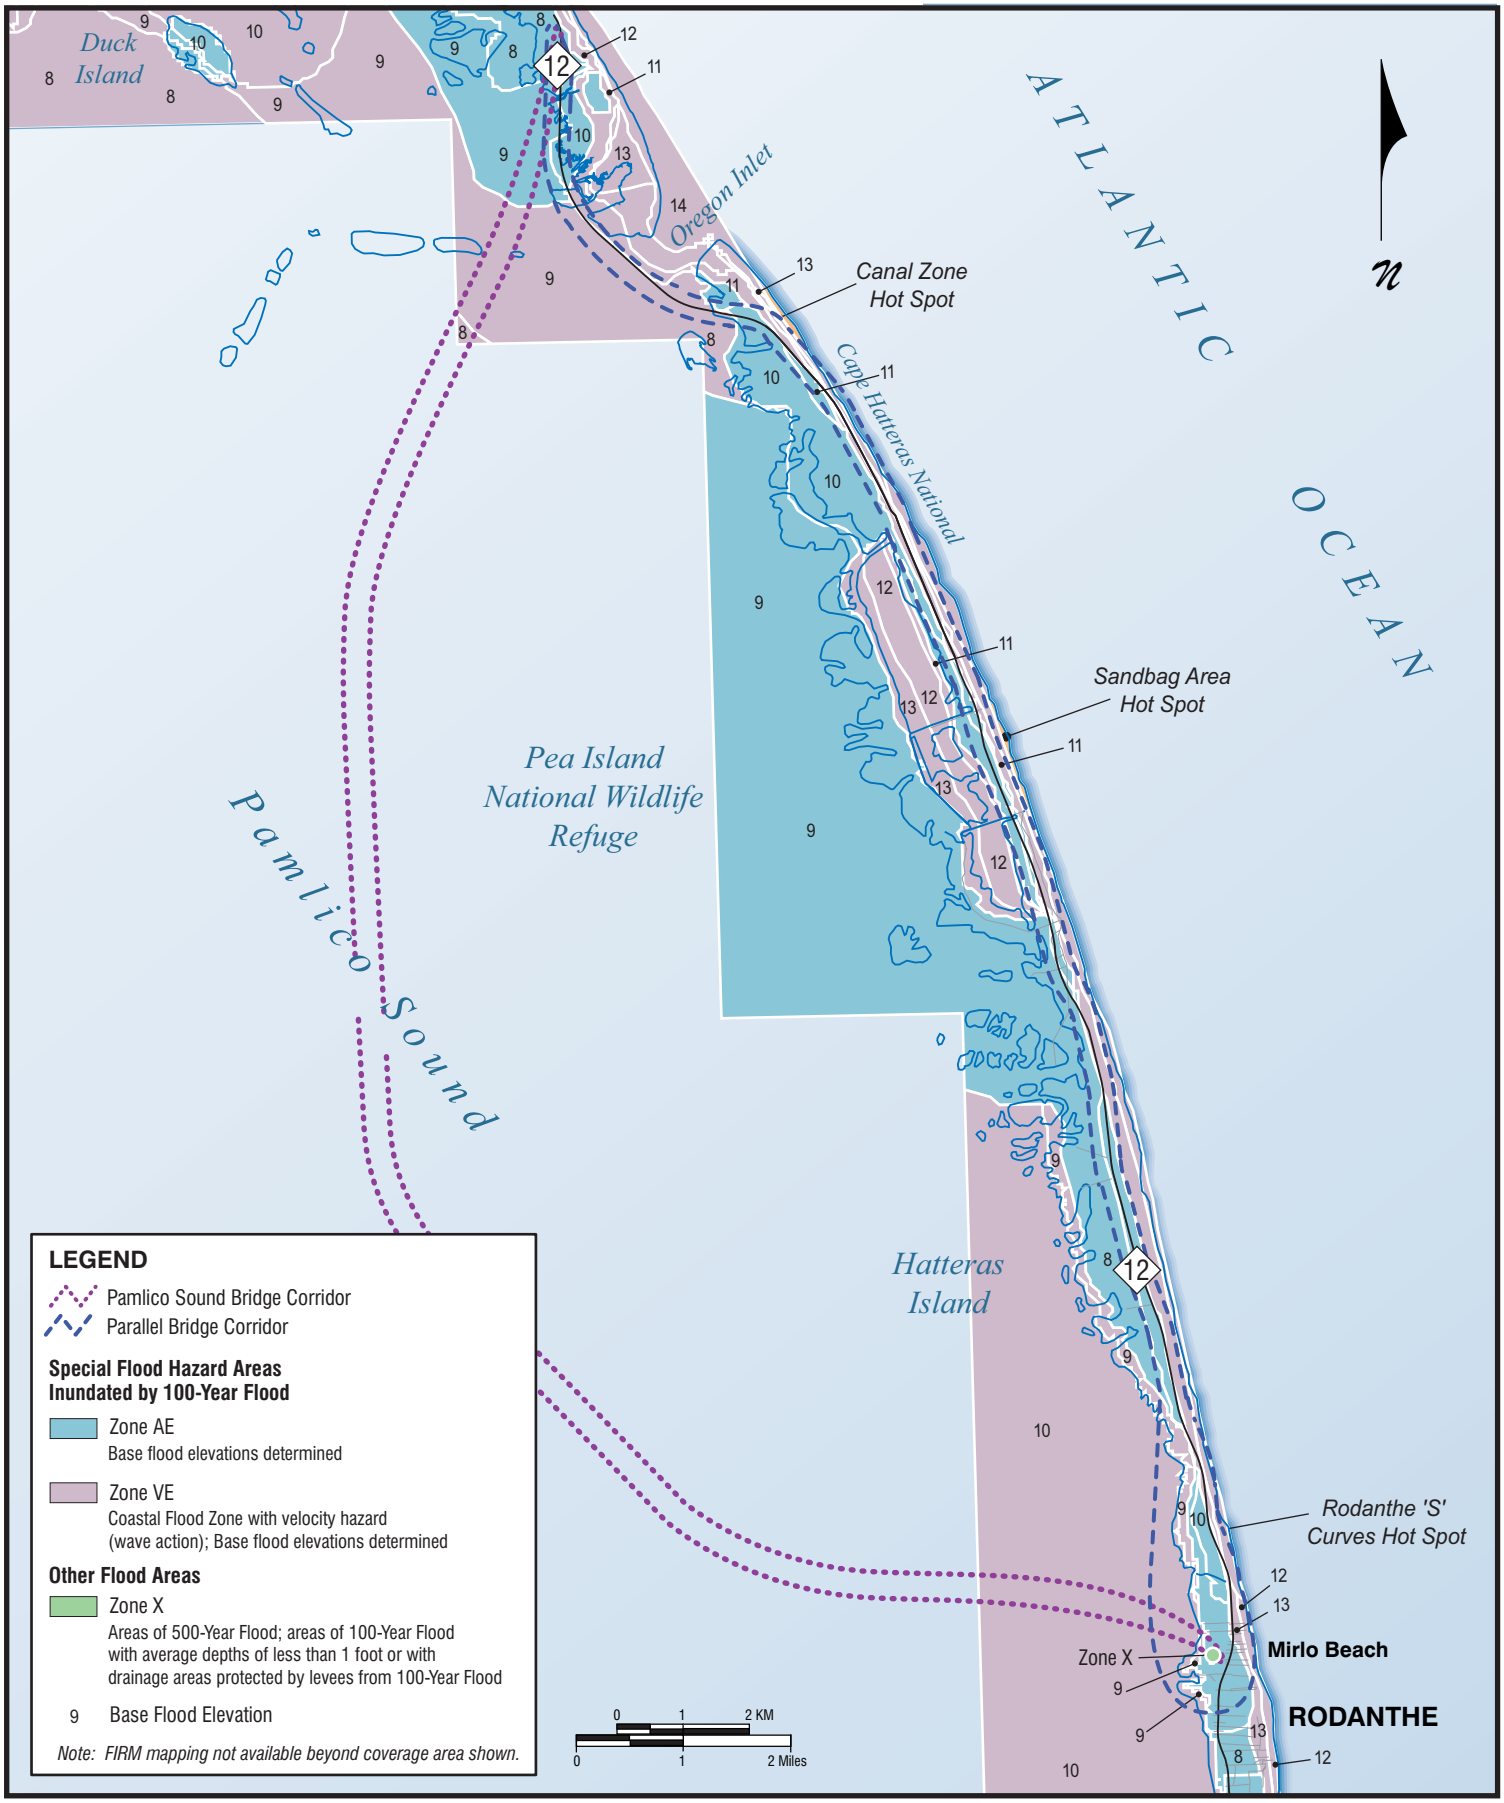
As indicated in Chapter 1, shoreline erosion and ocean overwash threaten to sever segments of the NC 12 roadway for several miles (kilometers) south of Bonner Bridge. The highest erosion rates occur in the northern Rodanthe area with an average of 15 feet (4.6 meters) per year. Erosion rates north the Refuge's ponds are as high as 8 feet (2.4 meters) per year. In addition, there is risk that NC 12 could be severed by a future breach at the south end of the Refuge. The formation of a breach in the Refuge would separate almost all of Hatteras Island and its associated communities, tourism businesses, and the Cape Hatteras National Seashore from Bodie Island and the mainland (see Section 3.6.3.4).

In addition to affecting NC 12, ongoing beach erosion would affect several Refuge features. The Refuge Visitor Center and headquarters will be threatened by 2020. By 2050, portions of the Refuge's freshwater ponds will have eroded into the ocean. Starting points for the North Pond and Salt Flats wildlife trails would be affected. Beach erosion at the southern end of the Refuge and/or future breach formation could result in all or part of the Refuge becoming a separate island.

3.6 Coastal Conditions

Coastal processes drive the physical changes in the Oregon Inlet area. This section first discusses the floodplains in the project area. Next, it documents and analyzes historic trends and existing coastal conditions, including:

- Inlet migration;
- Changes in inlet gorge alignment and location;
- Historic shoreline changes for Hatteras and Bodie islands; and
- The natural and manmade factors that drive inlet and shoreline changes.



Finally, this section presents projections of future coastal conditions, including:

- The Hatteras Island shoreline through 2060;
- Potential breach locations in the Pea Island National Wildlife Refuge; and
- Oregon Inlet movement through 2085 based on historical data.

The Hatteras Island shoreline material is derived from *Bonner Bridge Replacement – Parallel Bridge Corridor with NC 12 Maintenance – Shoreline Change and Stabilization Analysis* (Overton and Fisher, June 2005). The breach location findings are based on available research materials and the observations of an expert panel based on that research. The material on Oregon Inlet movement summarizes the coastal study findings of *Bonner Bridge Replacement: Oregon Inlet Movement Consideration* (Moffatt & Nichol, September 25, 2003). It is also based on three previous reports: *Existing Coastal Conditions at Oregon Inlet, North Carolina* (Moffatt & Nichol, June 1990), *Future Coastal Conditions at Oregon Inlet, North Carolina* (Moffatt & Nichol, October 1990), and *Coastal Engineering Technical Memorandum* (Moffatt & Nichol, July 1991).

3.6.1 Floodplains

The entire project area is within flood zones mapped by the Federal Emergency Management Agency (FEMA) under the National Flood Insurance Program (see Figure 3-4). In addition, much of the floodplain within the project area is classified as being a coastal flood zone with velocity hazard because of wave action. However, the floodplains in the project area do not serve the same function (i.e., as a natural moderator of floods) as floodplains in non-coastal areas because water levels in the project area are not dependent on floodplain storage capacity. Rather the project area is subject to coastal flooding caused by both hurricanes in the summer and fall months and northeasters in the winter and spring, both of which can raise water levels substantially via storm surge. The tidal surge comes into shore with the storm, and then begins to retreat almost immediately once the storm moves on. The only storage that occurs in the project area floodplains is during the brief interval between the surge and the ebb of the storm-induced tide. The 100-year storm surge elevation is 6.89 feet (2.1 meters), and the 500-year storm surge

Source: Flood Insurance Rate Maps dated September 20, 2006.

FLOODPLAINS

Figure 3-4

elevation is 7.58 feet (2.3 meters). Beneficial floodplain values are associated with this tidal surge. They are:

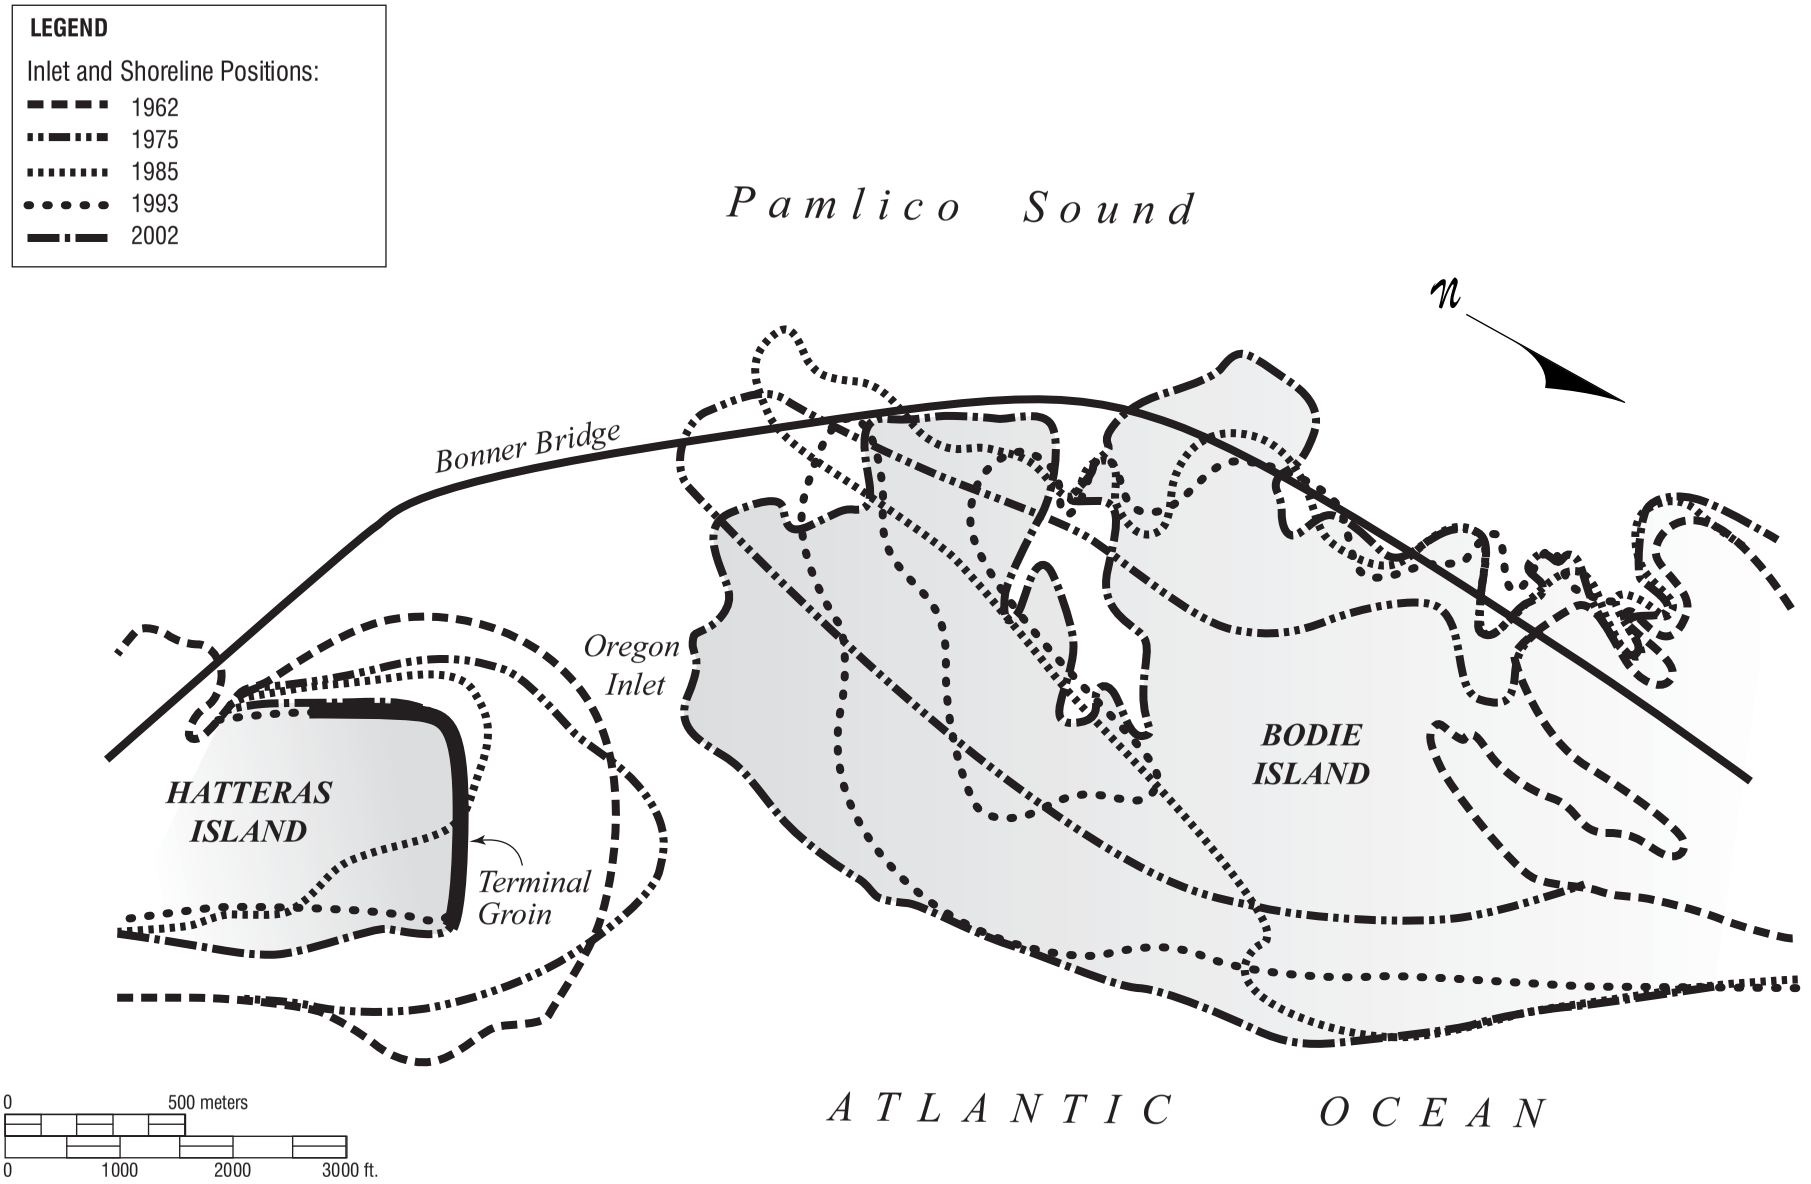
- Serving as a buffer (therefore flood control) to protect mainland shoreline areas by dampening tidal surges;

- Contributing to the natural barrier island evolution, whose benefits are discussed in Section 4.7.7; and

- Contributing to beneficial ecological change and habitat creation associated with barrier island evolution, also described in Section 4.7.7.

3.6.2 Existing Coastal Conditions

Oregon Inlet, Bodie Island, and Hatteras Island are part of a migrating barrier system characteristic of the southeast Atlantic Coast. The south end of Bodie Island is an actively prograding (growing) spit system that has back-filled the Bodie Island shoulder of Oregon Inlet with modern beach and island sediments as Oregon Inlet has migrated southward. Oregon Inlet is migrating south-southwest and historically has eroded the north side of Hatteras Island.



In this natural process, the north end of Hatteras Island (within 3 miles [4.8 kilometers] of Oregon Inlet) historically is a zone of high erosion. As a result of the continued inlet migration threatening the southern terminus of Bonner Bridge and the north end of Hatteras Island, the NCDOT built a terminal groin at the northern end of Hatteras Island to protect the southern approach to Bonner Bridge. The groin was designed by the USACE Wilmington District. Construction of the terminal groin began in October 1989 and was completed in March 1991. As a result of the construction of the terminal groin, Hatteras Island migration has halted. However, Bodie Island has continued to exhibit both along-shore and cross-shore migration. This continued migration has resulted in changes in both inlet width and orientation.

3.6.2.1 Inlet Migration

Since its opening during a storm in 1849, the midpoint of Oregon Inlet has migrated steadily southward just over 2.2 miles (3.5 kilometers) and landward approximately 2,070 feet (630 meters). The history of Oregon Inlet's migration has been punctuated by alternate widening and narrowing, typically in response to severe storms and primarily reflected by the erosion and accretion of the Bodie Island shoulder of Oregon Inlet. Inlet location changes since the opening of Bonner Bridge are illustrated in Figure 3-5. Until the construction of the terminal groin, the Hatteras Island shoulder moved steadily southward, showing little tendency toward significant accretion and northward movement. After construction of the terminal groin commenced, the southern migration of Hatteras Island halted. In recent years, Bodie Island has continued to accrete, causing Oregon Inlet width to narrow further, reaching a minimum width of 2,000 feet (610 meters) in 2002.

During the period from 1849 to 1945 (New Inlet, approximately 15 miles [24 kilometers] south of Oregon Inlet, closed in 1945), the Bodie Island shoulder migrated 6,000 feet (1,830 meters) or 63 feet (19 meters) per year south of its original position. Hatteras Island migrated 8,250 feet (2,510 meters) or 86 feet (26 meters) per year south of its original position.

From 1945 to 1989 (construction of the terminal groin began in 1989), the Bodie Island shoulder migrated 3,770 feet (1,150 meters) or 84 feet (26 meters) per year south of its original position.

Sources: US Army Corps of Engineers "Historic Changes in Oregon Inlet" and 1993 and 2002 aerial photography

INLET AND SHORELINE CHANGES

Figure 3-5

In that period, the Hatteras Island shoulder migrated 4,640 feet (1,410 meters) or 103 feet (31 meters) per year southward. The maximum inlet width of 6,670 feet (2,033 meters) was achieved in 1962, following a storm-laden period from 1953 through 1962, which culminated in the Ash Wednesday Storm of March 1962. The general tendency is for Oregon Inlet to widen after stormy periods, during which both shoulders of Oregon Inlet experience severe erosion. During calm periods, Oregon Inlet tends toward its minimum width of about 2,100 feet (640 meters).

The period from 1962 to 1983 generally was storm-free, and the Bodie Island shoulder spit redeveloped rapidly, accreting southward into Oregon Inlet for a total distance of 6,560 feet (2,000 meters) or 312 feet (95 meters) per year.

From 1983 to 1989, both the Bodie Island and the Hatteras Island shoulders eroded rapidly. The Bodie Island shoulder eroded 1,850 feet (560 meters) or 308 feet (94 meters) per year, and the Hatteras Island shoulder eroded 1,640 feet (500 meters) or 273 feet (83 meters) per year. However, between April 1988 and March 1989, the north end of Hatteras Island eroded at an extreme rate of 1,150 feet (350 meters) per year; with 350 to 400 feet (110 to 120 meters) of erosion occurring in the four-day period of March 6 to 10, 1989, when a severe northeaster storm pounded the coast. The width of Oregon Inlet increased steadily from 1,983 to 5,000 feet (605 to 1,520 meters) in 1989.

From 1990 to 2001, Bodie Island migrated southward 1,955 feet (600 meters) or 163 feet (50 meters) per year. Erosion of Hatteras Island was halted by the terminal groin during this period. Hatteras Island actually accreted 1,120 feet (340 meters) or 93 feet (28 meters) per year with the construction of the terminal groin.

Recent inlet position comparisons from September 2001 and March 2002 surveys show that Bodie Island's inlet shoulder advanced 443 feet (135 meters) over the six-month period. By March 2002, the spit had migrated almost two-thirds of the way across the preferred channel alignment projecting from the navigation span of Bonner Bridge. This updated rate of spit movement equals 886 feet (270 meters) per year.

3.6.2.2 Inlet Profile and Gorge Alignment

As Oregon Inlet migrated, the profile of Oregon Inlet (a cross-section through the narrowest point of Oregon Inlet) has changed configuration. The profile falls between two extreme shapes. Like the location of Oregon Inlet's shoulders, the shapes are related to stormy and storm-free periods. During relatively storm-free periods when the Bodie Island shoulder is in the shape of an elongated spit, the cross-section of Oregon Inlet is narrow but deep with steep banks. After stormy periods, when Oregon Inlet's shoulders are well-rounded, the configuration is a shallow channel with wide overbanks on one or both sides.

Conveyance (the ability to allow the passage of water) of Oregon Inlet generally has been stable since the most recent closure of New Inlet in 1945. The presence of multiple inlets on an estuary results in the separation of tidal flow volumes through each inlet. After New Inlet's closure, its effect on the behavior of Oregon Inlet was removed. During the past 60-year period, Oregon Inlet's conveyance was computed and found to vary by approximately 36 percent over this time. Changes in the cross-sectional area of Oregon Inlet have ranged from 37,440 to 58,700 square feet (3,480 to 5,450 square meters), an approximate 36 percent difference. Despite the changing shape of Oregon Inlet's cross-section, Oregon Inlet's hydraulic efficiency has been relatively stable.

The inlet cross-sectional area and hydraulic conveyance have decreased, however, since 1996. Since 1996, the cross-sectional area decreased by 29 percent, and the conveyance decreased by 24 percent; however, these values still fall within historical ranges. The groin tends to help create a narrower and deeper inlet.

The location of Oregon Inlet's gorge—or the deepest part of Oregon Inlet's cross-section—at times has remained relatively stable, but there is a constant tendency for the gorge to migrate southward. Dramatic shifts in the location of the gorge appear to be associated with the occurrence of major storms and are accomplished during short time frames. The gorge has tended to remain at the center of Oregon Inlet as the inlet migrates southward. After severe storms, however, when the Bodie Island shoulder has retreated northward substantially, the gorge has not also moved northward any great distance.

The movement of Oregon Inlet's gorge has created difficulty for the USACE in maintaining the navigation channel beneath the Bonner Bridge's navigation span. In the first few years after the completion of Bonner Bridge, the location of the channel through the navigation span was maintained by the natural scouring action of tidal currents. However, beginning in 1968, the shoaling rate for this part of the channel increased markedly as the fully developed sand spit on the Bodie Island shoulder began migrating southward toward the span. Bottom profiles have shown the gorge somewhere other than at the navigation span most of the time since 1971. Furthermore, the movement of the gorge has complicated the maintenance of the ocean bar channel. In 1981, the ocean bar channel adjacent to the south end of Bodie Island began to deteriorate, and a new bar channel formed in a more central location between Oregon Inlet's shoulders. Intense dredging efforts have failed to maintain desired depths for any substantial length of time.

3.6.2.3 Island Shoreline Changes

The island shorelines north and south of Oregon Inlet have eroded generally since the opening of Oregon Inlet in 1846. During the period from 1846 to 1980, both the Bodie Island shoreline and the Hatteras Island shoreline eroded at a rate between 10 and 20 feet (3 to 6 meters) per year. The greatest erosion rates occurred in the immediate vicinity of Oregon Inlet and declined with increased distance from Oregon Inlet.

Storms that occurred between September 9, 1960, and March 28, 1962, which included Hurricane Donna and the Ash Wednesday Storm, produced the most dramatic shoreline responses. The cumulative effect of the two storms was a general recession of the shoreline of both Hatteras and Bodie islands. The average annual erosion during this time (1960 to 1962) was approximately 200 feet (60 meters) per year, except near Oregon Inlet and just to the north on Bodie Island where the erosion averaged 389 feet (119 meters) per year. During severe storms such as Hurricane Donna and the Ash Wednesday Storm, sediment along the beach face generally moves offshore as the beach profile flattens to absorb the increased wave energy. During the recovery stage, sediment migrates onshore back to the upper portions of the beach profile. By October 1965, the recovery stage was basically complete.

During the next 10-year period (1965 to 1975, a relatively calm period), the areas adjacent to Oregon Inlet experienced slight accretion. The accretion along Bodie Island likely was associated with the redevelopment of the Bodie Island spit following the Ash Wednesday Storm.

From 1983 to 1990, there was a large build-up of material on the ocean shoreline of Bodie Island extending about 2 miles (3.2 kilometers) north from Oregon Inlet. Shoreline accretion rates

averaged about 180 feet (55 meters) per year directly adjacent to Oregon Inlet from November 1983 through January 1990.

Long-term average annual shoreline erosion rates along Bodie Island were released by the DCM through 1998. Within the first 2.5 miles (4.0 kilometers) north of Oregon Inlet on Bodie Island, the shoreline erosion was estimated to be 2 feet (0.6 meters) per year. Over the first 5.5 miles (8.9 kilometers) of shoreline north of Oregon Inlet, the observed shoreline change rates varied, ranging from 2 feet (0.6 meters) per year to 10 feet (3 meters) per year of erosion. Some areas north of Oregon Inlet have been influenced by beach nourishment projects either for beach protection or dredge disposal.

The shoreline of Hatteras Island near Oregon Inlet experienced severe erosion until the construction of the terminal groin began in 1989. From 1983 to 1989, the shoreline area extending 3 miles (0.9 kilometers) south of Oregon Inlet eroded at an average rate of 33 feet (10 meters) per year. During this period, erosion rates increased substantially in proximity to Oregon Inlet; within 6,000 feet (1,830 meters) of Oregon Inlet, the average erosion rate was 53 feet (16 meters) per year.

Long-term average annual shoreline erosion rates along Hatteras Island through 1998 also were released by the DCM. Within the first 0.5 mile (0.8 kilometers) south of the groin, the shoreline erosion was estimated to be 16 feet (4.9 meters) per year. Over the first 4 miles (6.4 kilometers) of shoreline south of the groin, the observed shoreline change rates were highly variable, ranging from 7 feet (2.1 meters) per year to 16 feet (4.9 meters) per year of erosion. In addition to these accelerated rates of erosion, three hot spots (Canal Zone, Sandbag Area, and Rodanthe 'S' Curves) or areas of concern with regard to beach and dune erosion, as well as highway vulnerability to overwash, were identified south of Oregon Inlet and in the project area. There are six such hot spots identified along the length of NC 12. In these areas, NC 12 is particularly vulnerable to overwash because of narrow beaches and low dune heights. See Section 1.1.3 for an additional discussion of these hot spots. The locations of the three hot spots in the project area are shown in Figure 1-1. A forecast of future shoreline erosion on Hatteras Island in the project area was developed and is discussed in Section 3.6.3.1.

3.6.2.4 Natural Factors Affecting Inlet and Shoreline Changes

Storms

The North Carolina coast is subject to two types of severe windstorms: extra-tropical northeasters and hurricanes. Northeasters, with accompanying high tides and waves, can rapidly erode the shoulders of Oregon Inlet. Northeasters are fairly common in this area, with between 30 and 35 of varying severity hitting the coast each year. Hurricanes may be responsible for major events, such as inlet openings and closings and gorge shifts, but because of their relative infrequency (approximately one hurricane every two years) and the north-northwest/south-southeast barrier island orientation, the overall impact of hurricanes is less significant than northeasters on this section of the coast.

Winds

Water levels in Oregon Inlet are determined mainly by local winds rather than by astronomical tides. Winds produce either an increase or decrease in water levels depending upon wind direction. Westerly and southerly winds substantially increase water levels in Pamlico Sound at Oregon Inlet, while easterly winds produce dramatic reductions in water levels. Storm surges associated with hurricanes and extra-tropical lows have dramatic impacts on Oregon Inlet by generating water level differences between the sound and the ocean, which potentially could be more than 10 feet (3 meters). The maximum sound water level of 7.5 feet (2.3 meters) over mean

sea level was recorded during Hurricane Donna, in September 1960; during the Ash Wednesday Storm in March 1962, the maximum ocean surge level of 8 feet (2.4 meters) over mean sea level was recorded.

Currents are mostly wind-determined and have been estimated to have reached a maximum of about 7 feet per second (2 meters per second) at the Bonner Bridge navigation span zone during the Ash Wednesday Storm (1962) and Hurricane Donna (1960), with even higher velocities at other points along the bridge. During model studies conducted by the USACE, a peak velocity of 17 feet per second (5 meters per second) in the Oregon Inlet channel was estimated to result from the combined effort of currents and the water particle velocities associated with passing waves.

Local Wave Climate

Significant wave heights at Oregon Inlet average about 3 feet (0.9 meters), with yearly extreme significant wave heights of at least 10 feet (3.0 meters). Research has indicated that waves of 5 feet (1.5 meters) or higher cause some degree of beach change along the mid-Atlantic coast barrier islands. Wave heights exceeding 5 feet (1.5 meters) occur approximately 10 percent of the time in the project area. The majority of the wave energy at Oregon Inlet comes from the northeast and east directions; this accounts for the southward migration of Oregon Inlet.

Scour

Local scour and the shifting navigational channel within Oregon Inlet often have threatened Bonner Bridge since its construction in 1962. Because of such conditions, numerous retrofits have been built.

Sand Bypassing

Sand is driven naturally by waves and currents along the coast until its movement is interrupted by an obstruction, such as a tidal inlet or a large manmade structure like a jetty. These obstructions tend to trap the sand and can cause the downdrift shoreline to erode because it becomes starved of its former supply of sand. In the case of Oregon Inlet, the downdrift shoreline is along Hatteras Island. Eventually, the obstruction becomes filled with sand and movement resumes. This is known as sand bypassing. For a tidal inlet, a common natural bypassing method is movement of sand along the large ebb tidal shoals that follow a curved path out into the ocean and span from one side of Oregon Inlet to the other. In order to mitigate the effects of man-made structures, natural sand bypassing can be supplemented or assisted by placing sand that is dredged from Oregon Inlet on the beach of the downdrift shoreline.

3.6.2.5 Navigation Channel Dredging Operations

Like all active tidal inlets, Oregon Inlet requires periodic dredging to maintain a navigation channel. In 1950, when the Oregon Inlet ocean entrance channel project was authorized, the channel configuration was specified as 14 feet (4.3 meters) deep at mean low water with a bottom width of 400 feet (122 meters). Maintenance dredging began in 1960, and, since then, the USACE has used hopper, sidecast, and ocean-going pipeline dredges for the work. Large amounts of dredging have been needed on a regular basis. Despite the large-scale efforts, however, the Oregon Inlet channel continues to migrate.

3.6.3 Future Coastal Conditions

Three aspects of future coastal conditions were considered. High erosion (i.e., assuming an erosion rate greater than past trends) Hatteras Island shorelines for 2010 to 2060 (in 10-year increments) were

developed primarily as an aid to determining the location and other requirements of the NC 12 maintenance component of the Parallel Bridge Corridor. The potential for a breach to occur in Hatteras Island within the project area was examined so that if a breach was likely, the cost of closing the breach and the economic loss to Dare County until the breach was closed could be considered in project decision-making. Finally, the potential for movement of Oregon Inlet with and without the terminal groin was considered, since that with the Pamlico Sound Bridge Corridor, the groin would no longer be needed to protect the southern terminus of a bridge across Oregon Inlet.

3.6.3.1 Hatteras Island Shoreline through 2060

The forecast 2010 to 2060 high erosion shorelines in the project area on Hatteras Island are shown at 10-year intervals in Figure E-1 of Appendix E. Long-term shoreline change was determined from an analysis of aerial photography and historic topographic sheets from the US Coast and Geodetic Survey dating from 1946 to 2004, a 58 year time period. Linear trends were determined for 106 transects (shoreline location cross-sections) within the project area from northern Rodanthe to Oregon Inlet.

The highest erosion rates occur in the northern Rodanthe area with an average of 11 feet (3.4 meters) per year. In the ponds area, the average rate is 7 feet (2.1 meters) per year. For the area north of the ponds, the erosion rate is approximately 5 feet (1.5 meters) per year.

In order to capture the uncertainty of predicting shoreline locations through 2060 with these data, 95 percent prediction intervals also were calculated from the data (i.e., a range of shoreline locations for which there is a 95 percent chance that the future shoreline will actually lay within these bounds). The width of the prediction interval depended on the variability and quantity of the historical shoreline data at each transect and therefore varied from transect to transect. The spatial average of the prediction interval in 2060 was found to be 240 feet (73.2 meters), with a maximum value of 600 feet (182.9 meters) and a minimum value of about 80 feet (24.4 meters).

The prediction of future shoreline position assumes that the trend in the shoreline change from the historical data will continue for the next 55 years. Because of the complex interactions that cause shoreline change, a high erosion shoreline (i.e., a shoreline that experiences an erosion rate greater than past trends) was assumed in developing alternatives for NC 12 maintenance through 2060. This high erosion scenario is assumed to be the upper bound (or landward extent) of the shoreline position range determined by the mean (average) plus the prediction interval. In addition, highway vulnerability to long-term erosion is defined as being susceptible to flooding and overwash when the distance from the edge-of-pavement to the active shoreline (i.e., the mean high water line) becomes less than or equal to 230 feet (70.1 meters) (i.e., the buffer width between the road and the ocean discussed in Section 2.6.2.1). This distance of 230 feet (70.1 meters) was added to the 2060 high erosion shoreline in order to establish the closest point to the ocean appropriate for NC 12 relocation alternatives. (The 2060 high erosion shoreline was referred to as the "2060 worst-case shoreline" in the SDEIS and SSDEIS.)

High erosion rates, when combined with narrow island widths in several locations, correspond with potential storm-caused Hatteras Island breach locations. The processes described above do not include potential alongshore and cross-shore changes that might occur if a breach forms and is allowed to remain open.

3.6.3.2 Sound-Side Erosion near Oregon Inlet

Erosion on the estuarine side of the terminal groin has developed since 1993. The observed erosion mimics the inner-bank erosion processes found in inlets stabilized with jetties (Seabergh,

2002). The ebb flow (tide returning to ocean) channel on the Hatteras Island side of Oregon Inlet has migrated to be relatively shore parallel. The channel currents have capacity to scour at the base of the rock revetment, the terminus of the protection for Bonner Bridge. The maximum shoreline erosion to 2006 is 275 feet (83.8 meters), and substantial shoreline change extends approximately 1,000 feet (304.8 meters) south of the rock revetment. Similar erosion in stabilized inlets with jetties has been observed to lead to breaching and subsequent isolation of the jetty from the shoreline (Seabergh, 2002).

If this inner-bank erosion continues near Oregon Inlet, it could contribute to breaching and could cause substantial changes in the geomorphology around the inlet. If the breach develops into an inlet just south of Oregon Inlet and isolates the terminal groin, this breach will compete with the existing Oregon Inlet for hydraulic control. In this case, the assumptions associated with the location of the navigation channel, the maintenance dredging required for the desired level of performance, and the long-term erosion expected south of the new inlet would be affected.

This potential for breaching, because of inner-bank erosion, is highly dependent on the characteristics of the ebb and flood (tide coming from the ocean) channels, associated ebb and flood deltas, and the impact these features have on the estuarine shoreline. Both long-term and short-term change resulting from storm events play an important role.

The potential breach can be accounted for in the Parallel Bridge Corridor alternatives that extend the Oregon Inlet bridge south of the inlet (with All Bridge and with Phased Approach [including the Preferred Alternative]) in the design of their substructure. The Pamlico Sound Corridor would bypass this location and associated issue.

3.6.3.3 Accelerated Sea Level Rise

As noted above, the data used to compute the shoreline change rates and the prediction intervals are derived from 58 years of shore line data. Thus any rise in sea level during that time is captured in the data. Data collected from 1978 to 2002 at Duck, North Carolina reveal past sea level rise trends in the area are 4.27 (+/-1.45) millimeters per year (0.17 inches per year, +/- 0.06 inches per year).

The potential for shoreline change because of accelerated sea level rise along the Mid-Atlantic region was recently reported by Gutierrez et al (2007) using four scenarios. The time frame was defined in this report as long-term, or up through the end of this century (i.e., 2100). The scenarios are:

1. A continuation of the 20th century sea level rise rate (accounted for in project shoreline change rates);

2. The 20th century rate + two millimeters (0.08 inches) per year;

3. The 20th century rate + seven millimeters (0.28 inches) per year; and

4. A two meter (6.6 feet) rise over the next few hundred years.

Scenarios 2 and 3 were developed to be within the range of increased rates presented by the Fourth Assessment Report of the Intergovernmental Panel on Climate Change (Bindoff et al., 2007) and are the two addressed in this Final Environmental Impact Statement (FEIS). For wave dominated barriers such as Hatteras Island, Gutierrez et al (2007) report that for scenario 2 it is "virtually certain" morphological change such as overwash, erosion and inlet formation will

continue, and that it is “very likely” that portions of the barriers will exhibit “threshold behavior.” Indicators of threshold behavior are "a) rapid landward recession of the ocean shoreline, b) decrease in barrier width and height, c) increased overwash during storms, d) increased barrier breaching and inlet formation, and e) chronic loss of beach and dune sand volume." For scenario 3, it is "about as likely as not" that there will be loss of the back barrier marshes and shallow shoals, leading to changes in the hydrodynamic conditions and thus the evolution of the barriers.

During the development of the FEIS, FHWA hosted a Peer Exchange workshop seeking to incorporate recent scientific research on global climate change effects and accelerated sea-level rise into the previous shoreline analysis for this project. The outcome of the Peer Exchange was to identify if any analytical gaps exist between the shoreline erosion forecast conducted for the project (see Section 3.6.3.1) compared to recent and relevant research on global climate change. The Peer Exchange included a panel of coastal engineering and geology experts with knowledge of the local area as well as experts with knowledge of recent research on global climate change. The Peer Exchange panelists agreed that there is not a good predictive model that should be considered further in regards to shoreline change as a result of accelerated sea level rise. Therefore, the best response to considering accelerated sea level rise is to address how the shoreline studies completed for this FEIS reflect the outcomes of accelerated sea level rise. As described in Section 3.6.3.1, the overall approach to the coastal analysis through 2060 in this FEIS takes into account shoreline change predictions based on past conditions and episodic events (e.g., formation of the inlets), data which is based on geologic and geomorphological characteristics, combined with site specific knowledge of the history of the barrier islands. The conditions expected to occur in the shoreline forecasts in this FEIS are precisely those which scenario 2 above considers “virtually certain” to occur (overwash, erosion, and inlet formation). Project planning acknowledges this expected certainty. The effect of uncertainties in determining exact location and timing of shoreline change are addressed to different extents by the detailed study alternatives, as discussed in the impact assessment in Chapter 4.

In the Rodanthe area, the shoreline issues reflected in project planning are consistent with the indicators of "threshold behavior", also a potential partial outcome of scenario 2:

- Rapid landward recession (forecast shoreline change);
- Decrease in barrier width and height, increased overwash, and loss of sand volume (reflected in the potential for storm maintenance activities in the Rodanthe area prior to the completion of the project; and
- The potential for a breach or inlet.

With scenario 3, the characterization is that sea level will rise at such a fast rate that the barrier islands will not have a chance to “roll over.” That is, the naturally expected overwash, deposition on the back barrier, erosion on the oceanside will not occur. Though not stated by Gutierrez et al, (2007), this will lead to further loss of island width and “threshold behavior” leading to island segmentation and disintegration.

3.6.3.4 Potential for Island Breaches

This section addresses potential breach locations, the potential for a breach to open in the project area, potential depth of breaches, and the potential affect of breach formation on coastal change assumptions.

Potential Breach Locations

The starting point for the consideration of potential breach locations was a draft product of the ongoing Coastal Cooperative Research Program, sponsored by East Carolina University, the US Geological Survey, and the North Carolina Geological Survey, which has been intensively studying the northeastern North Carolina coastal system since 2000. This study found that there are five potential breach locations within the Refuge (see Figure E-1 in Appendix E and Figure 2-8). The word "breach" is used rather than the word "inlet" because, if a breach were to occur, it would likely close eventually (although not necessarily immediately) and likely would not become a long-term phenomenon like Oregon Inlet. The one possible exception to this likelihood is Site 5 (described below). Following is a brief description of the characteristics of the five potential breach locations:

- Site 1. A molar-tooth (shaped) marsh platform with sand-filled overwash tidal channels underlies the entire barrier island. This site could open from either the ocean or the sound, with multiple channels that would be 100 to 300 feet (30.5 to 91.5 meters) wide and 10 to 25 feet (3.0 to 7.6 meters) deep (similar to the Hurricane Isabel breach that opened in 2003 at the north end of Hatteras Village).

- Site 2. The historic New Inlet (open during the early twentieth century) and associated flood-tide delta with one large sand-filled inlet channel underlying the entire barrier island. This breach could open from either the ocean or sound, with a single channel that could be 500 to 2,500 feet (152.4 to 762.2 meters) wide and 15 to 35 feet (4.6 to 10.7 meters) deep.

- Site 3. The historic Chickinacommock Inlet (open during the eighteenth and nineteenth centuries) with one large sand-filled inlet channel underlying the entire barrier island. This breach could open from either the ocean or sound, with a single channel that could be 500 to 2,500 feet (152.4 to 762.2 meters) wide and 15 to 35 feet (4.6 to 10.7 meters) deep (similar to the historic New Inlet).

- Sites 4 and 5. A single molar-tooth marsh platform has two sand-filled overwash tidal channels on each side of the platform that probably do not yet underlie the east side of the barrier island. However, in an exceptionally large storm or if Oregon Inlet is stabilized, the flooding or ebbing storm surge could flank the existing inlet channel and open small flanking channels that would be 100 to 300 feet (30.5 to 91.5 meters) wide and 10 to 25 feet (3.0 to 7.6 meters) deep or perhaps deeper adjacent to the terminal groin.

Breaching generally occurs during storm events and results from overtopping from the oceanside, elevated water levels and flow from sound to ocean, and/or seepage and liquefaction. Following a breach, the hydraulics of the system will dictate whether the breach grows into an inlet or whether it naturally closes. Longshore sediment transport (movement of sand along the ocean bottom parallel to the shore) will tend to close the breach, while the tidal exchange will tend to scour out the breach. Assuming that the flux (flow or movement of water) between ocean and sound is in equilibrium before the breach, the new breach will compete with the existing inlets for hydraulic exchange (water movement between the ocean and sound). In other words, the total hydraulic exchange quantified in terms of volume flow rate (e.g., cubic feet per second [meter per second]) could be split between multiple inlets. In addition, since flow rate is the product of average flow velocity times cross-sectional area, a wider inlet with smaller depths and velocity may exchange the same amount as narrower, deeper, higher velocity inlet. How this balance is achieved may either serve to continue the growth of the new inlet while closing down the old inlet, or it may serve to close the breach. A breach in the vicinity of a coastal structure (jetty,

terminal groin, etc.) has the potential to undermine the structure and/or isolate it (leave it surrounded by water). If the new inlet grows in size, the navigation channel of the existing inlet will likely shoal at a more rapid rate than previously observed. If the trend continues toward "closure" of the existing inlet, the navigation channel will have to be relocated in the new inlet (Kraus, 2003).

Potential for a Breach to Open in the Project Area

The information from the Coastal Cooperative Research Program provided the starting point for an expert panel that considered the likelihood that a storm would open a breach in Hatteras Island at one of these five locations by 2060. The expert panel also reviewed other models and techniques for inlet prediction and met to reach a consensus estimate on potential inlet formation. The panel members were:

- Dr. Robert Dean, coastal engineer, Professor Emeritus, University of Florida;
- Dr. Robert Dolan, coastal geologist, Professor, University of Virginia;
- Mr. Carl Miller, research oceanographer, Field Research Facility, USACE, Duck, North Carolina;
- Mr. Michael Wutkowski, coastal engineer, Wilmington District, USACE;
- Dr. Stanley Riggs, coastal geologist, Professor Emeritus, East Carolina University;
- Dr. Margery Overton, coastal engineer, FDH Engineering/Professor, North Carolina State University;
- Mr. Tom Jarrett, coastal engineer, FDH Engineering, recently retired head of the Coastal Processes Branch, Wilmington District, USACE; and
- Dr. John Fisher, coastal engineer, FDH Engineering/Professor, North Carolina State University.

Prior to the meeting of the expert panel, members were sent the recent potential inlet report prepared by Dr. Riggs as well as a paper written by Mike Wutkowski on the Hatteras Village breach closure. In addition, the panel was sent an overview of the problem and the objectives of the meeting.

There was general agreement that there is a risk of a storm-related breach forming in the southern part of the Refuge (Site 3) prior to 2060. In addition, a storm event of the nature required to create a breach would probably occur once during that period. The southern part of the Refuge is the location of a prior inlet, and this part of the island is very narrow with relatively small dunes. There is also a relic channel across the estuarine marsh.

There was little panel agreement for a storm-related breach to develop at the other potential locations in the next 50 years. The panel noted that there are several factors that might preclude the occurrence of a storm-related breach at any site other than the southern part of the Refuge. These factors include the proximity to Oregon Inlet, that the Rodanthe site is the weakest section, and the current shoaling in Pamlico Sound (e.g., Oregon Inlet Shoal, see Figure 3-7 in Section 3.7.2.1) at the north end of Hatteras Island because of the shift in the channel through Oregon

Inlet. Dr. Dean noted that beach nourishment would greatly reduce the potential for breach formation.

At Site 5 near Oregon Inlet and the terminal groin, erosion on the estuarine (sound) side of the terminal groin has been observed since 1993. The observed erosion mimics the inner-bank erosion processes found in inlets stabilized with jetties (Seabergh, 2002). The ebb flow (water flow back towards the ocean) channel on the Hatteras Island side of the inlet (Davis Slough) has migrated to be relatively parallel to the shore. The Davis Slough channel's currents provide the capacity for scour at the base of the rock revetment protecting the southern terminus of Bonner Bridge. As indicated by Seabergh, if left "unabated, a crenulated [notched or scalloped] shaped shoreline region will develop from the terminus…" The maximum shoreline erosion to date is 275 feet (83.8 meters), and substantial shoreline change extends approximately 1,000 feet (304.8 meters) south of the rock revetment. Similar erosion in stabilized inlets with jetties has been observed to lead to breaching and subsequent isolation of the structure from the shoreline (Seabergh, 2002). If this inner-bank erosion continues, the immediate vicinity of the terminal groin (the northern portion of Site 5) will become more vulnerable than was concluded by the panel. This potential for breaching because of sound-side erosion at Site 5 in the immediate vicinity of the terminal groin is highly dependent upon the characteristics of the ebb and flood (flowing in of the tide) channels and associated ebb and flood deltas (area of sediment deposits) and the impact these features have on the estuarine shoreline. Both long-term (e.g., erosion) and short-term change because of storm events are important.

Shoreline change on the ocean side at Site 5 is also dependent on the natural inlet processes, as well as on the continuity of USACE's maintenance dredging and disposal program for Oregon Inlet. Accretion of the shoreline has occurred just south of Oregon Inlet since 1993, and this accretion is reflected in the shoreline model used to determine the future shoreline positions described in Section 3.6.3.1. Two features serve to promote accretion in this location. One is the disposal of dredged material in this location by the USACE. The USACE placed dredged material in this location in 1991 and in 2004. Two additional times, sand has been placed just south of Site 5, potentially supplying sand to Site 5 to the north. Longshore sediment transport is south to north in the vicinity of the terminal groin. Evidence of this is seen in the material deposited on the inlet side of the terminal groin. In addition, the USACE has placed dredged material in the nearshore off of Hatteras Island, effectively bypassing sand around the inlet and keeping it within the littoral system. These features provide a sediment rich environment on the ocean side of Site 5, serving to reduce the vulnerability of this location to a breach because of ocean overwash, where as noted in the previous paragraph, soundside erosion increases the vulnerability for a breach near the terminal groin.

Potential Depth of Breaches

The tidal prism is the volume of water moving through an inlet between high and low tides (or alternatively low and high tides). If Hatteras Island is breached, the relationship between the tidal prism and the cross-sectional area of flow in Oregon Inlet will be altered. Opening a breach will increase the inlet cross-sectional area of the two inlet system and will tend to decrease the velocities in the existing inlet (Kraus and Wamsley, 2003). It is not possible to precisely predict the depth and cross-sectional areas of the potential breaches given the unknowns (e.g., magnitude and duration of the storm, storm track, water elevation in the sound) related to the storm scenarios that might trigger a breach. Further, breaches have been documented to grow in depth and width after opening.

Documentation of breaching on Hatteras Island indicate varied depth responses. The breach on Hatteras Island that opened near Hatteras Village as a result of Hurricane Isabel in 2003

developed three channels that were truncated by more resistant peat filled deposits in between the channels. The west channel developed depths of 8 to 10 feet (2.4 to 3.0 meters), the middle channel approximately 5 feet (1.5 meters), and the east channel up to 20 feet (6.1 meters) before it was closed (Wamsley and Hathaway, 2004). Just north of Buxton, the Ash Wednesday storm opened a breach (Buxton Inlet) which developed depths of 8 to 11 feet (2.4 to 3.4 meters) before being closed (Wamsley and Kraus, 2005).

A review of historic US Coast and Geodetic Survey Hydrographic charts available through National Oceanic and Atmospheric Administration (NOAA) Historical Map and Chart Project reveals one chart with depth soundings during a period when both Oregon Inlet and New Inlet were open. At that time, 1913, Oregon Inlet is mapped with maximum depths of 4 fathoms (24 feet/7.3 meters) while New Inlet has a maximum depth of 2.5 fathoms (15 feet/4.6 meters). Later charts (1932, 1933) show New Inlet to be closed but indicate up to 11 feet (3.4 meters) of depth in the sound side channel associated with the historic location of New Inlet. The 1942 charts show New Inlet to be open, but no soundings are charted within New Inlet or the remnant sound side channels. Oregon Inlet is charted with a maximum depth of 32 feet (9.8 meters).

Recent experience with barrier breaching on Hatteras Island, as well as the documented relationship between Oregon Inlet and New Inlet (and assuming similar storm characteristics), suggest that expecting up to 10 to 20 feet (3.0 to 6.1 meters) post-storm depths in the three potential inlet sites (i.e., Sites 1, 2, and 3) from Rodanthe to the New Inlet area south of the Refuge's ponds would be reasonable given the range of what has been observed. At the northern-most sites, as described in Section 3.6.3.2, inner-bank erosion near Oregon Inlet could contribute to breaching and could cause substantial changes in the geomorphology around the inlet. If the breach develops into an inlet just south of Oregon Inlet and isolates the terminal groin, this breach will compete with the existing Oregon Inlet for hydraulic control. In this case, depths of a breach at the north end of Hatteras Island would be similar to depths experienced in Oregon Inlet.

Effect of Breach Formation on Coastal Change Assumptions

If breaches at Sites 1, 2, or 3 were to remain open, they would compete hydraulically with Oregon Inlet; however, the separation distance between the inlets would affect how the flow patterns between the ocean and the sound would be reestablished. In addition, the location of the throat of the inlet and the influence of the inlet on the up and downdrift beaches would affect predicted shoreline change. Shoreline change estimates presented in Section 3.6.3.1 would have to be reconsidered once a new dynamic is achieved. As noted in the previous section, Site 3 is the most likely location for a future storm-related breach.

Site 4 is close enough to Oregon inlet to compete for hydraulic exchange and thus potentially change the preferred location for maintaining a navigation channel. Further, shoreline change estimates between Oregon Inlet and an inlet at Site 4, as well as the area south of Site 4, would be affected by the opening of a breach at Site 4. However as noted in the previous section, the likelihood of an inlet forming in this location is thought to be less than other locations. In addition, a comparison of 1993 and 2006 aerial photographs indicates that sound-side erosion has not occurred in the Site 4 area since 1993 to the extent it has at Site 5.

For Site 5, the close proximity of the potential breach to the terminal groin suggests that an opening in that location could affect the performance of the terminal groin in terms of accelerated destabilization and increased costs of repair, as well as result in increased costs for channel maintenance dredging and loss of navigability in Oregon Inlet (based on Kraus and Wamsley's list of ten impacts of an unintended breach in a barrier island, 2003). A breach from the sound side just south of Oregon Inlet (Site 5) could cause substantial changes in the geomorphology

(development of the land forms) around Oregon Inlet, particularly if the breach isolates the terminal groin from Hatteras Island and the existing channel shoals (fills in or becomes more shallow). Thus, unlike other potential breach locations, a breach at this location is more likely to become permanent and deep. In this case, the assumptions associated with the location of the navigation channel, the maintenance dredging required for the desired level of performance, and the long-term erosion expected south of the new inlet would necessarily change.

3.6.3.5 Oregon Inlet Movement Through 2085

As described above, the Oregon Inlet area is highly dynamic. In order for a replacement crossing to be sited properly in either of the project corridors, future inlet migration, shoreline erosion/ accretion, and channel movement and depth must be predicted, taking into account naturally occurring and man-induced influences.

The permit from the Refuge that allowed the construction of the terminal groin states that the purpose of the terminal groin is to: "…protect the southern segment of the existing Herbert C. Bonner Bridge and its southern approach of North Carolina Highway 12." The permit also states that the NCDOT can use the lands and waters occupied by the terminal groin for as long as they "are used for the purpose granted." The NCDOT has no current plans to remove the terminal groin on Hatteras Island after Bonner Bridge is demolished. If an Oregon Inlet bridge were built in the Parallel Bridge Corridor, the groin would be needed to protect its south approach, just as it currently protects Bonner Bridge's south approach. If a bridge were built in the Pamlico Sound Bridge Corridor, the terminal groin could serve parties other than the NCDOT and other immediate needs besides protecting Bonner Bridge or its replacement. It is conceivable, however, that circumstances could change at some time in the future, and it could prove prudent to remove the terminal groin if the Pamlico Sound Bridge Corridor is used for the replacement bridge. A new Special Use Permit for the retention of the terminal groin and revetment would be required if it is to remain in place with any of the replacement bridge corridor alternatives once Bonner Bridge is demolished. Without a new permit, the NCDOT would be obligated under the terms of the existing permit to remove the terminal groin and revetment two years after the construction of a replacement bridge at the request of the USFWS.

Thus, the effects of both the continued presence and the removal of the terminal groin on Oregon Inlet were examined, and these would be considered when placing the navigation zone as described for the proposed bridge in the Pamlico Sound Bridge Corridor in Section 2.9.2. For the Oregon Inlet bridge in the Parallel Bridge Corridor, the navigation zone would span much of Oregon Inlet. Findings presented below are based entirely on engineering judgments derived from a critical review of the information presented in the report, *Bonner Bridge Replacement: Oregon Inlet Movement Consideration* (Moffatt & Nichol, September 25, 2003). No quantitative analyses or numerical modeling were performed. At the time of the study in 2003, it was assumed that if a bridge were build in the Pamlico Sound Bridge Corridor that the project would be complete by 2010 and the groin removed at that time. The findings of the post-groin removal Oregon Inlet movement trends described in this section would begin in whatever year the groin would be removed and the constraint on inlet movement applied by the groin is released.

Oregon Inlet Conditions with the Terminal Groin

As of March 2002, the Bodie Island spit has migrated almost two-thirds across the preferred natural channel alignment projecting from the navigation span of Bonner Bridge. Between 1999 and 2001, the channel gorge at the narrowest cross-section had moved south approximately 830 feet (250 meters). If left unattended, the migration of Bodie Island likely will engulf the existing navigation span and channel, and scour could become a potential threat at the terminal groin on

Hatteras Island. The rate of spit movement could not continue to be as great as 886 feet per year (270 meters per year) (see Section 3.6.2.1) over the next 10 to 15 years with the terminal groin remaining in place. At that rate, Oregon Inlet, which is approximately 2,000 feet (610 meters) wide, would have closed within only three years.

Until the proposed project is completed, it is assumed that the USACE will use dredging to maintain the navigation channel by trimming off the end of the Bodie Island spit. This will result in Oregon Inlet maintaining an almost constant width of 2,000 feet (610 meters), assuming no major storm activity. Oregon Inlet dredging will help to channel a large volume of water through the navigation span section, thereby increasing water velocities at that location and reducing the propensity for Oregon Inlet's gorge to move farther south toward the terminal groin. The gorge depth should remain generally constant barring any extreme storm activity.

After the construction of the proposed project, it is assumed the USACE will cease to dredge a channel at the Bonner Bridge navigation span, given the flexibility of either the long navigation zone with the Parallel Bridge Corridor or the lack of a navigation span in Oregon Inlet (but rather further back in Pamlico Sound) with the Pamlico Sound Bridge Corridor. As a result, Oregon Inlet likely will narrow slightly, but it is not expected to close completely because of the tidal prism that must continue to pass through Oregon Inlet. Also, the gorge might re-establish its historical migration southward toward the terminal groin.

Short-Term Impacts of the Removal of the Terminal Groin

Should the terminal groin be removed at some point after completion of a bridge in the Pamlico Sound Bridge Corridor, the ocean shoreline could respond initially by adjusting back to a position that corresponds to a continuation of historic trends. This means that substantial shoreline erosion could occur on the northern end of Hatteras Island. Since Oregon Inlet is currently very narrow compared to historical trends, Oregon Inlet likely would widen and become shallower, while maintaining a consistent conveyance as it has done throughout its existence. The average width after the closure of New Inlet—and prior to the construction of the groin—was approximately 3,925 feet (1,200 meters) based on available historical data. If Oregon Inlet were to revert to its historical migration patterns, and assuming that there is no substantial erosion on the Bodie Island spit, the Hatteras Island shoulder might migrate south nearly 2,000 feet (610 meters) to assume an average width similar to those prior to the construction of the terminal groin. This trend could be accelerated by storm events, which historically have caused Oregon Inlet to widen and shallow. Conversely, if this period were relatively storm-free, this reversion to a wider inlet could be mitigated. Thus, the period for this to occur is unpredictable because of the randomness of such events. Figure 3-6 illustrates the predicted short-term migration of Hatteras Island. It first shows the history of movement for the Bodie Island shoulder, the mid-point of Oregon Inlet, and Hatteras Island from 1930 to the current time. It shows that Hatteras Island stopped its movement when the terminal groin was constructed. After the completion date of a bridge in the Pamlico Sound Bridge Corridor, the figure shows first the potential short-term movement of Hatteras Island as described above.

As stated previously, the movement of Oregon Inlet's gorge has created difficulty for the USACE in maintaining the navigation channel beneath the Bonner Bridge's navigation span. The removal of the terminal groin would pose new challenges for maintaining the current navigation channel because of probable inlet migration.

Long-Term Impacts of the Removal of the Terminal Groin

If the terminal groin is removed, Oregon Inlet eventually would be expected to revert to historical migration trends. Since the closure of New Inlet (and in the 15 years prior to its closure), Oregon

Inlet followed a nearly linear migration pattern with the exception of the Ash Wednesday Storm in 1962. The Hatteras Island shoulder has migrated in a linear (i.e., constant) fashion over the last 70 years (within ± 1,500 feet [460 meters] for a 3,000-foot [910-meter] total range). With the exception of the migration after the Ash Wednesday Storm of 1962, the entire inlet has migrated linearly (within ± 1,700 feet [520 meters] for a 3,400-foot [1,040-meter] total range). Figure 3-6 depicts the linear migration of Oregon Inlet over the last 70 years.

Figure 3-6 also illustrates the potential migration of Oregon Inlet through 2090. It illustrates the potential short-term and maximum long-term location of the north end of Hatteras Island, assuming both the retention of the terminal groin and a return to past trends should the groin be removed.

The movement south of the northern end of Hatteras Island over the life of a Pamlico Sound bridge would be the greatest if the groin were removed shortly after the bridge opens. For example, if the groin were removed 3 years after the bridge opens, and Oregon Inlet began to migrate in the same linear fashion as it did before the groin was built, then 50 years after the bridge opens, the Oregon Inlet shoulders of Hatteras and Bodie islands would migrate between 4,600 and 8,000 feet (1,400 and 2,440 meters) south. (This range represents the ± 1,700-foot [520-meter] deviation.) After 75 years, Oregon Inlet would have migrated between 6,900 and 10,300 feet (2,100 and 3,140 meters) south. (This range also represents the ± 1,700-foot [520-meter] deviation.) This example represents a "worst-case" situation, which is prudent to consider in long-range planning. It does not represent FHWA's and NCDOT's present expectations or their intent to remove the groin. If USFWS officials ask the NCDOT to remove the groin following completion of the demolition and removal of Bonner Bridge, the NCDOT and representatives of the USFWS would assess the impacts of groin removal in a separate environmental study, as needed, prior to any final decision to remove the terminal groin.

If Oregon Inlet were to migrate between 6,900 and 10,300 feet (2,100 and 3,140 meters) south, it would be located in the north pond of the Refuge, which is also just behind the Canal Zone hot spot. If Oregon Inlet migrates in a southward direction, another channel, Davis Channel (Slough), could become the more-preferred flow pattern, since it is already substantially deep and a notable connection of Oregon Inlet to Pamlico Sound. According to a 2001 survey, Davis Channel depths reached almost -50 feet (-15 meters) NAVD-88.

Relation of Hatteras Island Change to Navigation Zone Location with the Pamlico Sound Bridge Corridor

One navigation zone would be built for a bridge in the Pamlico Sound Bridge Corridor to serve boats passing through Oregon Inlet. The location of the zone would be determined in coordination with the USACE and the US Coast Guard. The USACE currently maintains the Oregon Inlet/Old House navigation channel. As discussed above, movement of Oregon Inlet over the life of the bridge could shift the natural channel gorge to the Davis Channel area. This eventuality would be addressed in conversations with the USACE. The NCDOT's goal would be to place the navigation zone of the bridge in a location that facilitates channel maintenance over the full life of the bridge.

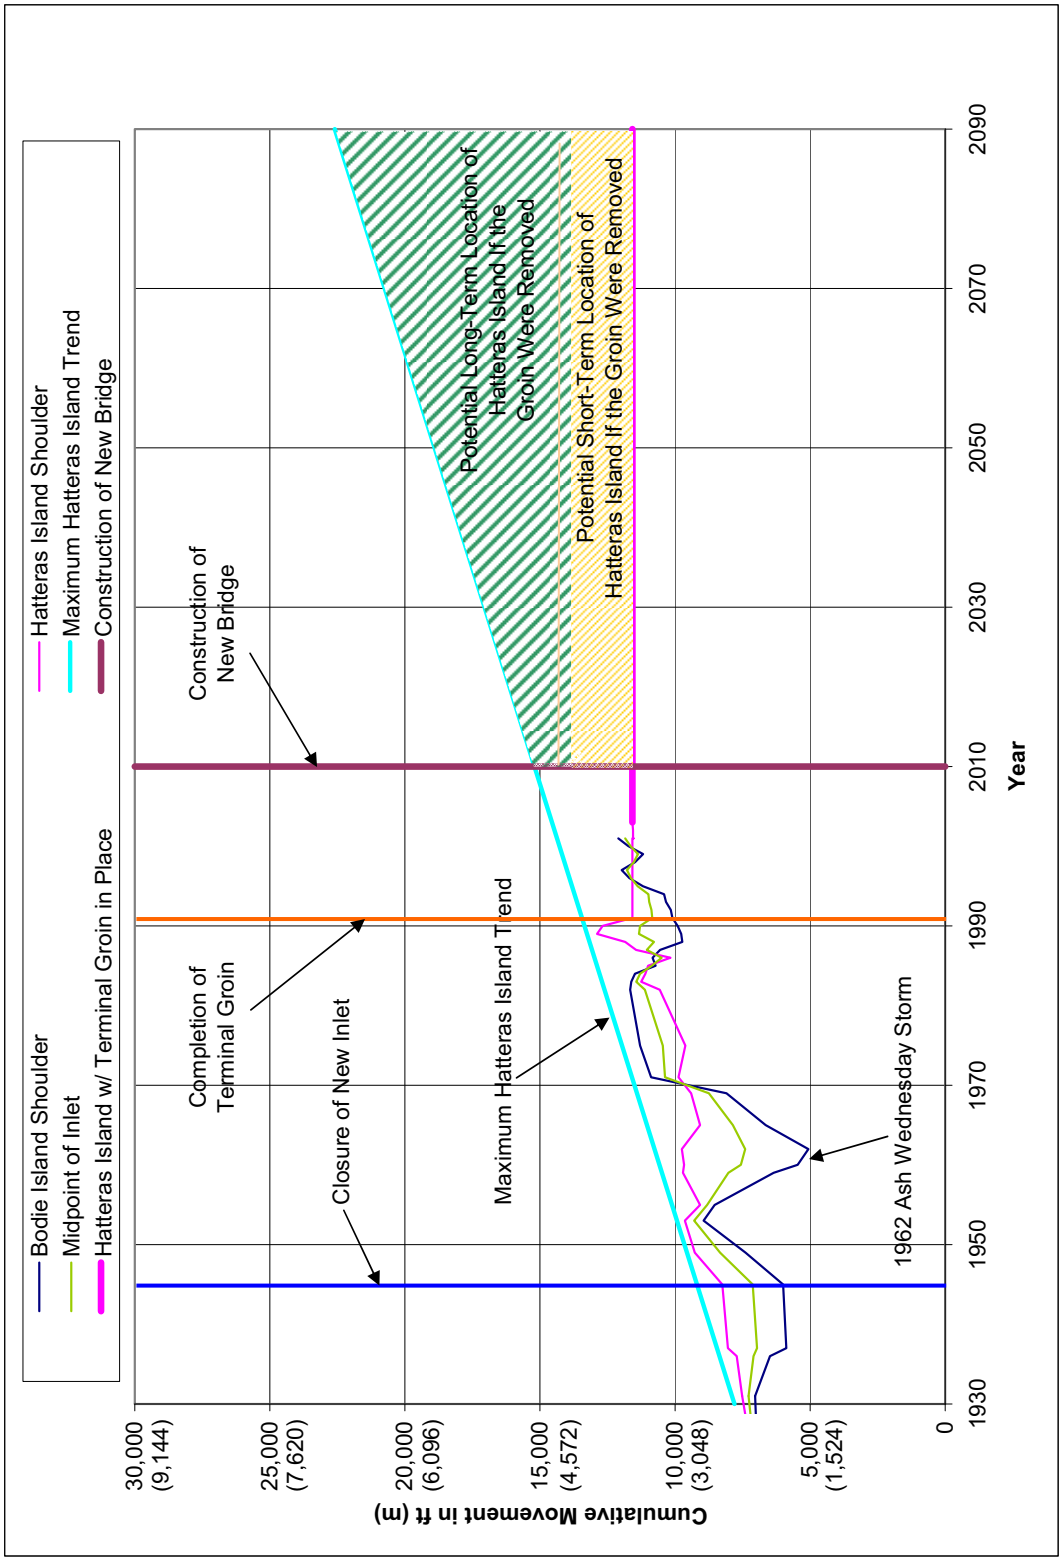


Figure 3-6. Historic and Predicted Migration of Oregon Inlet

3.7 Natural Systems

3.7.1 Geology, Topography, and Soils

The project area is in the northeastern portion of the lower Atlantic Coastal Plain physiographic region of North Carolina. Fluvial processes and a history of alternating shoreline advance and retreat have shaped the geomorphology of the region. Predominate geographic features in the project area are the Pamlico Sound, the Outer Banks, and Oregon Inlet. Marine-derived sediments underlie the entire Pamlico Sound. Above the Pamlico Sound's crystalline bedrock are layers of sedimentary rock deposited during periods of high sea level. The most recent sedimentary layers, dating from the Upper Miocene to the Pliocene, are composed of primarily quartz sand, shell, and silt.

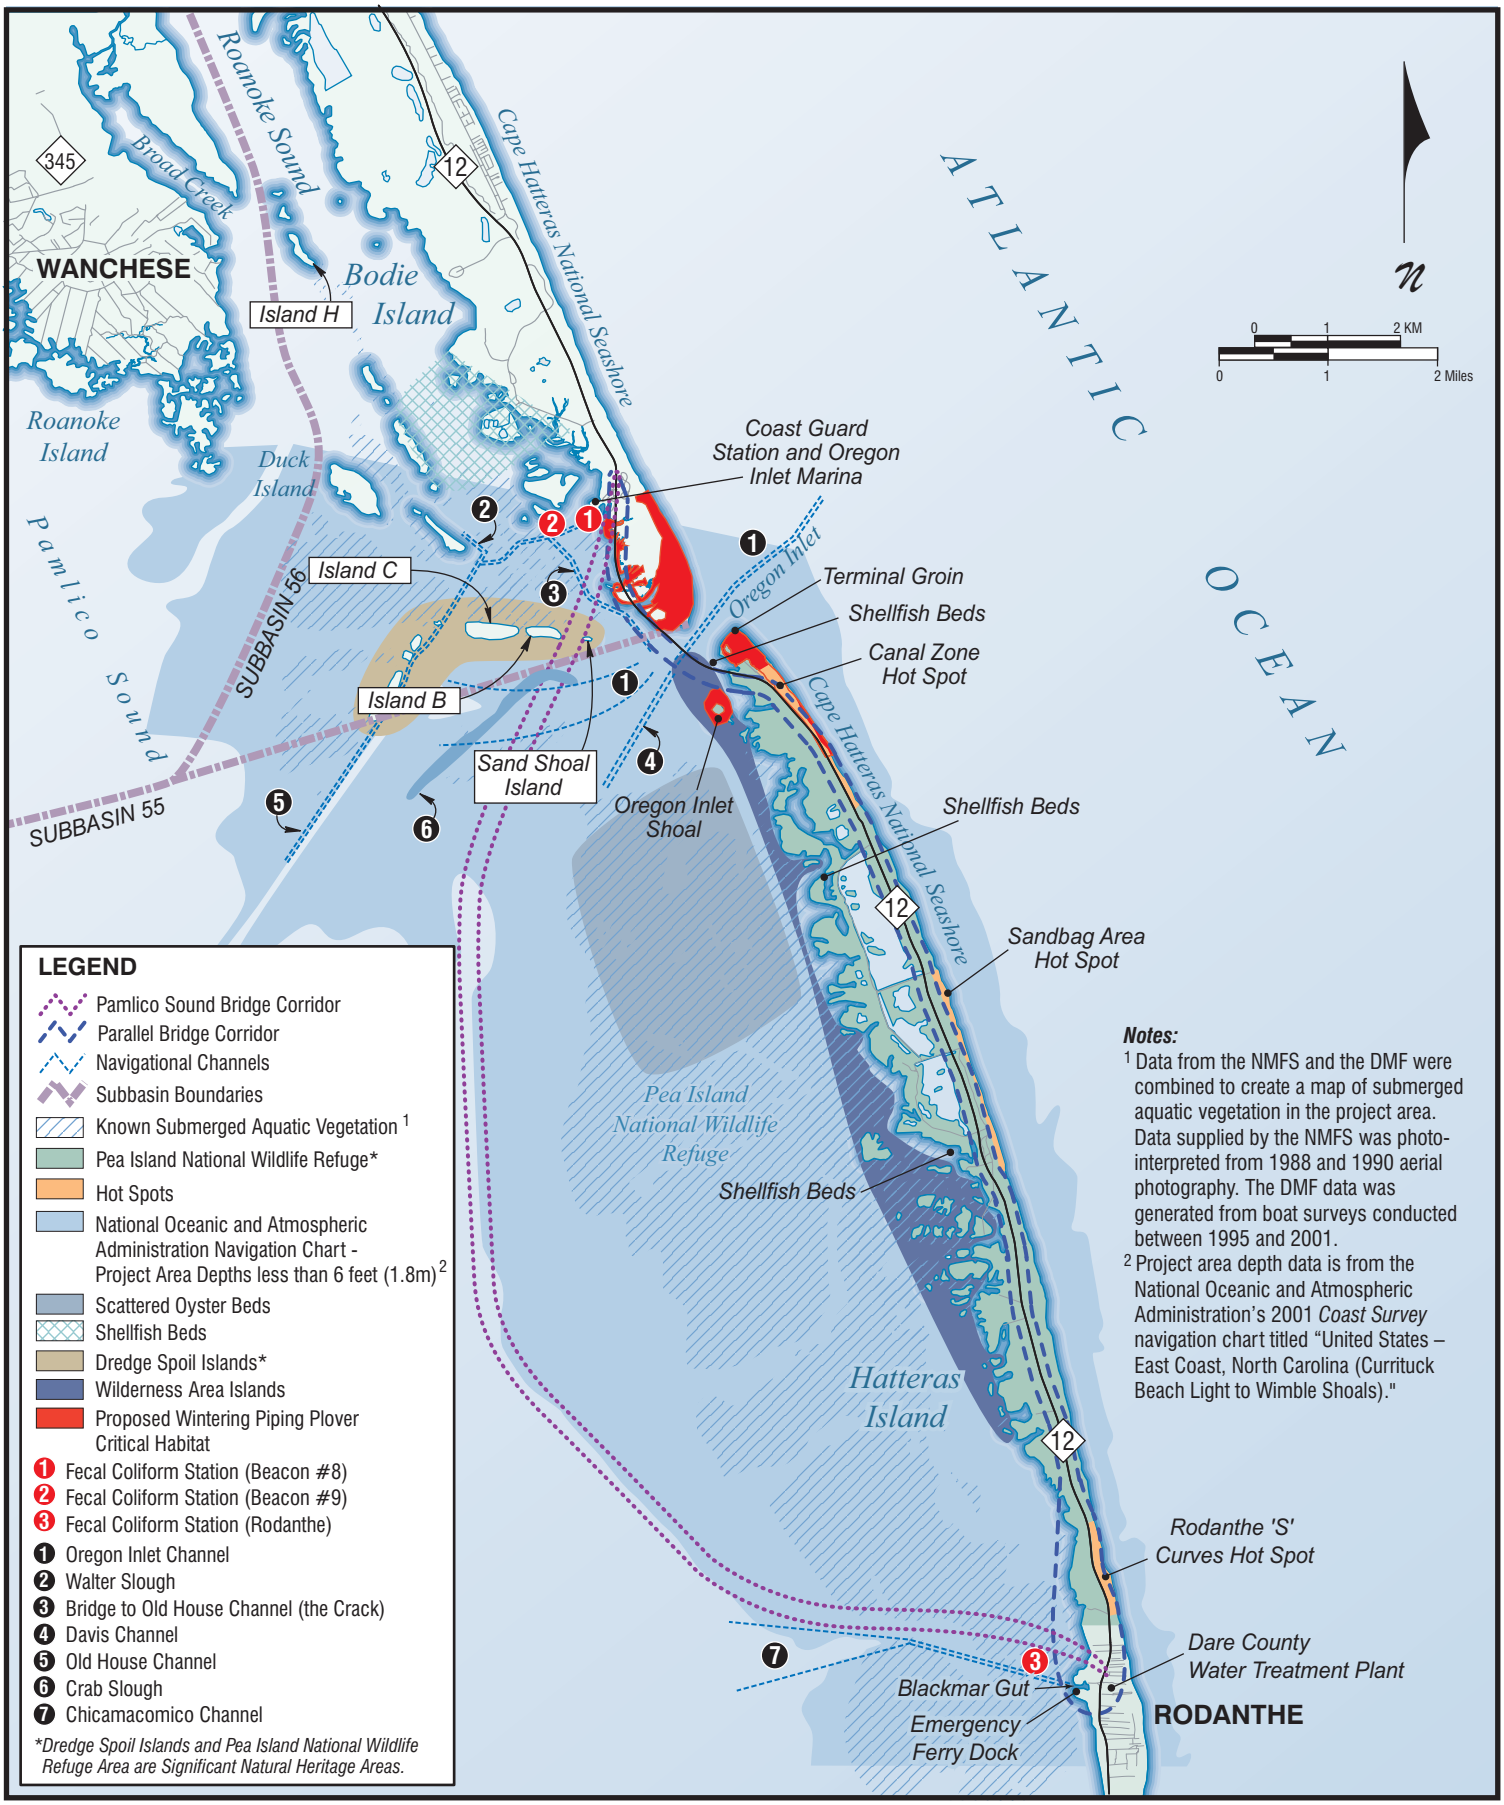
The North Carolina Outer Banks comprise a dynamic barrier island system formed by wind and wave action. Underlying the sandy ridges that make up the barrier islands are layers of limestone, sand, and clay. The topography of the Outer Banks consists of nearly level and gently sloping land draining into the Pamlico Sound and Atlantic Ocean.

Oregon Inlet connects the Atlantic Ocean and the Pamlico Sound. The inlet was formed in 1846 after a severe storm. Since that time, the location and size of Oregon Inlet have changed (see Section 3.6.2.1).

Based on the US NRCS (formerly US Soil Conservation Service) survey of Dare County (Soil Conservation Service, 1992), the soils found on the Atlantic Ocean side of the Outer Banks are mostly well-drained sand beaches with sparse vegetation, while soils found on the Pamlico Sound side are sandy but poorly drained and heavily vegetated. Two soil associations are present in the project area, the Newhan-Duckston-Corolla and Hobonny-Carteret-Currituck associations. Soil associations are defined as landscapes that exhibit distinctive proportional patterns of soils and consist of one or more major soils and at least one minor soil. The soils within an association generally vary in slope, depth, stoniness, drainage, and other characteristics (Tant, 1996). Descriptions of the soil series associated with the Newhan-Duckston-Corolla and Hobonny-Carteret-Currituck associations are presented in Table 3-16.

3.7.2 Surface Waters and Water Quality

The primary water bodies in the project area are Pamlico Sound and Oregon Inlet (see Figure 3-7). Also present within the project area are tidal creeks along the sound side of the Outer Banks.



3.7.2.1 Surface Water Characteristics

The Pamlico Sound is a large estuarine water body separating the Outer Banks and the mainland of North Carolina. Water depth in the project area generally is less than 4 feet (1.2 meters), except in deeper channels and the western boundary of the project area (at the location of the Pamlico Sound Bridge Corridor) where depths greater than 6 feet (1.8 meters) are common. The Pamlico Sound drains several water bodies, but those closest to the project area are the Albemarle Sound (see Figure 1-1) and the Roanoke Sound (see Figure 3-7), both north of Oregon Inlet. Wind tides are one of the primary forces controlling hydrologic fluctuations within the Pamlico Sound. (Personal communication, May 20, 2003, Dr. Stan Riggs, East Carolina University.) Water levels also are influenced by lunar tides, but lunar effects diminish with distance from

Table 3-16. Soils Series Occurring within the Bonner Bridge Project Area

Map Unit	Soil Series	Slope	Drainage	General Characteristics
BnD*	Beaches-Newhan Complex	0-25%	Excessively Drained	Permeability is very rapid with daily tidal flooding. These soils are on long narrow areas of coastal beaches, typically on the ocean side of the Outer Banks and on inlets and islands.
CeA*	Carteret Sand	0-2%	Very Poorly Drained	These soils are frequently flooded by tides and have a seasonal high water table 3 feet (0.9 meter) above to 1 foot (0.3 meter) below the soil surface. These soils are found in broad marshes on the sound side of the Outer Banks.
CoB*	Corolla Fine Sand	0-6%	Moderately Well-Drained or Somewhat Poorly Drained	Permeability is very rapid, and the seasonal high water table is 1.5 feet (0.5 meter) to 3 feet (0.9 meter) below the soil surface. These soils occur in troughs and on flats between dunes on the Outer Banks.
CrB*	Corolla-Duckston Complex	0-6%	Moderately Well-Drained	Permeability is very rapid and the seasonal high water table is 1.5 feet (0.5 meter) to 3 feet (0.9 meter) below the soil surface. These soils are commonly found directly inland from some of the frontal dunes.
DtA*	Duckston Fine Sand	0-2%	Poorly Drained	Permeability is very rapid above the water table. The seasonal high water table is at or near the soil surface and fluctuates somewhat in relation to the tides. These soils are on flats and in slight depressions on the Outer Banks.
DwE	Dune Land-Newhan Complex	2-40%	Excessively Drained	Permeability is very rapid, and the available water capacity is very low. The seasonal high water table is more than 6 feet (1.8 meters) below the soil surface. These soils are found along the Outer Banks situated parallel to the ocean.
NhC*	Newhan-Corolla Complex	2-40%	Excessively Drained	Permeability is very rapid, and the available water capacity is very low in the Newhan soil. The seasonal high water table is more than 6 feet (1.8 meters) below the soil surface. These soils are found on the Outer Banks lying parallel to the ocean, often forming a transition zone between the soils along the ocean and the wet, flat soils adjacent to the sound. The soils are typically 60 percent dune land and 35 percent Newhan soils.
NeC*	Newhan Fine Sand	0-10%	Excessively Drained	Permeability is very rapid. The seasonal high water table is more than 6 feet (1.8 meters) below the soil surface. These soils are found on dunes on the Outer Banks. It is within the salty spray zone and supports salt-tolerant vegetation.
PsB	Psamments	0-6%	-	This map unit consists of areas where the surface layer and most of the subsoil have been removed. It includes borrow pits, fill and dredge areas, and areas of landfill. Soil properties within this map unit vary significantly.

*Occurs on Hydric Soils list, Gregory, 2001.

WATER BODIES AND OTHER NATURAL RESOURCE-RELATED FEATURES

Figure 3-7

Oregon Inlet. Similarly, waters near Oregon Inlet have high flushing rates compared to waters farther away.

The project area is in the Pasquotank River basin. The NCDENR's DWQ has divided North Carolina's major drainage basins into sub basins. The project area falls within two sub basins:

- The southern end of Bodie Island is in sub basin 56.
- The southern portion of Oregon Inlet south to Rodanthe is in sub basin 55 (NCDENR, 2002).

Surface waters within the Refuge portion of the project area include four manmade ditches, a manmade pond, three manmade impoundments (North Pond, New Field Pond, and South Pond), and estuarine waters directly associated with the Pamlico Sound.

The DWQ assigns further water body classifications according to the best usage of waters; water quality standards are applied according to classification. The waters of the Pamlico Sound from Croatan and Roanoke Sounds to Sandy Point south to Stumpy Point Bay to the northeast tip of Ocracoke Island are classified as SA waters (Class A salt waters) (15A North Carolina Administrative Code [NCAC] 2B.0317); therefore, all of the project area's waters are classified as SA waters. SA waters are suitable for commercial shellfishing and all other tidal saltwater uses including:

- Swimming;
- Primary and secondary recreation; and
- The propagation of aquatic life.

All Class SA waters have a supplemental classification of High-Quality Waters (15A NCAC 2B.0100). Water quality standards for SA waters are listed in the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2005).

3.7.2.2 Water Quality

For the project area, there is little recent comprehensive water quality data available from the DWQ, and there are no ambient water quality monitoring stations within or near the project area. Overall, water quality in sub basin 55 is considered to be high (NCDENR, 2002). In 1989, DWQ (at that time known as the Division of Environmental Management of the North Carolina Department of Environment, Health, and Natural Resources) conducted a synoptic water quality study of the Albemarle/Pamlico system. A total of 33 water quality parameters were sampled from the surface, photic zone, bottom, and throughout the water column. Two locations sampled near Oregon Inlet (Pamlico Sound near channel marker R 4M14 "PA" and Roanoke Sound at channel marker G "9") indicated that the parameters tested were within state standards and expected ranges. Specific chemical and biological data for these locations are listed in the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2005).

The USACE conducted elutriate testing during its Manteo (Shallowbag) Bay project to determine if dissolved constituents are released from the bottom sediments when agitated. Of the numerous parameters tested, it was found that only mercury and zinc were at elevated levels. It was stated, however, that the rapid reduction of these metals to existing background levels is typical

(USACE, 1980a,b,c). The continual inflow and outflow of waters through Oregon Inlet reduces the chances of any permanent water quality problems near Oregon Inlet.

The NCDENR's Division of Environmental Health, Shellfish Sanitation Section monitors fecal coliform levels at one station in the Oregon Inlet Marina and a second station at Rodanthe. A third station, at Fishing Center channel, was monitored until 2000 (see Figure 3-7). Yearly average coliform levels from 1997 to 2007 range from 1.8 to 8.1 per 100 milliliters, and in no year did fecal coliform levels exceed the standards for SA waters (14/100 ml). The specific levels measured from 1997 to 2002 at the three locations are listed in the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2008).

Point source and non-point source pollution within the project area are limited. There is only one facility requiring a National Pollution Discharge Elimination System Permit. The facility is the reverse osmosis water treatment plant in Rodanthe that is permitted to discharge low salinity wastewater into the Pamlico Sound at Blackmar Gut (see Figure 3-7). Local non-point source pollution is typical of developed areas and generally is in the form of stormwater runoff.

Additional potential pollution sources are incidental spills of petroleum and exhaust emissions associated with the heavy boat traffic in the area. While significant agricultural activity is not found locally, the project area is influenced by basin-wide land use, including runoff from agricultural and livestock operations.

3.7.2.3 NC 12 Runoff

Current highway runoff from Bonner Bridge is directly discharged to Oregon Inlet via scuppers along either side of the main span of the bridge. Runoff from the rest of NC 12 in the project area is discharged into the road's unpaved shoulders and ditches.

NC 12 in the project area, including Bonner Bridge, was constructed prior to the development of federal (e.g., Clean Water Act) and state stormwater regulations; therefore, no stormwater controls or best management practices (BMPs) are in place. Water quality impacts associated with current NC 12 operations are mainly related to the potential for contamination of receiving surface waters by runoff from impervious roadway surfaces. NC 12 in the project area contains approximately 47 acres (19 hectares) of impervious roadway surface.

Common sources of highway pollutants include vehicles, dustfall, and precipitation. Other potential sources of runoff pollutants include highway maintenance (e.g., sanding and deicing), accidental oil and/or gas spills, and losses from accidents (FHWA, 1996). Common highway runoff constituents and their corresponding primary sources are presented in Table 3-17.

Generally, heavy metals, nutrients, organic compounds, and particulates are the primary constituents of concern in highway runoff. The water quality impacts from each of these constituent groups are described in further detail below:

- Heavy Metals. Heavy metals (specifically copper, lead, and zinc) are typically the priority pollutants of concern in highway runoff (Transportation Research Board, 1993). The main concern surrounding presence of heavy metals is related to their long-term accumulation in bottom sediments and animal tissue. Increased impervious surfaces and vehicle use can result in elevated concentration of heavy metals in surface waters.

Table 3-17. Common Highway Runoff Constituents and Primary Sources

Constituent	Primary Sources
Particulates	Pavement wear, vehicles, atmosphere, maintenance, snow/ice abrasives, sediment disturbance
Nitrogen, Phosphorus	Atmosphere, roadside fertilizer use, sediments
Lead	Leaded gasoline (auto exhaust), tire wear, lubricating oil and grease, bearing wear, atmospheric fallout
Zinc	Tire wear, motor oil, grease
Iron	Auto body rust, steel highway structures, engine parts
Copper	Metal plating, bearing and bushing wear, moving engine parts, brake lining wear, fungicides and insecticides use
Cadmium	Tire wear, insecticide application
Chromium	Metal plating, engine parts, brake lining wear
Nickel	Diesel fuel and gasoline, lubricating oil, metal plating, brake lining wear, asphalt paving
Manganese	Engine parts
Bromide	Exhaust
Cyanide	Anticake compound used to keep deicing salt granular
Sodium, Calcium	Deicing salts, grease
Chloride	Deicing salts
Sulfate	Roadway beds, fuel, deicing salts
Petroleum	Spills, leaks, blow-by motor lubricants, antifreeze, hydraulic fluids, asphalt surface leachate
Polychlorinated Biphenyls (PCBs), pesticides	Spraying of highway right-of-ways, atmospheric deposition, PCB catalyst in synthetic tires
Pathogenic bacteria	Soil litter, bird droppings, trucks hauling livestock/stockyard waste
Rubber	Tire wear
Asbestos	Clutch and brake lining wear

Source: Kobringer, 1984

- Nutrients. Nutrients also are a substantial constituent present in highway runoff and are deposited via atmospheric deposition and fossil fuel combustion by vehicles. High levels of nitrogen and phosphorus can cause algae blooms, which ultimately lead to a decrease in dissolved oxygen as the algae decompose.

- Organic Compounds. Organic compound sources include exhaust, fuel, lubricants, and asphalt and have been detected in higher concentrations along roadways. Organic pollutants are of particular concern because of their ability to accumulate to concentrations that are harmful to aquatic organisms (e.g., impacts to growth and reproduction and mortality). Chemical oxygen demand (COD) is a common indicator of the amount of organic compounds in surface water and represents the mass of oxygen consumed per liter of solution (mg/L).

- Particulates. Particulates and solid materials are a primary concern in highway runoff with an increase in impervious surfaces because of their ability to capture and transport other pollutants. For example, phosphorus and various metals readily adsorb to solids, particularly fine particles. These pollutants are often released when introduced to water, which in turn affects the water quality of the receiving water body and has the potential to reduce the variety and abundance of aquatic life.

The accumulation of pollutants on highway surfaces is affected by various factors including the following (Gupta et al,. 1981):

- Traffic characteristics (volume, speed, braking);
- Climate conditions (precipitation, wind, temperature);
- Maintenance (sweeping, mowing, repair, deicing, herbicides);
- Land use (residential, industrial, commercial, rural);
- Percent pervious and impervious areas;
- Vehicle characteristics (age and condition);
- Anti-litter laws and vehicle emission regulations;
- Use of special additives in vehicle operation;
- Vegetation types on highway right-of-way; and
- Accidental spills.

Traffic characteristics, atmospheric deposition, and site-specific conditions (e.g., land use, highway surface, and maintenance practices) are often considered as the major contributing factors to pollutant constituents and concentrations.

3.7.3 Biotic Communities

The conceptual term "biotic community" is used to designate a distinct assemblage of plants and animals. The following sections describe each biotic community within the project area in terms of its characteristic physical environmental factors, biota, and functional role. Biotic communities within the project area were delineated through interpretation of July 12, 2002, color aerial photographs and field verification during May and June 2003. Project area biotic community delineations were also conducted during field investigations in March 2003 and May and June 2004 in association with NCDOT Transportation Improvement Program (TIP) Project Nos. R-3116D and R-3116E/F, as well as during further field investigations associated with this project (TIP No. B-2500) during November and December 2004. Additional habitat and delineated wetland mapping was completed in June 2005 based on the expanded project area selected for detailed evaluation. Biotic communities of the project area are presented in Figure E-2a through Figure E-2h in Appendix E. Approximate acreage (hectares) for each community is presented in Table 3-18. Plant species listed represent species observed on-site as well as species associated with natural communities, as described by Shafale and Weakley (1990), which are

Table 3-18. Biotic Communities Within the Project Area

Biotic Community[1]	Acres (hectares)			
	Bodie Island	Rodanthe	Pea Island National Wildlife Refuge	Total
Open water	251.30 (101.70)	149.54 (60.52)	615.62 (249.13)	1,016.46 (411.35)
Beach	0.80 (0.30)	19.36 (7.83)	235.18 (95.17)	255.34 (103.32)
Dunes	3.70 (1.50)	17.29 (6.99)	408.71 (165.40)	429.70 (173.90)
Wetland man-dominated	9.00 (3.64)	4.15 (1.68)	0.38 (0.15)	13.53 (5.47)
Upland man-dominated	21.90 (8.86)	130.52 (52.82)	109.79 (44.43)	262.21 (106.11)
Wetland salt shrub/grasslands	3.90 (1.58)	14.47 (5.86)	270.98 (109.66)	289.35 (117.10)
Upland salt shrub/grasslands	0.00 (0.00)	9.71 (3.93)	55.49 (22.46)	65.20 (26.39)
Wetland maritime grassland	3.20 (1.29)	23.79 (9.63)	32.89 (13.31)	59.88 (24.23)
Upland maritime grassland	0.00 (0.00)	0.00 (0.00)	50.92 (20.61)	50.92 (20.61)
Wetland overwash	0.00 (0.00)	0.00 (0.00)	34.36 (13.91)	34.36 (13.91)
Upland overwash	0.00 (0.00)	0.00 (0.00)	37.52 (15.18)	37.52 (15.18)
Wetland maritime shrub thicket	6.70 (2.71)	18.26 (7.39)	176.17 (71.29)	201.13 (81.39)
Upland maritime shrub thicket	8.90 (3.60)	37.62 (15.22)	312.59 (126.50)	359.11 (145.32)
Wetland reed stand	0.00 (0.00)	3.95 (1.59)	11.41 (4.62)	15.36 (6.22)
Upland reed stand	0.00 (0.00)	0.00 (0.00)	2.85 (1.15)	2.85 (1.15)
Salt flat	0.00 (0.00)	0.00 (0.00)	0.16 (0.06)	0.16 (0.06)
Brackish marsh	1.30 (0.53)	0.00 (0.00)	2.24 (0.91)	3.54 (1.44)
Smooth cordgrass	27.30 (11.05)	5.93 (2.40)	8.82 (3.57)	42.05 (17.02)
Wetland black needlerush	24.70 (10.00)	3.51 (1.42)	226.10 (91.50)	254.31 (102.92)
Upland black needlerush	0.00 (0.00)	0.00 (0.00)	7.82 (3.16)	7.82 (3.16)
TOTAL	**362.70 (146.78)**	**438.10 (177.30)**	**2,600.00 (1,052.17)**	**3,400.80 (1,376.25)**

NOTE: Hectares calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

[1] Biotic community acreages calculated based on 363-acre (146.8-hectare) wetland delineation area confirmed by the USACE on February 2, 2005.

found in the project area. Wildlife listings are from a review of literature for the project area as well as species records documented from the area. The appendices of the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2005) contain complete lists of vascular flora referenced in this section, as well as species lists and scientific names for fish and wildlife documented or expected in the project area.

The following biotic communities/habitats were identified within the project area:

- Open water;
- Beach;
- Dunes;
- Wetland man-dominated;
- Upland man-dominated;
- Wetland salt shrub/grasslands;
- Upland salt shrub/grasslands;
- Wetland maritime grassland;
- Upland maritime grassland;
- Wetland overwash;
- Upland overwash;
- Wetland maritime shrub thicket;
- Upland maritime shrub thicket;
- Wetland reed stand;
- Upland reed stand;
- Salt flat;
- Brackish marsh;
- Smooth cordgrass;
- Wetland black needlerush; and
- Upland black needlerush.

The man-dominated communities and reed stands are the result of human disturbance. Open water and sound areas exist naturally within the project area; however, some open water areas in the Refuge, such as ditches, a manmade pond, and freshwater impoundments, are the result of human disturbance within the project area. The remaining communities are considered "natural" systems: beach, dunes, overwash, salt shrub/grasslands, maritime grassland, maritime shrub thicket, salt flat, black needlerush, smooth cordgrass stands, and brackish marsh.

The habitat categories are described below. In selecting these categories, heavy reliance was placed on the plant communities identified and described by the North Carolina Natural Heritage

Program (NCNHP) classification and the 1993 Bonner Bridge Replacement DEIS (Shafale and Weakley, 1990; McCrain, 1988). McCrain identified ten plant communities. Although some of these communities were retained for the current study, various stages of community development and physiographic differences between Bodie Island and Hatteras Island required further breakdown and additional categories provided by NCNHP classifications. Previous community descriptions of this area and adjacent habitats include Quay (1959), who defined 16 major habitats of the Seashore, and Cooper (1963), who described five basic groups of vegetation types from the Bodie Island marshes. Brown (1959) and Burke (1962) each provided general floristic descriptions of the Outer Banks. Additional comparisons were made with updated plant community descriptions in the International Classification of Ecological Communities (NatureServe, 2002). Based on the expanded project area, community classifications have been modified in some instances to better reflect field observations. Biotic communities are further described below.

3.7.3.1 Open Water

Marine open water, as defined by Quay (1959), includes the waters of Oregon Inlet, Atlantic Ocean, and Pamlico Sound. Waters of the Atlantic Ocean abut the eastern project boundary. The project area is situated in North Carolina DWQ Sub basin 03-01-55 and US Geologic Survey (USGS) Hydrologic Unit 03020105.

Open water is also used to describe the estuarine waters directly associated with Pamlico Sound within the project area, as well as creeks, ponds, ditches adjacent to NC 12, freshwater impoundments, and intertidal mudflats. Some open water areas, such as the pond in the northern section of Rodanthe, also provide mudflat habitat in drought or low water conditions. Ditches (Pauls Ditch and other unnamed manmade ditches), ponds, and the impoundments do not have DWQ Index Numbers.

Pamlico Sound is a shallow, coastal lagoon that is separated from the ocean by the Outer Banks. The Sound is approximately 60 miles (96.8 kilometers) long and 15 to 30 miles (24.2 to 48.4 kilometers) wide. The maximum depth is about 22 feet (6.7 meters); the average depth is less than 15 feet (4.6 meters). The watershed is approximately 12,500 square miles (32,518 square kilometers) (Epperly and Ross, 1986). Because of restricted tidal flow, the mean tidal range is generally less than 0.5 feet (0.15 meters), with no designated times of high water and low water except near the inlets. Currents are weak and depend mainly on the direction and velocity of the wind, not upon lunar tidal oscillation. Because of intense vertical mixing, sound waters are vertically homogeneous; that is, salinity, temperature, and dissolved oxygen show little or no vertical stratification. Water temperatures closely follow air temperatures, normally ranging from around 39ºF (4ºC) in January to 84ºF (29ºC) in July. The salinity ranges from moderate to high; near Oregon Inlet, the salinity can range from 6 to 32 parts per thousand. (Personal communication, August 30, 1990, Beth Burns, NCDENR-DMF.)

Extensive seagrass (also known as submerged aquatic vegetation or SAV) beds occur near Oregon Inlet and throughout shallow portions of Pamlico Sound. These seagrass beds form a complex and important ecosystem. Submerged beds of eelgrass (*Zostera marina*), shoalgrass (*Halodule wrightii*), and widgeongrass (*Ruppia maritima*) exist together and separately. Seagrasses can occur in isolated patches and as extensive beds. The importance of seagrass systems to estuarine ecology has been widely recognized (Thayer et al., 1975, 1979, 1981; Zieman, 1975; Thayer and Phillips, 1977; Fonseca et al., 1979; McRoy and Helfferich, 1980; Ferguson et al., 1981; Zimmerman and Minello, 1984; Weinstein, 1985). Numerous studies have documented seagrass habitats as important nursery areas for many fish species (Adams, 1976;

Thayer et al., 1979; Weinstein and Heck, 1979; Orth and Heck, 1980; Miller and Dunn, 1980; Stoner, 1980; Homziak et al., 1982; Epperly and Ross, 1986; Kenworthy et al., 1988; McMichael and Peters, 1989; Noble and Monroe, 1990). Data from the National Marine Fisheries Service (NMFS) and the DMF were combined to create a map of SAV in the project area (see Figure 3-7). Data supplied by the NMFS was photo-interpreted from 1988 and 1990 aerial photography. The DMF data was generated from boat surveys conducted between 1995 and 2001. The dynamic nature of the area around Oregon Inlet results in ephemeral habitats, particularly in shallow water and shoreline areas. A survey conducted by NCDOT in the fall of 2007 found that only 25 percent of the SAV habitat contained SAV. SAV can be affected by a variety of factors including light availability, water temperature, sediment composition, wave energy, tidal range, and a variety of other factors. These factors may influence the location and the amount of SAV from year to year.

Other vascular plants are absent from this community; however, phytoplankton and seaweed frequently are found where sufficient light penetration and suitable habitat occur. Species of *Ulva*, *Fucus*, *Gracilaria*, *Cladophora*, *Polysiphonia*, and *Ectocarpus* typically are seen along the shore or intertidal zone.

Loons, grebes, shearwaters, cormorants, scoters, mergansers, gulls, and terns are birds commonly encountered in open water habitat (Parnell et al., 1989). The bottlenose porpoise (*Tursiops truncatus*) is a common marine mammal of the near-shore ocean. Marine sea turtles periodically encountered include the loggerhead sea turtle (*Caretta caretta*), Atlantic green turtle (*Chelonia mydas*), Kemp's ridley sea turtle (*Lepidochelys kempi*), and leatherback turtle (*Dermochelys coriacea*). (Personal communication, July 16, 1990, L. K. Gantt, USFWS.) Sea turtle abundance and seasonality are influenced by both currents and water temperature (Schwartz, 1989). Hawksbill sea turtles (*Eretmochelys imbricata*) also can be found in the project area, though they are very rarely encountered.

3.7.3.2 Beach

These bare, transitional areas between the open water and upland terrestrial community are characterized by sand flats. They typically consist of a dry berm zone beyond the mean high tide line, an intertidal zone that is regularly covered by tidal action, and a subtidal zone that exists below the low tide mark, including the top and beachside of dunes. This community undergoes frequent, natural disturbance and is typically void of vegetation, however, it can be characterized by a small number of species and the dominance of succulents. Within the project area, sea kale (*Cakile harperi*) and seaside pennywort (*Hydrocotyle bonariensis*) dominate, with small occurrences of beach pea (*Strophostyles helvola*), beach spurge (*Euphorbia polygonifolia*), and sea rocket (*Cakile edentula*) situated along the highest wrack or seaweed lines. Substantial erosion of the beachside of the dunes in the Refuge occurred during Hurricane Isabel in 2003. Along the southern end of Bodie Island near the campground, the beach within the project boundary is approximately 400 feet (122.0 meters) wide; the widest point within the project boundary at Rodanthe is approximately 700 feet (213.4 meters) wide.

The brown pelican (*Pelecanus occidentalis*), double-crested cormorant (*Phalacrocorax auritus*), American oystercatcher (*Haematopus palliatus*), and numerous gulls and terns often are found resting or feeding at the water's edge. Shorebird surveys conducted by the USFWS in the Refuge estimate that typically 3,600 to 4,800 shorebirds might use the beach during the peak of migration (USFWS, 1988a). The North Carolina Audubon Society estimates that greater than 10,000 shorebirds use the Refuge (North Carolina Audubon Society, Unpublished USFWS data, 2003). Also, loggerhead sea turtles frequently use the beach/foredune habitats for nesting.

3.7.3.3 Dunes

Dunes in the project area are landward and generally parallel to the beach community. This community undergoes constant gradual movement and is subject to abrupt changes during storms, particularly during strong northeasterly winds. The primary dune system developed as winds moved intertidal sands landward. Mobile sand was trapped by vegetation and by fences in many areas. Although dunes do occur naturally, most dunes along the Seashore are not natural features. Under the direction of the NPS, sand fencing (more than 600 miles [967.7 kilometers]) was erected to create a protective, continuous barrier dune between 1936 and 1940. Additional stabilization, including planting efforts by the NPS, also was undertaken in the 1950s. Presently, a continuous mass of vegetation blankets most of the dunes (Dolan, 1973).

Extensive dunes exist immediately north and south of the campground on the southern end of Bodie Island, while a narrow band of dunes can be found parallel to NC 12 on Hatteras Island. A non-continuous band of dunes that is broken by development exists along the eastern shore of Rodanthe.

Dominant vegetation observed include sea oats (*Uniola paniculata*), sea kale, pennywort, croton (*Croton punctatus*), American beach grass (*Ammophila breviligulata*), silver panic grass (*Panicum amarum*), saltmeadow cordgrass (*Spartina patens*), broom sedge (*Andropogon virginicus*), seaside goldenrod (*Solidago sempervirens*), and beach elder (*Iva imbricata*). Other common species include seaside evening primrose (*Oenothera humifusa*), fire wheel (*Gaillarida pulchella*), prickly pear (*Opuntia drummondii*), hoary plantain (*Plantago virginica*), English plantain (*P. lanceolata major*), yellow thistle (*Cirsium horridulum*), blackberry (*Rubus cuneifolius*), and cyrillo (*Stellaria media*). Species less frequently encountered included ground cherry (*Physalis viscosa* spp. *maritima*), beach spurge, sand spur (*Cenchrus tribuloides*), and beach bean (*Strophostyles helvola*). The vine layer consists of catbrier (*Smilax auriculata* and *bona-nox*), arrowleaf morning glory (*Ipomeoea saggittata*), fox grape (*Vitis aestivalis*), and beach pea. Small patches of red cedar (*Juniperus silicicola*) and silverling (*Baccharis halimifolia*) are sparsely distributed throughout the dune community.

Birds frequently encountered on the dune fields include the red-winged blackbird (*Agelaius phoeniceus*), boat-tailed grackle (*Quiscalus major*), and savannah sparrow (*Passerculus sandwichensis*) (Parnell et al., 1989).

Mammals found in the dune community include Virginia opossum (*Didelphis virginiana*), eastern cottontail (*Sylvilagus floridanus*), house mouse (*Mus musculus*), gray fox (*Urocyon cinereoargenteus*), and the raccoon (*Procyon lotor*). Common reptile and amphibians include eastern hognose snake (*Heterodon platyrhinos*), black racer (*Coluber constrictor*), six-lined racerunner (*Cnemidophorus sexlineatus*), and Fowler's toad (*Bufo woodhousei*).

3.7.3.4 Man-Dominated Areas (Wetland and Upland)

This community is typical of areas where man's structures or activities prevent natural plant succession. Roadside margins, areas around the campground, the US Coast Guard Station on Bodie Island, NC 12, the Oregon Inlet Marina and Fishing Center, parking areas and access roads, developed areas associated with the Refuge Visitor Center, USFWS buildings, and residential development in Rodanthe all receive regular mowing and pruning. Consequently, plant growth patterns are modified and species composition stays relatively stable and limited to low-growing, herbaceous species. Much of the original vegetative communities were altered in areas where permanent structures were constructed within Rodanthe. Extensive residential and commercial development has occurred in Rodanthe creating the need to define further this

community type into wetland and upland man-dominated areas. Wetland man-dominated areas occur in areas that sustain wetland hydrology, vegetation, and soils, but are maintained by regular mowing, such as the wetlands around the Oregon Inlet Marina and Fishing Center. A variety of grasses, sedges, and rushes are common around these areas with seaside pennywort, yellow thistle, various asters (*Aster* spp.), hoary plantain, English plantain, panic grass (*Panicum* spp.) spadeleaf (*Centella asiatica*), frog fruit (*Lippia nodiflora*), fire wheel, white-top sedge (*Dichromena colorata*), and various grasses (*Poaceae* spp. and *Festuca* spp.) frequently encountered.

Birds commonly sighted around roadsides include cattle egret (*Babulcus ibis*), killdeer (*Charadrius vociferus*), and northern mockingbird (*Mimus polyglottos*). Species frequently sighted nesting or foraging in this community include barn swallow (*Hirundo rustica*), purple martin (*Progne subis*), American robin (*Turdus migratorius*), European starling (*Sturnus vulgaris*), and red-winged blackbird (Parnell et al., 1989).

Mammals commonly found near these man-dominated areas include the red bat (*Lasiurus borealis*) seen foraging overhead, the marsh rabbit (*Sylvilagus palustris*) along highway edges, and the Norway rat (*Rattus norregicus*) and the house mouse near buildings and dumps (Parnell et al., 1989).

3.7.3.5 Salt Shrub/Grasslands (Wetland and Upland)

This is often a transitional community between small, high areas of salt marshes (smooth cordgrass and black needlerush) and the more stable maritime shrub thicket. This community can have an open to closed canopy and can include up to 50 percent shrubs and grasses. Dense vegetation, generally dominated by saltmeadow cordgrass with a mixture of wetland and mesic species creates a community with high diversity. This community is co-dominated by salt-tolerant shrubs such as marsh elder (*Iva frutescens*), silverling, and wax myrtle (*Myrica cerifera*). Other common shrub species are yaupon (*Ilex* vomitoria), saltwater false willow (*Baccharis angustifolia*), red bay (*Persea borbonia*), and black cherry (*Prunus serotina*). Vines present in this community include catbrier (*Smilax bona-nox*) and Japanese honeysuckle (*Lonicera japonica*). Blackberry and poison ivy (*Toxicodendron radicans*) are also found within the salt shrub/grassland community. Herbaceous species include black needlerush (*Juncus roemerianus*), poison ivy, seaside evening primrose (*Oenotherna humifusa*), marsh pink (*Sabatia campanulata*), seaside goldenrod, and sea ox-eye (*Borrichia frutescens*). Salt shrub/grassland community occurs predominately on the sound side of the project area.

The fauna of salt shrub/grasslands is similar to those species found in maritime grassland (Section 3.7.3.6) and the maritime shrub thicket (Section 3.7.3.8), representing a diverse assemblage of animals.

3.7.3.6 Maritime Grassland (Wetland and Upland)

The maritime grassland community is within the dune swales and along sand flats with elevations near the water table, which is normally just below the surface. The maritime grassland community also occurs in old overwash terraces and relic marsh areas that have been filled in with sand. This interdunal community is protected from salt spray and contains a variety of grassland vegetation. Most swales in the project area are seasonally flooded or saturated wetlands in which vegetation is usually dense and diverse. These areas are co-dominated by American bulrush (*Scirpus americanus*), saltmeadow cordgrass, and sand rush (*Fimbristylis spadicea*). Other common species include saltgrass, spadeleaf, smartweeds (*Polygonum* spp.),

buttonweed (*Diodia virginiana*), fimbristylis (*Fimbristylis spp.*), pink muhlenbergia (*Muhlenbergia filipes*), Virginia broomsedge (*Andropogon virginicus*), and black needlerush.

Isolated pockets of maritime dry or upland grassland are excessively drained at the surface, with occasional overwashing by salt water in severe storms. Overwash sand deposits may temporarily bury the vegetation, but the dominant species are well adapted to recover quickly from such natural disturbance. There is generally moderate to dense herbaceous cover in upland maritime grasslands and are typically dominated by saltmeadow cordgrass and those species found in the wet maritime grassland. The maritime grassland community transitions into dune grass, maritime shrub, and brackish and salt marsh communities.

A large marshy interdunal swale adjacent to a trailer park in Rodanthe is included with this community. This particular swale is lower in elevation and flooded more regularly than other swales in the project area. Vegetation in this swale contains a mixture of dominants including common cattail (*Typha latifolia*), black needlerush, saw grass (*Cladium jamaicense*), wool-grass (*Scirpus cyperinus*), swamp rose mallow (*Hibiscus moscheutos*), and seashore mallow (*Kosteletskya virginica*). Other species include salt-marsh bulrush (*Scirpus robustus*), arrowleaf morning glory (*Ipomoea sagittata*), climbing hempweed (*Mikania scandens*), and royal fern (*Osmunda regalis* var. *spectabilis*).

This typically wet transition zone supports a variety of animals species found in both the drier dune communities and the wet marsh areas.

3.7.3.7 Overwash (Wetland and Upland)

The overwash community consists of areas that have been recently overwashed by saltwater and sand from severe storm events, and areas in which NC 12 abuts the dunes and sand removal from the roadway is performed on a regular basis. As previously mentioned, a majority of the overwash areas observed at the time of site reconnaissance in 2005 occurred during Hurricane Isabel in September 2003. Sand deposition in most of the overwash areas varies from 6 to 24 inches (6.2 to 61.0 centimeters). In general, overwash areas contain less than 10 percent vegetation.

3.7.3.8 Maritime Shrub Thicket (Wetland and Upland)

Maritime shrub thicket typically occurs landward of the salt shrub/grassland community or behind dune fields where it is protected from salt spray and harsh winds. It is characterized by low shrubs that usually are entangled with vines. Maritime shrub thicket is found predominantly on the west side of NC 12 along the sound side within the Rodanthe project area, especially behind the Liberty service station on the west side of NC 12. This community also borders the northwest side of the US Coast Guard Station on Bodie Island, as well as the Oregon Inlet Marina and Fishing Center.

Variations in elevation within the project area have created the need to break this community type into wetland and upland shrub thickets. Wetland shrub thickets occur predominantly adjacent to sound side marsh communities and in some interdunal areas. Upland shrub thickets primarily occur on higher elevations such as on the backside of stabilized sand dunes and dune swales. A large upland shrub thicket exists on the southern edge of the campground on Bodie Island.

Shrubs that dominate the higher elevations include wax myrtle, yaupon (*Ilex vomitoria*), red cedar (*Juniperus virginiana*), bayberry (*Myrica pennsylvanica*), black cherry (*Prunus serotina*), live oak (*Quercus virginiana*), and loblolly pine (*Pinus taeda*). Vegetation common in lower areas

are silverling, marsh elder, and wax myrtle. Common vines include poison ivy, catbrier (*Smilax bona-nox*), pepper-vine (*Ampelopsis arborea*), and muscadine (*Vitis rotundifolia*).

A diverse community of animals occurs in the maritime shrub thicket. Common resident birds include Carolina wren (*Thryothorus ludovicianus*), gray catbird (*Dumetella carolinensis*), northern cardinal (*Cardinalis cardinalis*), and boat-tailed grackle (Parnell et al., 1989). Mammal species that are common in shrub thickets (especially on Bodie Island) include the Virginia opossum, least shrew (*Cryptotis parva*), gray fox, and raccoon. Quay (1959) noted that the southeastern five-lined skink (*Eumeces inexpectatus*), eastern glass lizard (*Ophisaurus ventralis*), ribbon snake (*Thamnopyhis sauritus*), eastern hognose snake, black racer, and eastern king snake (*Lampropeltis getulus*) are found in shrub thickets.

3.7.3.9 Reed Stand

This community exists in small to large patches on Hatteras Island. Giant reed (*Phragmites communis*) occurs on both sides of NC 12 at the northern tip of Hatteras Island and at the emergency ferry dock in Rodanthe adjacent to areas of wetland maritime shrub thicket. A large stand occurs in the northern portion of the Rodanthe area where a wetland maritime grassland community was disturbed by a man-dominated walkway and gazebo. Characteristic of previous disturbance, this opportunistic species often is associated with wetter shrub thickets.

While providing only limited food resources, reed stands do offer cover and roosting habitat for birds such as grackles. Marsh rice rat (*Oryzomys palustris*), raccoons, muskrats (*Ondatra zibethicus*), and nutria (*Myocaster coypus*) also are found in reed stands.

3.7.3.10 Salt Flat

The salt flat community consists of a shallow depression in which salt is concentrated by the evaporation of seawater. Salt flat communities are sparse in vegetation and are dominated by plants with high salt tolerances, such as glasswort (*Salicornia spp.*), saltgrass (*Distichlis spicata*), and sea ox-eye (*Borrichia frutescens*). Salt flat communities transition into salt marshes and brackish marshes. This community is found within the Refuge on both the sound and ocean sides of the black needlerush communities.

3.7.3.11 Brackish Marsh

Brackish marsh is similar to other saltmarsh communities and consists of mixed stands of rushes (*Juncus* spp.*)*, saw grass, smooth cordgrass, and poison ivy. Sparse shrub vegetation also can be found in brackish marsh communities. This community is present on southern Bodie Island near the current terminus of Bonner Bridge and north of the Oregon Inlet Marina and Fishing Center. Cattails (*Typha* spp.) also are found in brackish marsh, especially on the sound side of Bodie Island.

Red-winged blackbirds and marsh wrens (*Cistothorus palustris*) are common in brackish marsh, as are mammals typical of emergent estuarine wetland habitats.

3.7.3.12 Smooth Cordgrass

This emergent wetland community, like the black needlerush community, is within the intertidal zone. It occurs in pure stands along the sound side of both Hatteras and Bodie islands and on the southern tip of Bodie Island. Along the fringe of intertidal creeks, the community receives regular tidal inundation and provides stability for the shoreline margins. Spoil islands in the

sound often are fringed with smooth cordgrass (*Spartina alterniflora*) where the land is regularly flooded. This low marsh community typically provides nursery areas for various species of shrimp, crabs, and marine and estuarine fish.

Commonly encountered fauna include clapper rails (*Rallus longirostris*) and seaside sparrow (*Ammodramus maritimus*). Marsh rice rat, raccoons, muskrats, and nutria are also common.

3.7.3.13 Black Needlerush (Wetland and Upland)

The black needlerush community occurs primarily along the margins of the Pamlico Sound and extends east, eventually grading into the salt shrub, salt shrub/grassland, and maritime grassland community. Within the intertidal zone, this emergent wetland community is composed of pure stands of needlerush. Large stands are found throughout the southern tip of Bodie Island where unconsolidated sand has accreted, resulting in the irregular flooding that facilitates the establishment of this common marsh species. A large patch of needlerush also exists just north of the emergency ferry dock at Rodanthe. Organic soils underlay this community, and the regular input of nutrients from lunar tides makes this a very productive community. Smooth cordgrass often is found fringing the lower edges of this community. At higher elevations, this marsh community is almost entirely dominated by black needlerush; however, other species such as cattail (*Typha angustifolia*), common reed, swordgrass, salt meadow hay (*Spartina patens*), and various other rushes are common throughout this community. Other species occurring along the fringe of the marsh community, such as, silverling, marsh elder, sea-ox-eye, sea myrtle, saltmeadow cordgrass, and sand rush become co-dominant. Several dredge spoil islands in the sound are dominated by this community, as is the fringe of intertidal creeks on Hatteras Island. Large stands of pure needlerush also occur on the sound side of Bodie Island.

Areas that are designated as upland black needlerush result from several factors. There are substantially disturbed locations that are not jurisdictional wetlands. Also, areas contain needlerush as the dominant vegetation but are affected by overwash, including less than major hurricane storm events, and are not jurisdictional wetlands. These areas are not denoted as overwash since overwash communities are defined, in general, as communities with less than 10 percent vegetative coverage. Over time these communities are anticipated to transition into upland communities.

The tidal marsh functions to provide inorganic and organic nutrients to adjacent aquatic communities, as well as to protect the sound side of the barrier island from wind and wave action. Many aquatic organisms depend on the tidal marsh. As a source of primary production, this community aids in forming the base of estuarine food webs.

Commonly encountered fauna include rails and wading birds. Marsh rice rat, raccoons, and nutria also are common.

3.7.4 Wetlands and Open Water Habitat

3.7.4.1 Definitions

Wetlands are defined by the USACE (33 *Code of Federal Regulations* [CFR] 328.3) and the US Environmental Protection Agency (USEPA, 40 CFR 230.3) as "those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions." Wetlands possess three essential characteristics: hydrophytic vegetation, hydric

soils, and wetland hydrology. All three characteristics must be present to be identified as wetland (USACE Environmental Laboratory, 1987). The USACE and the USEPA are federal agencies charged with regulating the discharge of dredged or fill material in jurisdictional wetlands and open waters under Section 404 of the Clean Water Act of 1977, as amended.

Open water habitats are permanently flooded lands below the deepwater boundary of wetlands. These habitats include environments where surface water is permanent and often deep, so that water, rather than air, is the principal medium within which the dominant organisms live (Cowardin et al., 1979). Open water habitats of the project area are found primarily in association with the surface water of Pamlico Sound, Oregon Inlet, and the Atlantic Ocean.

Coastal wetlands are marshy areas subject to regular or occasional flooding by lunar or wind tides. These wetlands play a vital role in the productivity of estuaries. Coastal wetland protection in North Carolina is limited to marsh areas in its 20 coastal counties. The DCM administers state laws and regulations that provide protection for Areas of Environmental Concern (including coastal wetlands). The two main state legislative acts are CAMA and the North Carolina Dredge and Fill Act of 1969.

Ten wetland communities occur within the project area: wetland man-dominated, wetland salt shrub/grasslands, wetland maritime grassland, wetland overwash, wetland maritime shrub thicket, reed stand, salt flat brackish marsh, smooth cordgrass stands, and black needlerush. Approximate wetland habitat boundaries are depicted in Figure E-2a through Figure E-2h in Appendix E. Descriptions of these wetland communities are in Section 3.7.3 and Table 3-19. Jurisdictional wetlands were delineated using the three-parameter approach prescribed in the *1987 Corps of Engineers Wetlands Delineation Manual* (USACE Environmental Laboratory, 1987). Supplementary technical literature describing the parameters of hydrophytic vegetation, hydric soils, and wetland hydrologic indicators was also utilized.

3.7.4.2 Classification of Wetlands and Open Water Areas

Classification of Section 404 wetlands and the open water areas in Table 3-19 is based on *Classifications of Wetlands and Deepwater Habitats of the United States* (Cowardin et al., 1979).

The marine system consists of the near-shore ocean and the associated beach. Near-shore ocean is characterized by subtidal conditions and possesses an unconsolidated sandy bottom. Submerged aquatic vegetation (SAV) is comprised of seagrasses and also comprises a portion of estuarine subtidal wetlands in Pamlico Sound. Permanently flooded seagrass beds consist of rooted vascular species such as eelgrass, shoalgrass, and widgeongrass. The SAV provides vital nursery habitat for fish, shellfish, and other animal species. The SAV habitats in the waters of the Albemarle-Pamlico Sound, especially along the eastern periphery of the sound, are the most productive habitats for fish and shellfish (Ferguson et al., 1989). Overall, the importance of seagrasses and their role in many coastal ecosystems have been extensively documented.

The beach is an intertidal unconsolidated shore that is irregularly flooded from storms and spring high tides. The landward limit of this system extends to where tidal inundation stops on the beach during the high spring tides and to the seaward limit of the estuarine system within Oregon Inlet (approximated by the line of demarcation in Figures E-2a through E-2h in Appendix E). The open water areas also are classified as wetlands by the USFWS. Oregon Inlet and the nearby Pamlico Sound are both estuarine subtidal wetlands that possess an unconsolidated sandy bottom.

Table 3-19. Classification of Jurisdictional Waters and Wetlands in the Project Area by Community Type

Biotic Community Classification[1]	USFWS Classification[2]	Approximate Acres (hectares)[3]
Open water		
• Near-shore ocean	Marine, subtidal, unconsolidated bottom, sand, subtidal	NA
• Submerged aquatic vegetation (SAV)	Estuarine, subtidal, aquatic bed, rooted vascular, sand, subtidal	600.00 (242.81)
• Inlet and sound	Estuarine, subtidal, unconsolidated bottom, sand, subtidal	NA
• Impoundments	Lacustrine, littoral, aquatic bed, rooted vascular, artificially flooded, brackish, diked impoundments	290.00 (117.36)
Man-dominated[4]	NA	NA
Salt/shrub grasslands	Estuarine, intertidal, emergent, persistent, irregularly flooded; and estuarine, intertidal, shrub-scrub, broad-leaved evergreen, irregularly flooded	289.35 (117.10)
Maritime grassland	Palustrine and estuarine, intertidal, emergent, persistent, irregularly flooded	59.88 (24.23)
Overwash[5]	NA	NA
Maritime shrub thicket	Estuarine, intertidal, shrub-scrub, broad-leaved evergreen, irregularly flooded; and Palustrine, shrub-scrub, broad-leaved evergreen	201.13 (81.39)
Reed stand	Palustrine, emergent, persistent, seasonally flooded/saturated	15.36 (6.22)
Salt flat	Estuarine, subtidal, unconsolidated bottom	0.16 (0.06)
Brackish marsh	Estuarine, intertidal, emergent, persistent, irregularly flooded	3.54 (1.44)
Smooth cordgrass	Estuarine, intertidal, emergent, persistent, regularly flooded	42.05 (17.02)
Black needlerush	Estuarine, intertidal, emergent, persistent, irregularly flooded	254.31 (102.92)

[1] The project area for the natural systems analysis is the area shown on Figure E-2a through Figure E-2h in Appendix E.

[2] Equivalent USFWS classification based on *Classifications of Wetlands and Deepwater Habitats of the United States* (Cowardin et al., 1979).

[3] Determined from CZR, Incorporated biotic communities mapping; near-shore ocean and inlet and sound areas were not quantified because these resources are pervasive and extend well beyond the project's area of effect.

[4] Disturbed and not a natural area so is not classified.

[5] Biotic community includes less than 10 percent vegetation cover and is not applicable to wetland classification.

The CAMA defines coastal wetlands as areas that contain at least one of the following species: smooth cordgrass, black needlerush, glasswort, salt grass, sea lavender (*Limonium carolinianum*), bulrush, saw grass, cattail, saltmeadow grass, and giant cordgrass. Within the project area, extensive coastal wetlands are present. The most abundant estuarine wetland class within the project area is the persistent emergent wetland, which consists of erect, rooted herbaceous hydrophytes. The communities included in this category are black needlerush, smooth cordgrass, and brackish marsh on Bodie Island and Hatteras Island. The frequency and duration of tidal flooding control the floristic composition in these communities; smooth cordgrass is restricted to regularly flooded areas; irregularly flooded areas are dominated by black needlerush and brackish marsh.

A second common wetland class in the project area is the estuarine shrub-scrub and/or emergent wetland. This class is dominated by woody vegetation, typically less than 20 feet (6.1 meters) tall or persistent herbaceous vegetation (Cowardin et al., 1979). This class commonly includes broad-leaved evergreen shrubs and trees that are found in the low shrub/grassland and maritime shrub thicket communities. Wet maritime grasslands and salt shrub/grasslands that are seasonally flooded and remain saturated fall under this classification.

Most of the wetland areas are on the west side of NC 12 and are part of a large estuarine system that extends along the eastern boundary of Pamlico Sound. The wetland boundary associated with the estuarine system of Pamlico Sound crosses in and out of the project area. Therefore, separate wetland areas are part of a larger system whose wetland boundary does not always occur within the project area.

The beach, dune community, man-dominated areas, and isolated salt shrub/grassland, maritime grassland, overwash, reed stand, and maritime shrub thickets comprise the upland communities within the project area. Additional isolated areas designated as upland black needlerush located in disturbed overwash areas are not jurisdictional wetlands.

Physical marking of the wetland boundary was not permitted within the Refuge. The wetland boundaries were mapped at the time of the wetland delineation using a Trimble Global Positioning System (GPS) backpack unit with sub-meter accuracy. The USACE has performed a jurisdictional determination of the project area, including areas on Bodie Island and Hatteras Island.

Two soil associations are present in the project area, the Newhan-Duckston-Corolla and Hobonny-Carteret-Currituck associations. Soil associations are defined as landscapes that exhibit distinctive proportional patterns of soils and consist of one or more major soils and at least one minor soil. The soils within an association generally vary in slope, depth, stoniness, drainage, and other characteristics (Tant, 1996). Field verification along with examination of soils, vegetation, and hydrology on Bodie Island and Hatteras Island, substantiated that most uplands are found on beaches, dunes, and in man-dominated areas occurring on Beaches-Newhan Complex, Newhan fine sand soils or Duneland-Newhan complex. These generally are upland areas lacking the hydrology and soils required for wetlands. Other soils that are not considered hydric include the dredge spoil placed on a point of land west of the Oregon Inlet Marina and the area underlying the Oregon Inlet Marina and Fishing Center buildings and parking lots.

A few isolated patches of upland are dominated by dunes, man-dominated areas and shrub thickets. These areas exist on one of these soils:

- A Newhan-Corolla complex soil;
- Newhan fine sand; or

- Corolla fine sand.

These soils also have inclusions of Duckston hydric soils within the numerous wet depressions and troughs. These wet interdunal swales and small shrub thickets have sandy, saturated soils and are high in organics. Soil samples taken during field verification indicate hydric soils throughout most of these communities. Characteristic soil colors from these wet swales were 10 YR 5/1 and contained organics (obtained from Munsell Soil Color Charts, 1988).

Hydric soils are defined as soils that are saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions that favor the growth and regeneration of hydrophytic vegetation (Cowardin, et al., 1979). Hydric soils cover approximately 70 percent of the study area and include the Beaches portion of the Beaches-Newhan complex, Carteret sand, the Duckston portion of the Corolla-Duckston complex, and Duckston fine sand (Gregory, 1996). Soil types that are known to contain hydric inclusions occupy an additional 30 percent of the project area and include Corolla fine sand, Newhan fine sand, and the Newhan-Corolla complex (Gregory, 1996). Less than 1 percent of the project area is covered by non-hydric soils and includes Dune land-Newhan complex and Psamments (Gregory, 1996).

Functional values associated with wetlands are flood control, improving water quality, shoreline stabilization, groundwater recharge and discharge, and aquatic food chain support, as well as important wildlife habitat. The aesthetic, recreational, educational, and economic value of wetlands also contribute to the concern for wetland habitat.

3.7.4.3 Intertidal Zone

The area of beach that is exposed between high tide and low tide is referred to as the intertidal zone. The difference between elevation of high and low tide for Cape Hatteras is small (0.0 to 6.5 feet [0.0 to 2.0 meters]), and is dependent on the stage of the moon. However, a vertical change in ocean elevation may result in flooding or exposure of a varying amount of area depending on the slope of the beach. The intertidal zone within the project area is classified as M2US2 (Marine, Intertidal, Unconsolidated Shore, Sand) in the wetlands and deepwater habitats classification system (Cowardin et al., 1979). As a navigable water of the United States, the intertidal zone falls under the jurisdiction of Section 404 of the Clean Water Act, and therefore falls under the jurisdiction of the USACE and the USEPA.

3.7.5 Unique and Rare Habitats

The Wilderness Act of 1964 established the National Wilderness and Preservation System. Under the 1964 Act, the US Secretary of the Interior must review the suitability for preservation of all designated Wilderness areas in the NWRS. Included under designated Wilderness areas are roadless islands within the NWRS. Therefore, in 1974 the USFWS recommended for Wilderness status "recognizable" islands on the sound side of the Refuge (USFWS, 1975). Most of the proposed unnamed islands identified in the 1975 report were just southwest of the southernmost freshwater pond and within 1 mile (1.6 kilometers) of Hatteras Island. Also recommended for Wilderness designation and within the project area is the Oregon Inlet Shoal, which is west of the northern end of Hatteras Island. The islands are dominated in the low marsh by black needlerush, marsh elder, bulrush, and spikerushes (*Elocharis sp.*); there is saltmarsh cordgrass along the island perimeter. In total, approximately 180 acres (72.9 hectares) were proposed as Wilderness. While a final decision was never made as to the islands' status, the USFWS manages them as if they are Wilderness areas. Although some of these islands might have changed since 1975, the

criterion for Wilderness status is the same and applies to currently recognizable islands on the sound side of the Refuge. The approximate locations of these islands are outlined in Figure 3-7.

The NCNHP has identified Significant Natural Heritage Areas (SNHA) throughout the state. The NCNHP compiles the NCDENR list of Significant Natural Heritage Areas as required by the Nature Preserve Act (North Carolina Geodetic Survey [NCGS] Chapter 113-A-164 of Article 9A). The list is based on the program's inventory of natural diversity in the state (NCDENR, 1997). Natural areas are evaluated on the basis of the occurrences of rare plant and animal species, rare or high-quality natural communities, and geologic features. The global and statewide rarity of these elements and the quality of their occurrence at a site relative to other occurrences determines a site's significance rating. SNHA designation is used for locations of ecological significance or rarity. The NCNHP has further classified these SNHAs by priority ranking, which takes into account the relative value of each SNHA.

Two SNHAs are found in the project area. The first are the dredge spoil islands around Oregon Inlet, which are important nesting and feeding areas for colonial waterbirds. The islands closest to the Pamlico Sound Bridge Corridor are Island B, Island C, and Sand Shoal Island (see Figure 3-7). These dredge spoil islands, which were recommended for Wilderness designation, were given a priority ranking of B meaning that these islands contain the "best" occurrences of colonial waterbird nesting islands found in the state; "best" usually is restricted to the top five examples. The island closest to the Parallel Bridge Corridor is Oregon Inlet Shoal, which is west of the northern boundary of the Refuge and west of the Parallel Bridge Corridor. Oregon Inlet Shoal, which was also recommended for Wilderness designation, developed from natural shoaling because of interactions of the Oregon Inlet Shoal Channel, the Oregon Inlet Channel, and several less defined channels in the area. (Personal communication, July 20, 2005, Dennis Stewart, Wildlife Biologist, USFWS.)

The second SNHA is the Refuge. Because of its value to migratory waterfowl, the Refuge was given a priority ranking of A, meaning that the site contains the "best" occurrences of migratory birds known to exist anywhere in the United States; "best" usually is defined as the top five sites. This refuge is made up of 5,843 acres of barrier island beach, dunes, salt flats, and salt marsh. An additional proclamation area of approximately 25,000 acres (10,117 hectares) is adjacent and west of the Refuge in the Pamlico Sound. A wide variety of wading birds, waterfowl, and shorebirds utilize the Refuge, including the endangered piping plover. The beaches provide nesting habitat for sea turtles such as the threatened green and loggerhead sea turtles.

3.7.6 Water Resources, Fisheries, and Wildlife

3.7.6.1 Water Resources

DWQ classifies surface waters of the state based on their intended best uses. Unnamed tributaries receive the same best usage classification as the named streams into which they flow. Waters within the project area, have been classified as Class SA waters, denoting suitability for commercial shell fishing and all other tidal saltwater uses (NCDENR, 2002). In addition, Class SA waters are also suitable for all Class SC and SB uses, which include primary and secondary recreation and aquatic life propagation and survival.

High Quality Waters (HQWs) are waters that are rated as excellent based on biological and physical/chemical characteristics through monitoring or special studies, native and special trout waters, primary nursery areas, critical habitat areas, water supply watersheds classified as Water Supply Watersheds (WS-I or WS-II), and all Class SA waters. The waters in the project area have been classified as Class SA waters; therefore, these waters are HQWs. No WS-I or WS-II

or Outstanding Resource Waters occur within the project area. The Pamlico Sound at Hatteras Island has been identified as a Habitat Area of Particular Concern (HAPC) in the Fisheries Management Plan for the Southeast and Caribbean (NMFS, 1999). HAPCs are subsets of essential fish habitat (EFH).

The Ambient Monitoring System (AMS) is a network of stream, lake, and estuarine water quality monitoring stations strategically located for the collection of physical and chemical water quality data. The type of water quality data or parameters collected is determined by the waterbody's classification and corresponding water quality standards. Data from the AMS determines the "use-support" status of waterbodies, meaning how well a waterbody supports its designated uses. Surface waters (streams, lakes, or estuaries) are rated as *fully supporting*, *partially supporting*, or *not supporting*. These terms refer to how well the surface water supports the classified uses thereof. The DWQ did not sample benthic macroinvertebrates, fish communities, fish tissue, or ambient water quality in this sub basin. Therefore, the DWQ relies on information from the North Carolina Division of Environmental Health, local water treatment plant (WTP) operators, and county health departments for determining "use support" ratings in this sub basin. The majority of the waters of the Pamlico Sound are rated as *fully supporting* for aquatic life, primary and secondary recreation, and shellfish harvesting. Blackmar Gut, which abuts the southwestern project boundary, is rated as *not supporting* for secondary recreation and shellfish harvesting. The Atlantic coastal waters are rated as *partially supporting* for fish consumption and *fully supporting* for primary recreation (NCDENR, 2002).

Over 460 miles (740.3 kilometers) of freshwater streams and rivers are within the Pasquotank River Basin. Of these freshwater resources, more than 60 percent are considered impaired because of low dissolved oxygen and high turbidity, which are attributed to nonpoint source runoff from agricultural land use (NCDENR, 1994). Within the project area's sub basins, some areas are closed to shellfish harvesting because of unacceptably high levels of fecal coliform bacteria believed to be associated with urban runoff, septic tanks, and marinas. There are no areas in which shellfish harvesting is restricted within the project area (NCDENR, 2002).

The effort to develop a method to assess water quality based on macroinvertebrates in estuarine waters began in late 1990. An estuarine biotic index (EBI) designed for Florida was modified to create the North Carolina EBI, which more closely reflects taxa and tolerances in North Carolina and can accurately rank sites of different water quality. However, the DWQ has not collected macroinvertebrate data in this sub basin and cannot assign a rating to these waters (NCDENR, 2002).

3.7.6.2 Fish and Shellfish

The estuarine waters of Pamlico Sound provide habitat for a diversity of aquatic life. Larvae of various marine and estuarine fish, invertebrates, and zooplankters graze upon large phytoplankton populations dominated by various diatoms. Many of the shallow creeks, bays, extensive marshes, and submerged aquatic vegetation beds function as nursery areas for finfish and shellfish species. Estuarine-dependent fish, crustaceans, and other organisms use the sound as a passage way to spawning areas or feeding grounds. The waters are used by resident estuarine species, as well as transient anadromous (move from the ocean to rivers to spawn), catadromous (move from freshwaters to the ocean to spawn), and marine species. The DMF conducts juvenile trawl sampling from waters adjacent to Oregon Inlet. During these surveys, more than 100 different species of fish and shellfish have been captured in the immediate vicinity of the project area. The Walter Slough area behind Bodie Island is particularly productive. (Personal communication, August 1, 1990, Beth Burns, NCDENR-DMF.) In 1990 to 2002 juvenile trawl surveys at Walter Slough, Pea Island Flats, and Rodanthe Flats, the most abundant species at all sites during the

May to June sample period were pinfish (*Lagodon rhomboides*), pigfish (*Orthopristis chrysoptera*), spot (*Leiostomus xanthurus*), silver perch (*Bairdiella chrysoura*), pipefish (*Syngnathus* spp.), and blue crabs (*Callinectes sapidus*). During July to September, the most frequently collected species were pink shrimp (*Penaeus duorarum*), grass shrimp (*Palaemonetes* spp.), pigfish, pipefish, and blue crabs (NCDENR-DMF, unpublished data, 1990-2003).

The sound supports many recreationally and commercially important fish and shellfish including: blue crab, Atlantic croaker (*Micropogonias undulatus*), spot, shrimp (*Penaeus aztecus*, *P. duorarum*, and *P. setiferus*), weakfish (*Cynoscion regalis*), and flounder (*Paralichthys lethostigma*, *P. dentatus*, and *P. albigutta*). In assessing commercial fisheries, an attempt was made to use only the fish and shellfish data collected for those locations and vessels most relevant to the project area. Therefore, the fish and shellfish catch statistics are limited to boats leaving from Dare County. Furthermore, commercial landings are broken down by these water bodies:

- The Roanoke Sound;
- The waters of the Pamlico Sound within Dare County; and
- The Atlantic Ocean less than 3 miles (4.8 kilometers) from shore.

Based on these data, blue crabs and flounder are by far the most valuable commercial species in the Roanoke and Pamlico sounds. Also of commercial significance are striped mullet (*Mugil cephalus*), commercial shrimp (*Penaeus sp.*), striped bass (*Morone saxatilis*), and sea trout (*Cynoscion sp.*). The weight and dollar value of finfish and shellfish harvests for each water body in 2002 are shown in Table 3-20. Harvests from 1990 to 2002 are presented in the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2005).

Table 3-20. 2002 Fish Harvests in the Project Area

Atlantic Ocean[1]		Pamlico Sound		Roanoke Sound	
Dollars	**Pounds**	**Dollars**	**Pounds**	**Dollars**	**Pounds**
Shellfish Harvest[2]					
$1,123,228	500,043	$2,009,757	1,923,248	$2,099,565	1,796,542
Finfish Harvest					
$12,052,456	17,664,154	$1,306,496	1,842,488	$183,052	206,791

Source: NCDENR-Division of Marine Fisheries. *Commercial Fish Landings by Boats Leaving from Dare County*, unpublished data, 2002.

[1] Atlantic Ocean refers to fish caught less than 3 miles (4.8 kilometers) from shore by boats leaving from Dare County, NC.

[2] Shellfish includes all non-finfish such as crabs, shrimp, clams, scallops, and oysters.

The areas of highest shellfish density (primarily clams and oysters) in the project area are Crab Slough, directly southwest of Oregon Inlet, and various locations along the shoreline of the Refuge. (Personal communication, July 28, 2003, Greg Allen, NCDENR-DMF.) There also are scattered shellfish beds west of Hatteras Island in 2 to 3 feet (0.6 to 0.9 meters) of water. Near the project area, shellfish beds also are found along the sound side of Bodie Island, just north of

Walter Slough. There are no leased shellfish areas within the project area. The closest leased bed is adjacent to Duck Island, more than 3 miles (4.8 kilometers) from southern Bodie Island. (Personal communication, June 18, 2003, Craig Hardy, NCDENR-DMF.)

Oyster restoration efforts in the Pamlico Sound have been underway for decades. Part of this effort involves yearly seeding with immature oysters by the DMF. Also included in cultch plantings were surf clams and scallops. During the period from 1985 to 1999, there were plantings in Walter Slough, Davis Slough, Old House Channel, and the area in between—all just west of Oregon Inlet. During the same period, several plantings also occurred within 2 miles (3.7 kilometers) west of Hatteras Island and Rodanthe. However, the only recent cultch plantings in the project area were at Walter Slough; 12,000 bushels of oysters were planted in 2000 and 2001. Another 18,000 bushels were planted in 2002 (NCDENR-DMF, unpublished data, 2003).

Several commercial fishing vessels and gear types are used in the Pamlico Sound. Among the most common gears are crab pots and crab trawls, flounder and shrimp trawls, gill nets, and pound nets (NCDENR-DMF, unpublished data, 2003). Most vessels operating in the waters of Dare County and the Atlantic Ocean are categorized as 19 to 50 feet (5.8 to 15.2 meters) in length. Most vessels longer than 50 feet (15.2 meters) are operating in the ocean, although some can be found in the Pamlico Sound as well. Table 3-21 presents commercial fishing vessel numbers and sizes for boats leaving from Dare County and operating in the Pamlico Sound or Atlantic Ocean.

Table 3-21. Dare County Commercial Fishing Vessels

Location (Where They Operate)	Vessel Length in Feet (Meters)	Year		
		2000	2001	2002
Waters of Dare County	1.0 – 18.0 (0.3 – 5.5)	266	246	226
	19.0 – 50.0 (5.8 – 15.2)	492	448	426
	> 50.0 (15.2)	19	17	20
Atlantic Ocean	1.0 – 18.0 (0.3 – 5.5)	62	66	100
	19.0 – 50.0 (5.8 – 15.2)	291	295	342
	> 50.0 (15.2)	71	96	88

3.7.6.3 Essential Fish Habitat

The Magnuson-Stevens Fishery Conservation and Management Act (16 USC 1801 et seq.) requires the US Secretary of Commerce to develop guidelines assisting regional fisheries management councils in identifying and creating management and conservation plans for EFH. Each council is required to amend existing fisheries management plans (FMPs) to include EFH designations and conservation requirements. The Act also requires federal agencies to consult with the Secretary on all actions, or proposed actions—authorized, funded, or undertaken by the agency—that might adversely affect EFH.

EFH is defined as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" (16 USC 1802(10)). "Waters" include aquatic areas and their associated physical, chemical, and biological properties that are used by fish and can include aquatic areas historically used by fish where appropriate. "Substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities. "Necessary" means the habitat is required to support a sustainable fishery and the managed species' contribution to a healthy ecosystem. "Spawning, breeding, feeding, or growth to maturity" covers a species' full life cycle. EFH designations are required only for species or species units for which councils have developed FMPs.

Managed species found in the project area fall under the joint responsibility of the South Atlantic Fisheries Management Council (SAFMC), the Mid-Atlantic Fisheries Management Council (MAFMC), and NMFS. The SAFMC has defined several habitats to be EFH for managed species (SAFMC, 1998). Habitat types and their presence in the project area (SAFMC, 1998) are shown in Table 3-22.

The paragraphs that follow present brief descriptions of EFH habitats in the project area. More detail is presented in the *Essential Fish Habitat Assessment* (CZR, Incorporated, 2008).

Table 3-22. Inshore and Marine Essential Fish Habitats

Inshore	Found in Project Area
Estuarine emergent	Yes
Estuarine shrub/scrub (mangrove)	No
Seagrass	Yes
Oyster reef and shell bank	Yes
Intertidal flats	Yes
Palustrine emergent and forested (freshwater)	Yes (interdunal swales)
Aquatic bed (tidal freshwater)	No
Estuarine water column	Yes
Marine	
Live/hard bottom	No
Coral and coral reef	No
Artificial/manmade reef	No
Sargassum	No
Water column	Yes

Source: South Atlantic Fisheries Management Council, 1998

Estuarine Emergent

Estuarine emergent wetlands are brackish and salt marsh habitats. The sound side wetlands that fringe Bodie Island, Hatteras Island, and Rodanthe are almost entirely wetlands of this type. Salt marshes are nutrient-rich and have high primary productivity, allowing these habitats to support a

diversity of fish, invertebrates, and waterfowl. Fish use salt marsh wetlands during multiple life stages because they provide nursery habitat for juveniles and foraging areas for adults. Descriptions of estuarine emergent habitats within the project area are presented in Section 3.7.3.

Palustrine Emergent

Palustrine emergent systems include tidal and non-tidal marshes. Because of the primary productivity of this habitat, this typically wet transition zone supports a variety of aquatic organisms. Like estuarine emergent wetlands, palustrine emergent wetlands serve an important function as nursery habitat for managed species. However, the palustrine emergent wetlands within the project area usually are interdune maritime grasslands, as described in Section 3.7.3.5, and do not have the ecological function typical of other palustrine emergent wetlands.

Seagrass

Seagrasses, mainly eelgrass and shoalgrass, are found in the high salinity areas of the Pamlico Sound generally in waters less than 6 feet (1.8 meters) deep. The Pamlico Sound has some of the most expansive seagrass (or SAV) beds in North Carolina. The distribution and composition of seagrass communities are influenced by several factors; among the most important factors are light, salinity, wave action, and nutrient levels. For many juvenile and adult fish, the structural complexity of seagrass habitat provides refuge from predators. These habitats are also rich in invertebrates and, therefore, serve as important foraging areas.

Oyster Reef and Shell Bank

Oyster reefs and shell banks are intertidal or subtidal habitats composed of living shellfish or artifact shell material. Several species of specialized fish and invertebrates are associated with oyster reefs as these habitats provide food and cover. Living oyster populations are limited by, among other things, siltation, salinity, and substrate. Throughout their entire Atlantic range, oyster reefs have declined substantially in the last century because of natural and anthropogenic stressors. Efforts currently are underway to regenerate oyster reefs. Bottom surveys conducted by the DMF suggest that shell bottom and large living oyster reefs are uncommon in the project area (NCDENR-DMF, unpublished data, 2003). The heaviest concentrations are in Crab Slough. (See Section 3.7.6.2 for a description of shellfish resources.)

Intertidal Flats

Intertidal flats are un-vegetated or sparsely vegetated, sandy or soft bottom areas and are found throughout the project area. The flats provide year round habitat for invertebrates and are important feeding areas for both resident fishes and seasonal migrants. Particularly important is the microhabitat known as the "marsh edge," or the detritus-rich area where the flats interface with marsh vegetation. The spatial extent of intertidal flats is determined by local topography and tidal amplitude.

Estuarine Water Column

The estuarine water column extends from the estuarine bottom to the surface waters. This habitat encompasses oligohaline (low salinity), mesohaline (moderate salinity), and polyhaline (high salinity) waters, which includes all open water of the Pamlico Sound. Distinct zones within the water column can be defined by several parameters such as temperature, salinity, and dissolved oxygen. Water column zonation is continually fluctuating and is a function of tidal dynamics, season, nutrient levels, and proximity to the ocean.

Fish and shellfish often exploit distinct resources within the water column based on species-specific diet, behavior, and morphology. For example, demersal fishes (bottom dwelling) are adapted for bottom habitat and typically exhibit specialized feeding organs, body shape, and

coloration, whereas estuarine pelagic fishes are those adapted for swimming and feeding higher in the water column.

Marine Water Column

The marine water column in the project area includes the waters of Oregon Inlet. Like the estuarine water column, marine waters have biological and chemical gradients that exhibit spatial and temporal variation. Non-estuarine-dependent fish and shellfish use this habitat during all stages of their life-cycle.

Oregon Inlet is a key corridor for larval fish to enter estuarine nursery areas. Several studies of larval fish flux exist for Oregon Inlet. Joyeux (1999) found five taxa to be most abundant: Atlantic menhaden (*Brevoortia tyrannus*), Atlantic croaker (*Micropogonius undulatus*), spot (*Leiostomus xanthurus*), pinfish (*Lagodon rhomboides*), and flatfishes of the genus *Paralichthys.* Hettler and Barker (1993) found 60 taxa, with anchovies (*Anchoa* sp.), clupeoids, and Atlantic croaker larvae to be the most abundant at Oregon Inlet. They also found that ichthyoplankton abundance was greatest in August and lowest in February. Larval fish use active (vertical migration) and passive processes (tidal transport; wind driven currents) for transport through Oregon Inlet.

The SAFMC and MAFMC have developed fisheries management plans for several species, or species units (SAFMC, 1998; MAFMC, 1998), although not all species are found in the project area. In addition, highly migratory species FMPs and Atlantic billfish FMPs were developed by the Highly Migratory Species Management Unit, Office of Sustainable Fisheries, National Marine Fisheries Service (NMFS, 1999a; NMFS, 1999b). As part of each FMP, the council designates not only EFH, but also Habitat Areas of Particular Concern (HAPC), a subset of EFH that refers to specific locations required by a life stage(s) of that managed species. Table 3-23 presents the species or species units for which FMPs exist, whether these species are found within the project area, and designated EFH and HAPC in the project area. Below is a description of managed species with EFH found in the project area.

Atlantic mackerel (Scomber scombrus)

Atlantic Mackerel are pelagic, primarily piscivorous species (fish that eat other fish) found along the Atlantic coast from Labrador to Cape Hatteras. Spawning occurs throughout its range along the continental shelf in waters less than 50 feet (15.2 meters) in depth. Inshore waters around Oregon Inlet, but not the Pamlico Sound, are considered EFH for all life stages. Atlantic mackerel generally are not found in the Pamlico Sound at any life stage, but do use the more northern estuaries. No HAPC has been designated by the MAFMC.

Black Sea Bass (Centropristis striata)

The black sea bass is a demersal species (bottom dwelling) found from Maine to Florida. Spawning occurs offshore from May to October along the continental shelf in an area extending from southern New England to North Carolina. Larvae develop in coastal waters and estuaries, with highest concentrations from Virginia to New York. As juveniles and adults, this species is associated with submerged structure in estuarine and marine waters. Black sea bass enter Pamlico Sound during the late spring, summer, and fall to take advantage of seasonally abundant fish and invertebrate prey. Inshore waters around Oregon Inlet are designated EFH by the MAFMC for larval, juvenile, and adult life stages. Black sea bass are considered part of the Snapper Grouper Complex by the SAFMC, and all estuarine emergent wetlands, SAV, oyster reef and shell banks, and unconsolidated bottom habitats within the project area are designated EFH by the SAFMC. In addition, oyster shell bank habitat within the Pamlico Sound is designated EFH-HAPC for black sea bass by the SAFMC. This species is considered over-fished by the MAFMC.

Table 3-23. Managed Fish Species or Species Units Listed by Manager

Species	Present in Project Area	Life stages for EFH Present in Project Area	Designated EFH in Project Area	HAPC in Project Area
Mid-Atlantic Fisheries Management Council (MAFMC)				
Atlantic mackerel (*Scomber scombrus*)	Yes	Eggs, larvae, juveniles, adults	Inshore coastal waters	None
Atlantic surfclam (*Spisula solidissima*)	No	None	None	None
Black sea bass (*Centropristis striata*)	Yes	Eggs, larvae, juveniles, adults	Inshore coastal waters; Pamlico Sound	SAV, oyster/ shellbank
Bluefish (*Pomatomus saltatrix*)	Yes	Eggs, larvae, juveniles, adults	Inshore coastal waters, Pamlico Sound	None
Butterfish (*Peprilus triacanthus*)	Yes	Eggs, larvae, juveniles, adults	Inshore coastal waters	None
Spiny dogfish (*Squalus acanthius*)	Yes	Juveniles, adults	Inshore coastal waters	None
Longfin squid (*Loligo pealei*)	Yes	Pre-recruit, recruit	Inshore coastal waters	None
Monkfish (*Lophius americanus*)	No	None	None	None
Ocean quahog (*Artica islandica*)	No	None	None	None
Summer flounder (*Paralichthys dentatus*)	Yes	Eggs, larvae, juveniles, adults	Inshore coastal waters, Pamlico Sound	SAV
Scup (*Stenotomus chrysops*)	Yes	Juveniles, adults	Inshore coastal waters; Pamlico Sound	SAV, oyster/ shellbank
Shortfin squid (*Illex Illecebrosus*)	Yes	Pre-recruit, recruit	Inshore coastal waters	None
Tilefish (*Lopholatilus chamaeleonticeps*)	No	None	None	None
South Atlantic Fisheries Management Council (SAFMC)				
Penaeid and rock shrimp (Penaeus sp. & Sicyonia sp.)	Yes	Eggs, larvae, juveniles, adults	Pamlico Sound, Inshore coastal waters	Oregon Inlet; Pamlico Sound
Red drum (*Sciaenops ocellatus*)	Yes	Eggs, larvae, juveniles, adults	Pamlico Sound, Inshore coastal waters	Oregon Inlet, SAV
Snapper Grouper management unit	Yes	Juveniles, adults	Pamlico Sound, Inshore coastal waters	Oregon Inlet, SAV, oyster/shell bank
Golden crab (*Chaeceon fenneri*)	No	None	None	None
Spiny lobster (*Panulirus argus*)	No	None	None	None
Coastal migratory pelagic species	Yes	Eggs, larvae, juveniles, adults	Pamlico Sound, Inshore coastal waters	None
Sargassum (*Sargassum* sp.)	No	None	None	None
Calico scallop (*Agopecten gibbus*)	No	None	None	None
Coral, coral reef, and live/hardbottom habitat	No	None	None	None
National Marine Fisheries Service (NMFS)				
Highly migratory species (sharks, tuna, swordfish)	Yes	Juveniles, adults	Pamlico Sound, Atlantic coast	Pamlico Sound adjacent to Hatteras Island
Billfish	No	None	None	None

Source: MAFMC, 1998; SAFMC 1998, NMFS, 1999a, 1999b.

Bluefish (Pomatomus saltatrix)

Bluefish are pelagic fish found in coastal waters from Nova Scotia to South America. Adults are piscivorous (eat other fish) and generally feed on small baitfish in inshore and estuarine habitats. This species makes long-distance migrations to Florida during the fall and migrate north during the spring. They are seasonal visitors to the Pamlico Sound, with the greatest abundance from April to October. Spawning takes place on the continental shelf at various times of the year depending on location. Inshore waters around Oregon Inlet are designated EFH for all life stages. The estuaries of the Pamlico Sound are designated EFH for juvenile and adult life stages by the MAFMC. No HAPC has been designated by the MAFMC. This species is considered over-fished by the MAFMC.

Butterfish (Peprilus triacanthus)

Butterfish are found in coastal waters from Newfoundland to Florida. Spawning occurs offshore, but larvae and juveniles make use of estuaries during growth. Adults are seasonal migrants that winter in offshore waters or warm coastal waters near the southern states. The MAFMC has designated pelagic waters greater than 33 feet (10.1 meters) in depth as EFH for all life stages. No HAPC has been designated by the MAFMC.

Spiny Dogfish (Squalus acanthius)

Spiny dogfish are cartilaginous fish (having a skeleton made of cartilage) found in shallow and deep waters of the continental shelf from Labrador to Cuba. This species is a livebearer that gives birth to litters of 1 to 15 pups during winter in inshore waters. The primary prey items for dogfish are fish and, to a lesser extent, squid and crustaceans. For juveniles and adults, the MAFMC has designated inshore waters around Oregon Inlet as spiny dogfish EFH. This species is considered over-fished by the MAFMC, but no HAPC has been designated by the MAFMC.

Summer flounder (Paralichys dentatus)

The summer flounder is an estuarine-dependent species found along the Atlantic coast from Maine to Florida. Spawning occurs from Cape Cod to Cape Hatteras between October and May along the continental shelf in waters 30 to 360 feet (9.1 to 109.8 meters) in depth. Larvae enter the estuaries, including the Pamlico Sound, in the late winter and spring where they develop into juveniles before migrating to the ocean during the fall. As adults, summer flounder continue to make seasonal use of estuaries. The MAFMC designates inshore waters around Oregon Inlet as EFH for all life stages and designates the estuaries of the Pamlico Sound as EFH for larval, juvenile, and adult life stages. In addition, the SAV beds of the Pamlico Sound are designated HAPC by the MAFMC. This species is considered over-fished by the MAFMC.

Scup (Stenotomus chrysops)

Scup are found from Nova Scotia to eastern Florida, but are rare south of North Carolina. Scup are migratory species that occupy offshore waters in winter and inshore waters from spring to fall. Their diet consists mainly of invertebrates such as crustaceans and mollusks. The MAFMC has not designated EFH for scup in the Pamlico Sound or Oregon Inlet; however, this species is considered over-fished by the MAFMC. Scup are considered part of the Snapper Grouper Complex by the SAFMC. Therefore, all estuarine emergent wetlands, SAV, oyster reef and shell banks, and unconsolidated bottom habitats within the project area are designated EFH by the SAFMC. In addition, the SAFMC designated SAV and oyster shell bank habitat within the Pamlico Sound as EFH-HAPC for scup.

Shortfin Squid (Ilex illecebrosus)

Shortfin squid are distributed from Labrador to Florida, with the greatest abundance between Cape Hatteras and Newfoundland. Shortfin squid make long-distance fall migrations to spawning areas south of Cape Hatteras, after which larvae and juveniles are transported by the Gulf Stream to more northern waters. Adults feed primarily on small fish, crustaceans, and other squid. The most important predators of shortfin squid are billfish, sharks, tunas, and marine mammals. EFH in the project area includes nearshore coastal waters around Oregon Inlet. No EFH is designated for the Pamlico Sound.

Longfin Squid (Loligo pealeii)

Longfin squid are distributed from Labrador to the Gulf of Venezuela, with the greatest abundance between Cape Hatteras and Georges Bank. Like shortfin squid, longfin squid make long-distance migrations along the coast and from inshore to offshore waters of the continental shelf. Typically, this species overwinters offshore and moves in to warm inshore waters during the spring and summer months. Spawning occurs year-round. Adults feed primarily on small fish, crustaceans, and other squid. The most important predators of shortfin squid are billfish, sharks, tunas, and marine mammals. EFH in the project area includes nearshore coastal waters around Oregon Inlet. No EFH is designated for the Pamlico Sound.

Penaeid and Rock Shrimp (Penaeus sp.)

Penaeid shrimp (white, pink, and brown shrimp) are estuarine dependent species of ecological and commercial importance. Penaeid shrimp spawn offshore where larval and postlarval development occurs as well. After currents carry postlarvae into estuaries, shrimp distribute themselves according to substrate and salinity preference. As shrimp grow, they migrate to deeper, high salinity waters before leaving for offshore spawning grounds. All estuarine emergent wetlands, SAV, oyster reef and shell banks, subtidal and intertidal flats, and ocean surf zone habitats within the project area are designated penaeid shrimp EFH. Also, portions of the project area are designated HAPCs for penaeid shrimp. There are no rock shrimp or rock shrimp EFH in the project area.

Red Drum (Sciaenops ocellatus)

Red drum are found in the coastal waters, inlets, and estuaries of the Atlantic coast from Massachusetts to northern Mexico. Spawning occurs in shallow water along beaches and inlets after which eggs and larvae are carried into estuaries where juvenile development takes place. Juvenile feed and grow during the warmer months before moving into deep estuarine or oceanic waters. As adults, red drum make pronounced seasonal migrations along the coast, moving offshore or to southern waters in fall and back to more northern, inshore waters in the spring. Red drum arrive at the Pamlico Sound between March and April, with a second peak in abundance during fall as fish begin migrating south from the Mid-Atlantic states. All estuarine emergent wetlands, SAV, oyster reef and shell banks, unconsolidated bottom, and ocean surf zone habitats within the project area are designated red drum EFH. Oregon Inlet and the SAV beds of the Pamlico Sound are designated HAPCs for red drum.

Snapper Grouper Management Unit

More than 70 species of fish, occupying a range of niches, are included in the snapper grouper management unit. Although most of these species occupy offshore structure and are not found within the project area, several representatives from the following families of fish are seasonally present: snapper (*Lutjanidae*), triggerfish (*Balistidae*), jacks (*Carangidae*), spadefish (*Ephippidae*), sea bass and grouper (*Serranidae*), and porgies (*Sparidae*). In addition, several estuarine dependent species like mutton snapper (*Lutjanus analis*), gray snapper (*L. griseus*), and lane snapper (*L. synagris*) can be found in the Pamlico Sound. For these estuarine dependent species, all estuarine emergent wetlands,

SAV, oyster reef and shell banks, and unconsolidated bottom habitats within the project area are designated EFH. Oregon Inlet, SAV, and oyster shell bank habitat within the project area are designated HAPC for the snapper grouper species complex.

Coastal Migratory Pelagics

This category refers to six species of migratory fish found along the Atlantic coast from nearshore to the edge of the continental shelf. While adults generally are found offshore, their prey is often estuarine dependent; therefore, estuarine habitats are considered part of the coastal migratory pelagic management unit. Coastal migratory pelagics occurring in the project area include cobia (*Rachycentron canadum*), Spanish mackerel (*Scomberomorus maculatus*) and king mackerel (*Scomberomorus cavalla*). Oregon inlet is designated as EFH for all these species; additionally, the high salinity portions of the Pamlico Sound are considered EFH for cobia. No HAPC for coastal migratory pelagics are designated in the project area.

Highly Migratory Species and Atlantic Billfish

Highly migratory species include swordfish (*Xiphias galdius*), five species of tuna, and 39 species of shark. The billfish FMP designates EFH for blue marlin (*Makaira nigricans*), white marlin (*Tetrapturus albidus*), sailfish (*Istiophorus platypterus*), and longbill spearfish (*Tetrapturus pfluegeri*). Highly migratory species display a wide diversity of geographic distributions and life-histories. Billfish, tuna, and swordfish generally are offshore pelagic species at all life stages and NMFS has not designated any EFH within the project area for these fish. Several managed sharks do make use of inshore coastal habitat and estuaries; for these species, designated EFH includes shallow inshore waters around Oregon Inlet. These sharks are: scalloped hammerhead (*Sphyrna lewini*), blacktip shark (*Carcharhinus limbatus*), dusky shark (*Carcharhinus obscurus*), sandbar shark (*Carcharhinus plumbeus*), spinner shark (*Charcharhinus brevipinna*), tiger shark (*Galeocerdo cuvieri*), sand tiger shark, (*Odontaspis taurus*), and Atlantic sharpnose (*Rhizoprionodon terraenovae*).

Some species also make use of estuarine habitat, including the dusky shark and Atlantic sharpnose. For these species, EFH includes high-salinity estuarine waters of the Pamlico Sound. Additionally, shallow areas near the Outer Banks and in areas of the Pamlico Sound adjacent to Hatteras and Ocracoke islands and offshore of those islands are important nursery and pupping grounds for the sandbar shark; therefore, these locations are designated HAPC for this species.

3.7.6.4 Benthic Communities

Bottom-dwelling polychaetes, oligochaetes, amphipods, isopods, and the commercially valuable oyster (*Crassostrea virginica*) and hard clam (*Mercenaria mercenaria*) ingest both phytoplankton and zooplankton. Benthos (organisms that live on or in the bottom sediments of a body of water) found near Oregon Inlet, as documented by the NCDENR, indicate that polychaetes (*Nereis succinea, Laeonereis culveri,* and *Heteromastus filiformis*), decapods (*Rithropanopeus harrisii* and *Palaemonetes pugio*), amphipods (*Corophium lacustre, Gammarus fasciatus* and *G. palustrus*), isopods (*Cyathura polita* and *Cassidinidea ovalis*), tanaids (*Hargeria repax*), and mollusks (*Rangia cuneata, Geukensia demissa, Macoma balthica* and *Teredo* sp.) are frequently found in the nearby sounds. (Personal communication, August 14, 1990, Lawrence Eaton, Division of Environmental Management.)

The DWQ conducts benthic sampling biannually throughout the state as part of the Benthic Macroinvertebrate Ambient Network (BMAN) monitoring program. Using these surveys, an index of biotic integrity (BI) can be formulated and used to assess water quality at the sample location. The most recent survey, conducted in 1995 near Hatteras Island, found 76 species of

macroinvertebrates and yielded a BI score of 2.8. The species richness and BI value for the Hatteras Island sample were higher than those found for estuaries along the Croatan Sound, Currituck Sound, Roanoke Sound, and the Alligator River (NCDENR, 2002).

3.7.6.5 Wildlife

Compared to the Dare County mainland, the project area contains fewer species of mammals, reptiles, and amphibians. Terrestrial species diversity likely is limited by commercial and residential development; however, natural factors (e.g., corridors, access, fragmented communities) are responsible as well. As a series of islands, geographic barriers exist that prevent the immigration of individuals from mainland populations. Also, most of the surface water resources are brackish to salt, limiting habitat use by reptiles and amphibians.

The greatest faunal abundance and species richness is typically found in the dune, marsh, and maritime shrub communities. Biotic community types and their associated fauna are described in Section 3.7.3.

Hunting is not permitted in the project area. Waterfowl hunting is permitted in certain locations, as described below in Section 3.7.6.6.

During surveys, wildlife identification involved a variety of observation techniques, including visual observations (both with and without the use of binoculars) and observing the characteristic signs of wildlife (sounds, scats, tracks, and burrows). Quantitative water sampling was not undertaken to support existing data. Evidence or individuals of a wide variety of animal species were observed within the project area. Species observed and evidence of species observed are indicated with an asterisk (*).

The project area likely exhibits a limited diversity of amphibian species. Environments such as freshwater ponds, bogs, and damp forests are very scarce on the island, and few amphibians survive in the salty ecosystem. Typical amphibians likely to be found in the project area include the two-toed amphiuma (*Amphiuma means*), green treefrog (*Hyla cinerea*), squirrel treefrog (*Hyla squirella*), leopard frog (*Rana utricularia*), and bullfrog (*Rana catesbiana*).

The variety of reptiles on the islands is greater than that of amphibians. Reptiles in the project area likely include rat snake* (*Elaphe obsolete*), black racer snake* (*Coluber constrictor*), rough green snake (*Opheodrys aestiva*), brown water snake* (*Nerodia taxispilota*), yellowbelly slider turtle* (*Chrysemys scripta*), mud turtle (*Kinosternon subrubrum*), snapping turtle* (*Chelydra serpentina*), Carolina diamondback terrapin (*Malaclemys terrapin centrata*), southeastern five-lined skink (*Eumeces inexpectatus*), and six-lined racerunner (*Cnemidophorus sexlineatus*).

Many birds utilize marsh environments for breeding sites and foraging. Red-winged blackbird* (*Agelaius phoeniceus*) was the most commonly observed bird in both the black needlerush and salt shrub communities. Other birds observed in the marshes were northern mockingbird* (*Mimus polyglottus*), merlin* (*Falco columbarius*), killdeer* (*Charadrius vociferous*), great horned owl* (*Bubo virginianus*), snowy egret* (*Egretta thula*), boat-tailed grackle* (*Quiscalus major*), and common grackle* (*Q. quiscula*). Waterfowl and other birds observed in open water habitats in the project area included tundra swan* (*Cygnuss columbianus*), snow goose* (*Chen caerulescens*), American black duck* (*Anas rubrides*), Canada goose* (*Branta canadensis*), double-crested cormorant* (*Phalacrocorax auritus*), hooded merganser* (*Ophodytes cucullatus*), belted kingfisher* (*Ceryle alcyon*), dunlin* (*Calidris alpine*), blue-winged teal* (*Anas discors*), and great blue heron* (*Ardea herodias*). Additional birds observed include the house finch*

(*Carpodacus mexicanus*), white ibis* (*Eudocimus albus*), and American white pelican* (P*elecanus erythrorhynchos*). Many birds were observed fishing over Pamlico Sound. They included several species of gulls* (*Larus* spp.), brown pelican* (*Pelecanus occidentalis*), and northern harrier* (*Circus cyaneus*). Other bird species expected to be found in these communities, but not observed, include marsh wren (*Cistothorus palustris*), salt marsh sharp-tailed sparrow (*Ammodramus caudacutus*), prothonotary warbler (*Protonotaria citrea*), and osprey (*Pandion haliaetus*).

The diversity of mammals on the Outer Banks is limited because of the over-water distance from the mainland. Evidence of marsh rabbits* (*Sylvilagus palustris*) and/or eastern cottontails* (*Sylvilagus floridanus*) were readily observed throughout the project area. White-tailed deer* (*Odocoileus virginianus*) and raccoon* (*Procyon lotor*) were observed throughout the project area. Evidence of red fox* (*Vulpes vulpes*) and river otter* (*Lutra canadensis*) was also observed throughout the area. Nutria* (*Myocastor coypus*), an introduced South American rodent, is a common inhabitant of the marshes along the Outer Banks. Other mammals likely to be in the project area include muskrat (*Ondatra zibethicus*), marsh rice rat (*Oryzomys palustris*), cotton mouse (*Peromyscus gossypinus*), and mink (*Mustela vison*). In addition, present all along the Outer Banks are feral cats* (*Felis sylvestris*), which have likely increased predation on native fauna.

3.7.6.6 Migratory Birds

Birds represent a highly visible and important resource of the Outer Banks. Because of the diversity and abundance of bird life on Hatteras Island, it is often referred to as "birder's paradise". Along the Atlantic Flyway, the Refuge has a bird list of 365 species that occur with regularity, and another 50 species that are considered accidental visitors. Although wintering waterfowl may find suitable refuge sites along much of the Outer Banks, the presence of an abundant food source attracts most species to the Refuge. Shifting shoals, coastal marshes, and submersed beds of aquatic vegetation offer a variety of substrates for feeding waterfowl.

The National Audubon Society has designated Important Bird Areas based on criteria that includes the presence of protected or vulnerable species and bird habitats, the importance of the site to bird research, and locations that hold significant concentrations of one or more species during the year (e.g., greater than 1,000 waterfowl or shorebirds). Using these criteria, the National Audubon Society has designated the entire Seashore and Refuge as Important Bird Areas. Also, because of their importance to protected species and habitat use by terns, all Oregon Inlet shoals are designated Important Bird Areas by the National Audubon Society.

The diverse habitats surrounding Bonner Bridge are used throughout the year by many avian species. To document habitat use by birds, the North Carolina Wildlife Resources Commission (NCWRC), the USFWS, and the NPS coordinate periodic bird population and nesting surveys at the southern and northern sides of Oregon Inlet. Data from nesting surveys at the north end of the Refuge illustrate the importance of this area to breeding shorebirds such as black skimmers (*Rynchops niger*), common terns (*Sterna hirunda*), gull-billed terns (*Sterna nilotica*), and least terns (*Sterna antillarum*). Based on 2002 survey data, sanderling (*Calidris alba*), willet (*Catoptrophorus semipalmatus*), semipalmated plovers (*Charadrius semipalmatus*) and semipalmated sandpipers (*Calidris pusilla*) were the most common shorebirds at south Bodie Island near Oregon Inlet (NPS, unpublished data, 2003). The sand and mudflats at the south end of Bodie Island also attract many shorebirds, including federally protected piping plover (*Charadrius melodus*). Pearson et al. (1959) indicates the species was a casual summer resident at Hatteras Island (then Pea Island), with nests found in 1901 and 1902. During the last ten years, piping plover breeding pairs were observed during several years at the south end of Bodie Island

(NCWRC, unpublished data, 2003). Over the same period, piping plover breeding pairs also were recorded at the north end of the Refuge near Oregon Inlet (NCWRC, unpublished data, 2003). See Section 3.7.7 for a complete description of habitat use by piping plover. The federally-listed threatened roseate terns (*S. dougallii*) occasionally forage and rest on the mudflats and adjacent inshore ocean. In addition, two protected species, the southeastern bald eagle (*Haliaeetus leucocephalus)* and peregrine falcon (*Falco peregrinus*), are found regularly during migration and occasionally as winter residents in the area (USFWS, 1988a).

The Refuge encompasses, or has some jurisdiction over, 25,700 acres (10,405 hectares) of Pamlico Sound waters and a series of manmade ponds/impoundments that also provide substantial habitat for waterfowl. Water levels in the impoundments are seasonally manipulated in such a way as to maximize food production and produce optimal feeding conditions for waterfowl and shorebirds. The Refuge is an important wintering ground for tundra swan (*Cygnus columbianus*), Canada geese, snow geese (*Chen caerulescens*), and more than 25 species of ducks (USFWS, 1988a). Winter waterfowl surveys conducted by the USFWS from 1999 to 2003 revealed that the most abundant waterfowl on the Refuge are black ducks (*Anas rubripes*), northern pintails (*Anas acuta*), American widgeons (*Anas americana*), gadwalls (*Anas strepeva*), green winged teals (*Anas crecca*), and snow geese. Surveys of the Pamlico Sound also are conducted by the USFWS. However, surveys are limited to within 1 mile (1.6 kilometers) west of Hatteras Island and do not extend out to the Pamlico Sound Bridge Corridor. The most abundant species in the sound are black ducks, buffleheads (*Bucephala albeola*), and pintails, with American widgeons, gadwalls, and snow geese also being common (USFWS, unpublished data, 2003). Survey results for 1999 to 2003 are presented in the *Natural Resources Technical Memorandum* (CZR, Incorporated, 2005).

In the past, high numbers of birds have wintered or nested in the Pamlico Sound on dredge spoil islands adjacent to Bonner Bridge. For example, several dredge spoil islands just west and northwest of Oregon Inlet (see Figure 3-7) traditionally support large colonies of nesting waterbirds. Royal terns (*Sterna maxima*) and brown pelicans (*Pelecanus occidentalis*) comprise the majority of nesting birds (Parnell and Soots, 1979; USFWS, 1988a). Common tern, least tern, sandwich tern (*S. sandvicensis*), gull-billed tern, Caspian tern (*Sterna caspia*), and black skimmer have nested on these islands as well (Parnell and Soots, 1979; Parnell and McCrimmon, 1984; Parnell and Shields, 1990). Similarly, Oregon Inlet Shoal (see Figure 3-7) also has large nesting populations of skimmers and terns. During a June 2003 survey, 73 black skimmer nests, three gull-billed tern nests, and 129 common tern nests were found on Oregon Inlet Shoal. (Personal communication, June 13, 2003, Marcia Lyons, NPS.) Although some dredge spoil islands, such as Island C (a nesting site for herons, egrets, and ibis), continue to provide nesting habitat, some of the spoil islands historically used by colonial waterbirds no longer serve as viable nesting areas. One dredge spoil island historically in the project area, Sand Shoal Island, washed out in the early 1990s; it no longer supports colonial waterbirds. Another island supported nesting waterbirds until 1999, but is now substantially eroded and nesting no longer occurs. However, both islands still serve as intertidal foraging areas. (Personal communication, September 3, 2003, Sue Cameron, NCWRC.)

Waterfowl hunting is permitted on Bodie Island but not in the waters of the Pamlico Sound from the Refuge to the community of Salvo. On Bodie Island, hunting is restricted by a lottery system that allows hunting from 20 permanent duck blinds, all of which are north of the project area. No temporary blinds are allowed on Bodie Island. Where permitted, hunting is regulated by the NPS in cooperation with the USFWS and the State of North Carolina.

3.7.7 Protected Species

Federally-listed floral and faunal species have been granted protection under the Endangered Species Act of 1973 (16 USC 1531-1543), which mandates federal agencies to ensure that any actions authorized, funded, or carried out by that agency do not jeopardize the "continued existence" of listed species, or result in the destruction or adverse modification of critical habitat (16 USC 1536). Proposed species are offered "limited protection" under Section 7(A)(C) of the Endangered Species Act of 1973, as amended.

Plants and animals with state designations of endangered, threatened, or special concern are granted protection by the State Endangered Species Act (GS 113-331 to 113-337) and the State of North Carolina Plant Protection and Conservation Act of 1979 (GS 196 106-202.19). These acts are administered and enforced by the North Carolina Wildlife Resources Commission (NCWRC) and the NC Department of Agriculture, respectively.

Federally-listed endangered, threatened, and proposed species that occur in the project area were identified from 15A North Carolina Administrative Code 101 and USFWS listings (Title 50 *Code of Federal Regulations* Sections 17.11 and 17.12, January 16, 2008) for Dare County. State-listed species were obtained from the North Carolina Natural Heritage Program (NCNHP) official list of protected species found in Dare County (NCNHP, July 2, 2007). The most current NCNHP database, NPS publications, and personal communication with NPS and NCWRC biologists were used to document species occurrence specifically within the Oregon Inlet area. The NCNHP database was also used to document species occurrence within the Refuge and northern Rodanthe during development of the Parallel Bridge Corridor. Plant and animal species that occur in Dare County and that are state- or federally-listed endangered or threatened, as well as federal species of concern, are listed in Table 3-24.

3.7.7.1 Federally-Listed Threatened and Endangered Species

The USFWS lists 13 federally-listed threatened or endangered species for Dare County as of January 16, 2008. The eight federally-listed endangered species are:

1. Red-cockaded woodpecker (*Picoides borealis*);
2. Hawksbill sea turtle (*Eretmochelys imbricata*);
3. Kemp's ridley sea turtle (*Lepidochelys kempii*);
4. Leatherback sea turtle (*Dermochelys coriacea*);
5. West Indian manatee (*Trichechus manatus*);
6. Shortnose sturgeon (*Acipenser brevirostrum*); and
7. Roseate tern (*Sterna dougallii*);
8. Red wolf (*Canis rufus*)—experimental.

Table 3-24. State and Federal Protected Species Listed for Dare County

Species	Current Status[1]		Habitat Type	Potential to Occur in the Project Area
	USFWS	NCNHP		
Mammals				
"Buxton Woods" white-footed mouse (*Peromyscus leucopus* ssp. 1)	FSC	SR	Maritime forests in Cape Hatteras vicinity	No
West Indian manatee (*Trichechus manatus)*	E	E	Coastal waters; warm waters of estuaries and river mouths	Yes
Red wolf (*Canis rufus*)	E-EXP	SR	Swamps, pocosins, extensive forests	No
Rafinesque's big-eared bat (*Corynorhinus rafinesquii*)	FSC[2]	T	Caves, mines, buildings; near water	No
Birds				
Bald eagle (*Haliaeetus leucocephalus*)	Not listed	T	Mature forests near large bodies of water (for nesting): lakes and sounds	Yes
Black rail (*Laterallus jamaicensis*)	FSC	SR	Brackish marsh	Yes
Gull-billed tern (*Gelochelidon nilotica*)	Not listed	T	Summer resident; ocean, sound, tidal flats, dunes	Yes
Peregrine falcon (*Falco peregrinus*)	Not listed	E	Transient and winter resident; ponds, marshes, tidal flats, and beaches	Yes
Piping plover (*Charadrius melodus*)	T	T	Resident; tidal flats, beach pools, and open beaches; northern and southern tips of Oregon Inlet are proposed piping plover critical habitat by the USFWS	Yes
Red-cockaded woodpecker (*Picoides borealis*)	E	E	Resident; mature open pine woodlands	No
Roseate tern (*Sterna dougallii*)	E	E	Transient; sound, open beaches, maritime islands	Yes
Reptiles				
American alligator (*Alligator mississippiensis*)	T[3]	T	Ponds, fresh to slightly brackish rivers and marshes	No
Green sea turtle (*Chelonia mydas*)	T	T	Ocean, sounds, nests on beaches	Yes
Hawksbill sea turtle (*Eretmochelys imbricata*)	E	E	Ocean, nests on beaches	Yes[5]
Kemp's ridley sea turtle (*Lepidochelys kempii*)	E	E	Ocean, sounds, nests on beaches	Yes[5]
Leatherback sea turtle (*Dermochelys coriacea*)	E	E	Ocean, nests on beaches	Yes[5]
Loggerhead sea turtle (*Caretta caretta*)	T	T	Ocean, sounds, nests on beaches	Yes
Northern diamondback terrapin (*Malaclemys terrapin terrapin*)[4]	FSC	SC	Sound-side marshes	Yes

Table 3-24 (concluded). State and Federal Protected Species Listed for Dare County

Species	Current Status[1]		Habitat Type	Potential to Occur in the Project Area
	USFWS	NCNHP		
Fish				
Shortnose sturgeon (*Acipenser brevirostrum*)	E	E	Brackish and freshwater rivers and estuaries	Yes[5]
Vascular Plants				
Blue witch grass (*Dichanthelium caerulescens*)	Not listed	E	Wet savannas with a calcareous influence	Yes
Carolina grasswort (*Lilaeopsis carolinensis*)	Not listed	T	Freshwater marshes and pond edges	Yes
"Dune bluecurls" (*Trichostema* sp. 1)	FSC	SR-L	Maritime grasslands behind foredunes; openings in maritime scrub	Yes
Saltmarsh spikerush (*Eleocharis halophila*)	Not listed	T	Salt and brackish marshes	Yes
Seabeach amaranth (*Amaranthus pumilus*)	T	T	Sand flats and low dunes	Yes[6]
Small-flowered hemicarpa (*Lipocarpha micrantha*)	Not listed	E	Drawdown zones of blackwater rivers, salt marshes	Yes
Snowy orchid (*Platanthera nivea*)	Not listed	T	Wet savannas	No
Invertebrates				
Hessel's hairstreak (*Callophrys hesseli*)	FSC	SR	Atlantic white cedar swamps	No

NOTES:

- Endangered – a taxon "in danger of extinction throughout all or a significant portion of its range."
- Threatened – a taxon "likely to become endangered within the foreseeable future throughout all or a significant portion of its range."
- FSC – A federal species of concern – a species that may or may not be listed in the future (formerly C2 candidate species or species under consideration for listing for which there is insufficient information to support listing).
- EXP – a taxon that is listed as experimental (either essential or nonessential). Experimental, nonessential endangered species (e.g., red wolf) are treated as threatened on public land, for consultation purposes, and as species proposed for listing on private land.
- The USFWS has jurisdiction over protected sea turtles when they are on land. When they are in the water, the NMFS has jurisdiction.

[1] Species as listed by the USFWS in January 2008 and the NCNHP in July 2007. E: Endangered; T: Threatened; FSC: federal species of concern; EXP: Experimental; SR: Significantly rare; SR-L: Significantly rare-limited; SR-T: Significantly rare-throughout range; SC: Special concern.

[2] Obscure record – date and location of observation uncertain.

[3] Listed because of similarity of appearance to American crocodile.

[4] The northern diamondback terrapin is a federal species of concern known to occur along the Outer Banks, but not on the USFWS protected species list for Dare County.

[5] Record from Pamlico Sound, Dare County in 2006 (personal communication, November 30, 2006, David Rabon, USFWS).

[6] The NCNHP has no records of the species within the project area, however, the NPS located a single seabeach amaranth on the Bodie Island flats (Latitude: 35° 46.790', Longitude: 75° 32.162') on July 6, 2004. (Personal communication, November 19, 2004, Marcia Lyons, Cape Hatteras National Seashore.)

The five federally-listed threatened species are:

1. Piping plover (*Charadrius melodus*);

2. Green sea turtle (*Chelonia mydas*);

3. Loggerhead sea turtle (*Caretta caretta*);

4. Seabeach amaranth (*Amaranthus pumilus*); and

5. American alligator (*Alligator mississippiensis*)—listed because of similarity of appearance to American crocodile (*Crocodylus acutus*).

According to the USFWS Red Wolf Recovery Team, the North Carolina red wolf experimental population only occurs on the mainland and therefore it is not discussed in this section. (Personal communication, December 1, 2006, Art Buyer, USFWS.)

Species descriptions, biological conclusions, potential for adverse impact, and the results of informal and formal consultation with USFWS and NMFS are presented in Section 4.7.7.

In addition to the federally-listed species listed above, bald eagles (*Haliaeetus leucocephalus*) were federally-listed. This species is now delisted; therefore, it is discussed under state-listed species in Section 3.7.7.4.

3.7.7.2 Federal Species of Concern

Seven species are identified by the USFWS as "species of concern" for Dare County. Table 3-25 lists the federal species of concern, their state status, and the existence of habitat within the project area. These species are not protected by federal law but may be elevated to protected status in the near future.

3.7.7.3 Federal Candidate Species

Seven species are identified by the USFWS as "candidate" species occurring in North Carolina. These species are not protected by federal law, but may be elevated to listed status in the near future:

1. Red knot (*Calidris canutus rufa*);

2. Sicklefin redhorse (*Moxostoma sp.*);

3. Bog asphodel (*Narthecium americanum*);

4. Georgia aster (*Symphyotrichum georgianum*);

5. Yadkin River goldenrod (*Solidago plumose*);

6. White fringeless orchid (*Platanthera integrilabia*); and

7. Hirsts' panic grass (*Dicanthelium hirstii*).

Table 3-25. Federal Species of Concern Known from Dare County, North Carolina

Common Name	Scientific Name	Federal Status	State Status	Habitat Requirements and Known Occurrences	Habitat Available in the Pamlico Sound Bridge Corridor?	Habitat Available in the Parallel Bridge Corridor?
Vertebrates						
American eel	*Anguilla rostrata*	FSC	NA[1]	Open oceans, large coastal tributaries, small freshwater streams, lakes and ponds.	Yes	Yes
Black rail	*Laterallus jamaicensis*	FSC	SR	Salt and brackish marshes amid juncus and cordgrasses, freshwater marshes, meadows, and grain fields. As of July 2003, the NCNHP database has a May 2000 record of a black rail[2].	Yes	Yes
Black-throated green warbler	*Dendroica virens waynei*	FSC	SR	Slow-moving headwaters of blackwater creeks and the swamps and swamp borders that feed blackwater rivers and their tributaries.	No	No
"Buxton Woods" white-footed mouse	*Peromyscus leucopus*	FSC	SR	Hardwood forests, field margins, myrtle thickets, marshes, canebrakes, and brushy fencerows.	No	No

Table 3-25 (concluded). Federal Species of Concern Known from Dare County, North Carolina

Common Name	Scientific Name	Federal Status	State Status	Habitat Requirements and Known Occurrences	Habitat Available in the Pamlico Sound Bridge Corridor?	Habitat Available in the Parallel Bridge Corridor?
Northern diamondback terrapin	*Malaclemys terrapin terrapin*	FSC	SC	Salt marshes and adjoining rivers, creeks, coves, and bays.	Yes	Yes
Rafinesque's big-eared bat	*Corynorhinus rafinesquii*	FSC	T	Dilapidated houses and buildings near permanent water, hollow trees, behind loose bark or at cave entrances.	No	No
Insects						
Hessel's hairstreak	*Callophrys hesseli*	FSC	SR	Atlantic white cedar swamps	No	No
Vascular Plants						
"Dune bluecurls"	*Trichostema* sp.1	FSC	SR-L	Between stable dunes, roadsides, thin woods and pinelands, and fields. The most northern occurrence of "Dune bluecurls" is near Buxton in southern Dare County[2].	Yes	Yes

NOTES:

- T – Threatened: A taxon likely to become endangered within the foreseeable future throughout all or a significant portion of its range.
- FSC – Federal species of concern: A species that may or may not be listed in the future.
- SR – Significantly rare: A species that exists in the state in low numbers and requires monitoring, but exists in greater numbers elsewhere within its range.
- SC – Special Concern: A species that is native or once native to North Carolina that is determined by the WRC to require monitoring.
- L – Range of species is limited to North Carolina and adjacent states, with 20 – 50 populations within the state and fewer than 50 total throughout its range.
- T – Species are rare throughout their ranges (fewer than 100 populations).

[1] NCNHP, 2007.
[2] Personal communication, October 17, 1991, Alan Weakley, NCNHP.

Red knots are the only vertebrate candidate species that are likely to occur in the project area. This species uses ephemeral habitats similar to those frequented by other shorebirds, and is often found in coastal North Carolina during migrations. The only other candidate species that may occur in Dare County is Hirsts' panic grass; however, this species prefers habitats that are not present in the project area (pond-cypress savannahs and limesinks; UNC, 2008).

3.7.7.4 North Carolina-Listed Species

The State Endangered Species Act (GS 113-331 to 113-337) provides for the conservation, management, enhancement, and protection of rare fauna in North Carolina. This law makes it unlawful to possess or disturb, for any reason not approved by the NCWRC, any animal on the protected list.

State-listed plant species are protected under the State of North Carolina Plant Protection and Conservation Act of 1979 (GS 196 106-202.12 to 106-202.19). It is illegal to: 1) dig, otherwise disturb, or remove any protected species without written permission of the landowner; or 2) sell, barter, or trade for any purpose any plant on the protected list, unless approved and permitted by the North Carolina Department of Agriculture.

State-listed plant species that occur in Dare County (in addition to those described above under federal species) are:

- Blue witch grass (*Dichanthelium caerulescens*);
- Saltmarsh spikerush (*Eleocharis halophila*);
- Carolina grasswort (*Lilaeopsis carolinensis*);
- Small-flowered hemicarpha (*Lipocarpha micrantha*); and
- Snowy orchid (*Platanthera nivea*).

The state-listed plant species listed above were designated as threatened by the state, except for blue witch grass and small-flowered hemicarpha. Blue witch grass occurs in wet savannas with a calcareous influence. The last known element occurrence was in the Refuge in 2003 (NCNHP, 2008). The saltmarsh spikerush prefers brackish and freshwater marshes; therefore, potential habitat is available within the project area. The only saltmarsh spikerush record from Dare County is from the Bodie Island Lighthouse Pond in 1984 and it was not observed during field verification of biotic communities for this document. The Carolina grasswort has only been documented from Dare County in the vicinity of Buxton, Currituck Sound, and the Cape Hatteras Lighthouse Pond. It prefers freshwater marshes, pools, and tidal marshes, all of which occur within the project area. The small-flowered hemicarpha, which occurs in drawdown zones of blackwater rivers and salt marshes, was last recorded on Hatteras Island in 1953 (personal communication, December 4, 2006, Harry LeGrand, NCNHP). The snowy orchid occurs in wet savannas, which do not occur within the project area.

State-listed animal species that occur in Dare County (in addition to those described above under federal species) are:

- Star-nosed mole – Coastal Plain Population (*Condylura cristata* pop. 1);
- Timber rattlesnake (*Crotalus horridus*);

- Little blue heron (*Egretta caerulea*);
- Snowy egret (*Egretta thula*);
- Tricolored heron (*Egretta tricolor*);
- Peregrine falcon;
- Gull-billed tern;
- Bald eagle;
- Outer Banks kingsnake (*Lampropeltis getula sticticeps*);
- Carolina water snake (*Nerodia sipedon williamengelsi*);
- Glossy ibis (*Plegadis facinellus*);
- Black skimmer (*Rynchops niger*);
- Common tern (*Sterna hirundo*); and
- Least tern (*Sternula antillarum*).

The state-listed animal species listed above were designated as Special Concern by the state. This designation is determined by the NCWRC to require monitoring; however, three bird species—the peregrine falcon (endangered), bald eagle (threatened), and the gull-billed tern (threatened)—are state-listed as endangered or threatened. Peregrine falcons are fairly common fall migrants and uncommon winter residents over all communities in the project area. Bald eagles were a federally-listed (threatened) species; however, they were delisted in June of 2007. Eagles continue to be federally-protected by the Migratory Bird Treaty Act of 1918, and receive unique federal protection from the Bald and Golden Eagle Protection Act of 1940. However, this species no longer requires formal consultation under the Endangered Species Act. Bald eagles occur in Dare County, but typically only use mature forests (not present in the project area) for nesting. The gull-billed tern regularly occurs within the project area and can be expected to use most non-woody communities (NCNHP database, 2006).

There are no known records of the star-nosed mole, timber rattlesnake, and Outer Banks kingsnake within the project area. Potential habitat does occur for the Outer Banks kingsnake (dunes, dry habitat), however, the closest known record is from Cape Hatteras Village. The Carolina water snake has been known to occur in the northern portion of Pea Island, with the last record being from 1992 (personal communication, December 4, 2006, Harry LeGrand, NCNHP). All colonial wading birds listed are known to occur and nest within the project area (personal communication, December 4, 2006, Sue Cameron, NCWRC).

3.8 Mineral Resources

There are no known mineral resources of economic value within either of the replacement bridge corridor alternatives.

3.9 Air Quality

In accordance with the Clean Air Act of 1970 (42 USC 7609, as amended in 1990 and 1997) the US Environmental Protection Agency (USEPA) established National Ambient Air Quality Standards (NAAQS) for the protection of public health and welfare. The NAAQS address the following six major pollutants: Carbon Monoxide (CO), Ozone (O_3), Nitrogen Dioxide (NO_2), Sulfur Dioxide (SO_2), Particulate Matter (PM_{10} and $PM_{2.5}$) and Lead (Pb). Of these six pollutants, the FHWA requires a detailed evaluation of CO.

3.9.1 Carbon Monoxide

The primary pollutant emitted from automobiles is carbon monoxide (CO). Automobiles are considered the major source of CO in the project area. The state and federal ambient air quality standards for carbon monoxide are:

- 1-hour - 35 ppm or 40 milligrams per cubic meter (mg/m^3); not to be exceeded more than once per year; and
- 8-hour - 9 ppm or 10 mg/m^3; not to be exceeded more than once per year.

Any 1-hour concentration above 35 ppm or 8-hour concentration above 9 ppm is considered a violation of the standards.

In order to determine potential CO concentrations at receptors near a highway, two concentration components must be used: local and background. The local component takes into account CO emitted by cars operating on highways near receptors (i.e., within 300 feet [91.4 meters]). The background component takes into account CO emitted by cars operating on streets farther from receptor locations. The background CO concentration for the project area is estimated to be 1.8 ppm. Consultation with the Air Quality Section of NCDENR's Division of Environmental Management indicated that an ambient CO concentration of 1.8 ppm is applied to most rural areas.

3.9.2 Other Emissions

Automobiles also are sources of hydrocarbons and nitrogen oxides. Hydrocarbons and nitrogen oxides emitted from cars in an urban area are mixed together in the atmosphere where they react with sunlight to form ozone, nitrogen dioxide, and other photochemical oxidants. It is the photochemical oxidants that are of concern and not the precursor hydrocarbons and nitrogen oxides.

The photochemical reactions that form ozone and nitrogen dioxide require several hours to occur. For this reason, the peak levels of ozone generally occur 6 to 12 miles (10 to 20 kilometers) downwind of the source of pollutant emissions. Urban areas generally are regarded as sources of photochemical oxidants, not individual streets and highways. The best example of this type of air pollution is the smog that forms in Los Angeles, California.

Area-wide automotive emissions of hydrocarbons and nitrogen oxides are expected to decrease in the future because of the continued installation and maintenance of pollution control devices on new cars. No appreciable changes in these emissions are expected on the proposed project.

Automobiles are not significant sources of particulate matter and sulfur dioxide. Nationwide, highway sources account for less than 7 percent of particulate matter emissions and less than 2 percent of sulfur dioxide emissions. Particulate matter and sulfur dioxide emissions are predominantly the result of non-highway sources (e.g., industrial, commercial, and agricultural activities). Because emissions of particulate matter and sulfur dioxide from cars are very low, there is no reason to suspect that traffic on the proposed project would cause air quality standards for particulate matter and sulfur dioxide to be exceeded.

Automobiles emit lead as a result of burning gasoline containing tetraethyl lead, which is added by refineries to increase the octane rating of the fuel. New cars with catalytic converters burn unleaded gasoline and emit no lead. Also, the USEPA has required a reduction in the lead content of leaded gasoline. The overall average lead content of gasoline in 1974 was 2 grams per gallon (0.53 grams per liter). By 1989, this composite average had dropped to 0.01 grams per gallon (0.003 grams per liter).

In the future, lead emissions are expected to decrease as more cars use unleaded fuels and as the lead content of leaded gasoline is reduced. Because of these reasons, exceeding NAAQS for lead is not a concern on highway improvement projects.

3.9.3 Regional Air Quality Standard Compliance

The project is in Dare County, which has been determined to be in compliance with the National Ambient Air Quality Standards. 40 CFR Parts 51 and 93 (Title 40, Parts 51 and 93 of the *Code of Federal Regulations*) are not applicable because the proposed project is in an attainment area. This project is not anticipated to create any adverse effects on the air quality of this attainment area.

3.10 Noise

3.10.1 Fundamental Concepts of Roadway Noise

Sounds exist in the human and natural environment at all times. Some sounds are necessary or desirable for communication or pleasure, some are unnoticed, and some are unwanted or disturbing. By definition, unwanted sounds are called *noise*. The following sections provide background for some of the concepts and terminology of sound and noise.

3.10.1.1 Generation of Sound

Sound is a disturbance that propagates as a wave through air, causing air particles to vibrate. Although the generating motion and the resultant motion of the air particles are very small, a sound wave can propagate over several miles (kilometers).

Three basic parameters of environmental noise play major roles in determining human subjective response. These parameters are:

- Intensity or level;
- Frequency spectrum; and
- Time-varying character.

3.10.1.2 Intensity

The first parameter of environmental noise—intensity or level—is quantified in decibels (dB). The range of pressure variations that the human ear can detect is tremendous; however, to describe sound in terms of pressure variations would be very cumbersome because of the great range of amplitudes that is involved. Therefore, a compressed scale was devised based upon the logarithm of the mean square pressure. The decibel or dB is the unit of this compressed scale. By using these units, the range of normally encountered sounds can be expressed as 20 to 140 dB rather than as 1 to 1,000,000.

3.10.1.3 Frequency

The second parameter of environmental noise that can be quantified is frequency. As a sound wave passes a point, the air pressure alternately rises and falls. Each time the pressure rises and falls, it completes one cycle. The number of cycles per second (called Hertz, Hz) is the unit in which frequency is expressed.

Frequency is observed subjectively as the tone or pitch of a sound. The human ear can detect a wide range of frequencies: from about 20 to 17,000 Hz. The low frequencies (20 – 500 Hz) have a low-pitched, or bass, sound. The mid-frequencies range from roughly 500 to 3,000 Hz, where most speech information is carried. High frequencies are from 3,000 to 17,000 Hz.

3.10.1.4 A-Weighted Sound Level

The most commonly used measure of noise level is the A-weighted sound level (dBA). From many experiments with human listeners, scientists have found that the human ear is more sensitive to midrange frequencies than it is to either low or very high frequencies. At the same sound level, midrange frequencies therefore are heard as louder than low or very high frequencies. This characteristic of the human ear is taken into account by adjusting or weighting the spectrum of the measured sound level for the sensitivity of human hearing. The A-weighted sound level is a measure of sound intensity with frequency characteristics that correspond to human subjective response to noise. The A-weighted sound level is accepted by acousticians as a proper noise impact unit for traffic noise.

An understanding of these relationships is helpful in providing a subjective impression of changes in the A-weighted sound level:

- Except in carefully controlled laboratory experiments, an increase of only 1 dB in A-weighted level cannot be perceived;
- Outside of the laboratory, a 3 dB increase in A-weighted level is considered a just-noticeable difference;
- A change in A-weighted level of at least 5 dB is required before any significant change in the noise level in a community is perceived; and
- A 10 dB increase in A-weighted level is subjectively heard as approximately a doubling in loudness, independent of the existing noise level.

3.10.1.5 Sound Level Descriptors

The third basic parameter of environmental noise is its time-varying character. The sound level from any roadway fluctuates from moment to moment as time passes. These fluctuations constitute the time-varying properties of roadway noise.

The sound level descriptor used in this study is L_{eq}. L_{eq} is defined as the continuous A-weighted sound level that, in a given time period, contains the same energy as the actual time-varying sound during that period. L_{eq} has been shown to be a particularly stable descriptor for roadways with low traffic volumes. For traffic noise assessment, L_{eq} typically is evaluated over a 1-hour period of peak traffic. All noise levels determined in this study are L_{eq} over a 1-hour period.

3.10.2 Noise Abatement Criteria

In order to determine that highway noise levels are or are not compatible with various land uses, the FHWA has developed Noise Abatement Criteria (NAC) and procedures to be used in the planning and design of highways. A listing of the NAC for various land uses is presented in Table 3-26.

Table 3-26. Noise Abatement Criteria

Activity Category	L_{eq}	Hourly A- Weighted Sound Level – decibels (dBA)
		Description of Activity Category
A	57 (Exterior)	Lands on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose.
B	67 (Exterior)	Picnic areas, recreation areas, playgrounds, active sports areas, parks, residences, motels, hotels, schools, churches, libraries, and hospitals.
C	72 (Exterior)	Developed lands, properties or activities not included in Categories A or B above.
D	--	Undeveloped lands.
E	52 (Interior)	Residences, motels, hotels, public meeting rooms, schools, churches, libraries, hospitals, and auditoriums.

Source: Part 772 of Title 23 of the *Code of Federal Regulations*.

Traffic noise impacts occur when predicted traffic noise levels either:

- Approach or exceed the FHWA NAC or
- Substantially exceed the existing noise levels.

NCDOT *Traffic Noise Abatement Policy* (June 1996) defines "approaching or exceeding" as any activity category land use with a predicted noise level within 1 dBA of its criteria. Substantial increases are defined as 15 dBA or more where the existing L_{eq} is 50 dBA or less, or 10 dBA or more where the existing L_{eq} is greater than 50 dBA.

3.10.3 Ambient Noise Levels

A noise measurement survey was conducted in the project area on June 27, 2003, to document existing noise levels. Table 3-27 lists the four locations where measurements were taken, the date and times of measurement, the predominant surface, the average A-weighted noise levels (L_{eq}), and the FHWA noise abatement category that applies to the receptor. The locations are shown in Figure 3-1a and Figure 3-1c.

Table 3-27. Noise Measurement Results

Site Number	Location and Distance from NC12	Time (on June 27, 2003)	Predominant Surface	Measured L_{eq} (dBA)	FHWA Noise Abatement Criteria Category and L_{eq}
1	Oregon Inlet Campground 100 ft. (30.5 m) east of NC 12	2:15 – 2:35 PM	Grass	58	'B' 67 L_{eq}
2	Residence 1,150 ft. (350.5 m) west of NC 12	3:25 – 3:45 PM	Grass	48	'B' 67 L_{eq}
3	Residence 100 ft. (30.5 m) west of NC 12	4:05 – 4:25 PM	Grass	64	'B' 67 L_{eq}
4	Residence 500 ft. (152.4 m) west of NC 12	4:30 – 4:50 PM	Grass	52	'B' 67 L_{eq}

[1] Distance was measured from near edge of road to receptor. Sites are shown in Figure 3-1a and Figure 3-1c.

Traffic on NC 12 and Bonner Bridge was the dominant source of noise. There was little interruption or buffers between the roadway and receptors. Noise measurements were recorded for 20-minute periods. The noise meter used was a Larson Davis 820 sound level meter. Accessories included a Larson Davis CAL200 calibrator, a Larson Davis 2560 microphone, and a microphone windshield. The microphone was placed 5 feet (1.52 meters) above the ground. Simultaneous vehicle classification counts were recorded for nearby roadways, as applicable. The data were extrapolated to one-hour volumes for verification of the sample noise measurements and model calibration.

Chapter 4

Environmental Consequences

4.0 Environmental Consequences

The purpose of this chapter is to describe the anticipated community, cultural resource, natural resource, environmental quality, and other effects of the replacement bridge corridor alternatives described in Chapter 2. The two corridor alternatives are:

- Pamlico Sound Bridge Corridor with two possible termini design options in Rodanthe (Curved Rodanthe Terminus and Intersection Rodanthe Terminus), described in Section 2.9; and

- Parallel Bridge Corridor with NC 12 Maintenance Alternatives (Nourishment, Road North/Bridge South, All Bridge, Phased Approach/Rodanthe Bridge [Preferred], and Phased Approach Rodanthe Nourishment), described in Section 2.10.

Where appropriate, the text contrasts the replacement bridge corridor alternatives with the No-Action Alternative.

The chapter is divided into topical discussions in a manner similar to Chapter 3. These sections address the following issues:

- Community Impacts, beginning on page 4-2;

- Environmental Justice, on page 4-28;

- Visual Impacts, beginning on page 4-28;

- Cultural Resources, beginning on page 4-33;

- Parks and Recreation, beginning on page 4-41;

- Coastal Conditions, beginning on page 4-49;

- Natural Systems, beginning on page 4-74;

- Mineral Resources, on page 4-141;

- Air Quality, beginning on page 4-141;

- Noise, beginning on page 4-150;

- Energy, beginning on page 4-156;

- Indirect and Cumulative Impacts, beginning on page 4-158;

- Construction, beginning on page 4-172;

- Relationship between Long-Term and Short-Term Uses/Benefits, beginning on page 4-181; and

- Irreversible and Irretrievable Commitments of Resources, beginning on page 4-181.

4.1 Community Impacts

This section discusses the impacts of the detailed study alternatives, as well as the No-Action Alternative (where appropriate) on various aspects of the project area community. It includes details on home and business relocations as well as impacts to area land use plans, the Coastal Barrier Resources System, community cohesion and accessibility, economics and community services, Oregon Inlet users, underground storage tanks and hazardous waste, and farmland.

4.1.1 Relocations

No relocation of residential or business land uses would occur with the No-Action Alternative. The replacement bridge corridor alternatives would require the relocations shown in Table 4-1.

Table 4-1. Relocations

	Homes	Businesses
Pamlico Sound Bridge Corridor		
• Curved Rodanthe Terminus	6	6
• Intersection Rodanthe Terminus	5	1
Parallel Bridge Corridor		
• With Nourishment	0	0
• With Road North/Bridge South	2	0
• With All Bridge	2	0
• With Phased Approach/Rodanthe Bridge (Preferred)	3	1
• With Phased Approach/Rodanthe Nourishment	0	0

No schools, churches or other community facilities would be displaced with any of the bridge replacement corridor alternatives. With the Parallel Bridge Corridor with Road North/Bridge South and All Bridge Alternatives, a service road would be built to connect traffic to the Rodanthe-Waves-Salvo Community Center (see Section 4.1.6.4).

The North Carolina Department of Transportation (NCDOT) prepared relocation reports (July 22, 2005 and February 5, 2007) reporting the number of homes and businesses displaced, the specific businesses displaced, the value of the displaced homes, the availability of decent, safe, and sanitary replacement housing, and the expected relocation needs (Appendix C). All of the homes and businesses displaced are owner-occupied, with the exception of a tenant-occupied residence displaced by the Parallel Bridge Corridor Phased Approach/Rodanthe Bridge Alternative (Preferred). This alternative also would remove the gas pumps from the gas station (Liberty)

closest to NC 12 and also shorten the canopy of the service station. The gas pumps and canopy associated with another business also would be removed (North Beach Beach Mart). In the case of the North Beach Beach Mart, the structures affected are partially within what is believed to be the NCDOT's NC 12 right-of-way. Impacts to minorities, large families, disabled persons, or others who would have special problems being relocated are not anticipated. No special relocation services would be necessary.

The residential relocations would not cause a housing shortage. Based on coordination with Realtors in the project area, there is adequate decent, safe, and sanitary housing that is expected to be available during the relocation period. Suitable sites for relocating the displaced businesses are also available.

It is the policy of the NCDOT to ensure that comparable replacement housing will be available prior to the construction of state and federally-assisted projects. Furthermore, the North Carolina Board of Transportation has the following three programs to minimize the inconvenience of relocation:

- Relocation Assistance;
- Relocation Moving Payments; and
- Relocation Replacement Housing Payments or Rent Supplement.

With the Relocation Assistance Program, experienced NCDOT staff will be available to assist displacees with information such as availability and prices of homes, apartments, or businesses for sale or rent and financing or other housing programs. The Relocation Moving Payments Program, in general, provides for payment of actual moving expenses encountered in relocation. Where displacement will force an owner or tenant to purchase or rent property of higher cost or to lose a favorable financing arrangement (in cases of ownership), the Relocation Replacement Housing Payments or Rent Supplement Program will compensate up to $22,500 to owners who are eligible and qualify and up to $5,250 to tenants who are eligible and qualify.

The relocation program for the proposed action will be conducted in accordance with the Federal Uniform Relocation Assistance and Real Property Acquisitions Act of 1970 (Public Law 91-646), and the North Carolina Relocation Assistance Act (GS-133-5 through 133-18). The program is designed to provide assistance to displaced persons in relocating to a replacement site in which to live or do business. At least one relocation officer is assigned to each highway project for this purpose.

The relocation officer will determine the needs of the displaced families, individuals, businesses, non-profit organizations, and farm operations for relocation assistance advisory services without regard to race, color, religion, sex, or national origin. The NCDOT will schedule its work to allow ample time, prior to displacement, for negotiations and possession of replacement housing that meets decent, safe, and sanitary standards. The displacees are given at least a 90-day written notice after NCDOT purchases the property. Relocation of displaced persons will be offered in areas not generally less desirable in regard to public utilities and commercial facilities. Rent and sale prices of replacement property will be within the financial means of the families and individuals displaced, and will be reasonably accessible to their places of employment. The relocation officer will also assist owners of displaced businesses, non-profit organizations, and farm operations in searching for and moving to replacement property.

All tenant and owner residential occupants who may be displaced would receive an explanation regarding all available options, such as (1) purchase of replacement housing, (2) rental of replacement housing, either private or public, or (3) moving existing owner-occupant housing to another site (if possible). The relocation officer will also supply information concerning other state or federal programs offering assistance to displaced persons and will provide other advisory services as needed in order to minimize hardships to displaced persons in adjusting to a new location.

The Moving Expenses Payment Program is designed to compensate the displacee for the costs of moving personal property from homes, businesses, non-profit organizations, and farm operations acquired for a highway project. Under the Replacement Program for Owners, NCDOT will participate in reasonable incidental purchase payments for replacement dwellings, such as attorney's fees, surveys, appraisals, and other closing costs and, if applicable, make a payment for any increased interest expenses for replacement dwellings. Reimbursement to owner-occupants for replacement housing payments, increased interest payments, and incidental purchase expenses may not exceed $22,500 (combined total), except under the Last Resort Housing provision.

A displaced tenant may be eligible to receive payment, not to exceed $5,250, to rent a replacement dwelling or to make a down payment, including incidental expenses, on the purchase of a replacement dwelling. The down payment is based upon what the state determines is required when the rent supplement exceeds $5,250.

It is a policy of the state that no person will be displaced by NCDOT's state or federally-assisted construction projects unless and until comparable replacement housing has been offered or provided to each displacee within a reasonable period of time prior to displacement. No relocation payment received will be considered as income for the purposes of the Internal Revenue Code of 1954 or for the purposes of determining eligibility or the extent of eligibility of any person for assistance under the Social Security Act or any other federal law.

Last resort housing is a program used when comparable replacement housing is not available, or when it is unavailable within the displacee's financial means, and the replacement payment exceeds the federal/state legal limitation. The purpose of the program is to allow broad latitudes in methods of implementation by the state so that decent, safe, and sanitary replacement housing can be provided. This program would be implemented, if necessary, as mandated by state law.

4.1.2 Land Use Planning

The Pamlico Sound Bridge Corridor alternatives would be compatible with the *Dare County Land Use Plan* and zoning, the Coastal Area Management Act (CAMA), the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan*, and National Park Service (NPS) plans. The Pamlico Sound Bridge Corridor, however, would likely result in the Pea Island National Wildlife Refuge (Refuge) providing some form of alternative access to the Refuge other than the paved road desired by some Dare County and local municipal officials.

The Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be compatible with the *Dare County Land Use Plan* and zoning. However, the two Phased Approach alternatives (including the Preferred Alternative) may not be compatible with the principles of the CAMA because they require the construction of permanent bridges in locations that are projected to eventually be on the beach and in the ocean. The Parallel Bridge Corridor alternatives also may not be consistent with the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan* or NPS plans. The relocation of NC 12 to the west with the

Road North/Bridge South and All Bridge alternatives would affect important wildlife habitat (see Section 4.7.3). The use of artificial dunes and/or beach nourishment associated primarily with the Nourishment Alternative would not support the natural processes of barrier island dynamics. However, the NPS and US Fish and Wildlife Service (USFWS) will be responsible for determining whether or not the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are consistent with NPS plans and the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan*, respectively. The Refuge's *Comprehensive Conservation Plan* assumes a bridge over Oregon Inlet and a maintained road in the existing NC 12 easement in the Refuge pending NCDOT's decisions on the replacement of Bonner Bridge and the long-term maintenance of NC 12.

The No-Action Alternative would not be consistent with the *Dare County Land Use Plan* and the CAMA. It would be consistent with NPS plans and the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan.*

4.1.2.1 Coastal Area Management Act

As discussed in Section 4.1.2.2, the replacement bridge corridor alternatives would be compatible with the *Dare County Land Use Plan* (except for the preference of Dare County officials on how NC 12 access to Hatteras Island is maintained), so they also would meet the consistency requirement of the CAMA, which requires that any action affecting an area of environmental concern (AEC) be consistent with the local land use plans. However, the two Phased Approach alternatives (including the Preferred Alternative) may not be compatible with the principles of CAMA because they require the construction of permanent bridges in locations that are projected to eventually be on the beach and in the ocean. All of the oceanfront lands in the project area are included in the Ocean Hazard System AEC, which is comprised of three areas: the Ocean Erodible AEC (beaches and any other oceanfront lands that are subject to long-term erosion and significant shoreline changes); the High Hazard Flood AEC (lands subject to flooding, high waves, and heavy water currents during a major storm); and the Inlet Hazard AEC (lands next to ocean inlets). CAMA restrictions on development in Ocean Hazard AECs are found in 15A NCAC 7H.0300 (North Carolina Administrative Code). These restrictions include setback standards to address erosion, minimum elevations for first floor construction to allow for ocean overwash, and regulations to prevent unnecessary loss of oceanfront dunes. Because the Preferred Alternative is projected to eventually be in an Ocean Hazard AEC, a variance may have to be petitioned from the North Carolina Coastal Resources Commission (NCCRC) in order to obtain a CAMA permit (see Section 3.1.3.1). Although they would not involve a structure on the beach, a variance also could be needed for the other Parallel Bridge Corridor Alternatives.

The replacement bridge corridor alternatives also would affect coastal wetlands, and CAMA permits are required for those development activities that take place in coastal wetlands.

Since the No-Action Alternative would not be compatible with the *Dare County Land Use Plan* for the reasons described in Section 4.1.2.2, it also would not meet the consistency requirement of the CAMA.

4.1.2.2 Dare County Land Use Plan

Both the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor are compatible because neither alternative would generate unanticipated growth (either in terms of an increased rate or an increased intensity of development) nor affect the character of future growth. Such growth is not anticipated because:

- A bridge in either one of the replacement bridge corridors would replace an existing bridge, and current plans assume a continuation of road access between Bodie and Hatteras islands.

- The availability of undeveloped land considered environmentally suitable for development on Hatteras Island is limited.

- The type and intensity of future development is constrained by Dare County zoning and land use planning, the availability of water, and reliance on septic tanks.

In addition, both of the replacement bridge corridor alternatives would be compatible with the *Dare County Land Use Plan* because they would ensure that NC 12 continues to connect to Hatteras Island. Dare County officials have, however, indicated a desire to retain a paved NC 12 through the Refuge as a part of replacing Bonner Bridge. The Pamlico Sound Bridge Corridor would bypass the Refuge, and although Refuge officials intend to maintain access to the Refuge, it is unlikely to be a paved road.

Paved shoulders on bridges (8 feet [2.4 meters]) and on roadways (4 feet [1.2 meters]) would be a part of all the replacement bridge corridor alternatives, facilitating NC 12's use by bicycles.

The No-Action Alternative would not be consistent with the *Dare County Land Use Plan's* support of new transportation and economic development projects. The removal of bridge access to Hatteras Island and loss in travel capacity likely would diminish the expected future permanent population, as well as the number of visitors to Hatteras Island, the Cape Hatteras National Seashore (Seashore), and the Refuge.

4.1.2.3 National Park Service Plans

The Pamlico Sound Bridge Corridor would not affect existing NPS facilities or operations either directly by displacement or indirectly by visual impacts (see Section 4.3) or noise (see Section 4.10). No new facilities or activities are planned by the NPS near the Pamlico Sound Bridge Corridor. The Pamlico Sound Bridge Corridor, in the long-term, would be compatible with the NPS's desire of supporting the natural processes of barrier island dynamics, since NCDOT would no longer be required to maintain NC 12 on Hatteras Island within the Seashore and the Refuge in order to maintain traffic between Bodie and Hatteras islands.

Although the Pamlico Sound Bridge Corridor would bypass the portion of the Seashore and Refuge, the USFWS and NPS would maintain some type of access to this portion of the Seashore and the Refuge for recreational users.

The Parallel Bridge Corridor would not affect existing NPS facilities or operations on Bodie Island. Facilities within the Refuge and Seashore north of Rodanthe would be affected by the Parallel Bridge Corridor alternatives (including the Preferred Alternative), as described in Section 4.5. No new facilities or activities are planned by the NPS near the Parallel Bridge Corridor on Hatteras Island.

The Parallel Bridge Corridor with Nourishment, with Phased Approach/Rodanthe Nourishment, and with Road North/Bridge South alternatives would not be compatible with the NPS's desire of supporting the natural processes of barrier island dynamics. The Road North/Bridge South Alternative includes the construction of three new dunes as the shoreline continues to erode, the first being in year 2030. The Parallel Bridge Corridor with All Bridge and Phased Approach/Rodanthe Bridge (Preferred) alternatives would be compatible with this NPS desire.

The NPS will determine if the bridge replacement corridor alternatives would impair (harm) park resources or values under the terms of the National Park Service Organic Act (16 *United States Code* [USC] 1) and the 1978 amendment to the National Park System General Authorities Act of 1970 (16 USC 1a-1) (see Section 3.1.3.3). Also, NPS will be responsible for determining whether or not the detailed study alternatives (including the Preferred Alternative) are consistent with NPS plans.

The No-Action Alternative would be compatible with Seashore plans assuming the associated ferry service terminates at the emergency ferry terminal in Rodanthe and, like the Pamlico Sound Bridge Corridor, bypasses the Refuge. If the ferry terminal were placed at the north end of Hatteras Island, ongoing protection and maintenance of NC 12 would be required.

4.1.2.4 Pea Island National Wildlife Refuge Comprehensive Conservation Plan

The *Comprehensive Conservation Plan* for the Refuge was published in September 2006. The *Comprehensive Conservation Plan* discourages changes to the location of NC 12 within the Refuge as it would affect wildlife habitat. The Pamlico Sound Bridge Corridor would be compatible with the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan*, even though the document reflects planning strategies with NC 12 and Bonner Bridge in their current positions. The Pamlico Sound Bridge Corridor would bypass the Refuge and, therefore, would not affect the Refuge's natural resources. The Refuge plan states that if paved road access to the Refuge is altered or eliminated as a result of NCDOT's replacement of Bonner Bridge, the plan may require revision to reflect new methods of access. The Pamlico Sound Bridge Corridor, however, would likely result in the Refuge providing some form of alternative access to the Refuge rather than the paved road desired by some Dare County and local municipal officials.

The USFWS will be responsible for determining whether or not the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are consistent with USFWS plans; however, based on statements from the USFWS during their participation on the National Environmental Policy Act (NEPA)/Section 404 Merger Team and in written comments on the Supplemental Draft Environmental Impact Statement (SDEIS) and the Supplement to the SDEIS (SSDEIS), the Parallel Bridge Corridor may not be compatible with the *Pea Island National Wildlife Refuge Comprehensive Conservation Plan*. The Refuge's *Comprehensive Conservation Plan* assumes a bridge over Oregon Inlet and a maintained road in the existing NC 12 easement in the Refuge pending NCDOT's decisions on the replacement of Bonner Bridge and the long-term maintenance of NC 12. With the two Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative), as well as the Nourishment Alternative, NC 12 would be retained in its existing easement through the Refuge, as assumed in the *Comprehensive Conservation Plan*. With the All Bridge Alternative and the Road North/Bridge South Alternative, NC 12 would be on a new alignment west of NC 12's current location through the Refuge, affecting wildlife habitat managed by the Refuge as described in Section 4.6.8. The Nourishment Alternative may not be compatible with Refuge objectives. Although the alignment of NC 12 through the Refuge would not change, the nourishment and dunes that allow NC 12 to remain in place would maintain the shoreline artificially.

The two Phased Approach alternatives (including the Preferred Alignment) differ from the other Parallel Bridge Corridor alternatives in that they would stay within the existing NC 12 easement with one exception. The Phased Approach/Rodanthe Nourishment Alternative includes nourishment to maintain NC 12 in Rodanthe that would affect beaches at the southern end of the Refuge. The selected management alternative contained in the Refuge's *Comprehensive Conservation Plan* assumes that NC 12 remains within the existing easement in its current form

pending a decision by the NCDOT on how to replace Bonner Bridge. The two Phased Approach alternatives (including the Preferred Alternative) are different from the existing road in that they are elevated, with the bottom of the superstructure at a height of 25 feet (7.6 meters) above mean high water. Also, ultimately as the shoreline erodes, most of the bridges associated with this alternative would no longer be in the Refuge, but rather would be in the ocean east of the Refuge.

Effects on Refuge facilities caused by the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are described in Section 4.5. No new facilities or activities are planned by the Refuge near the Parallel Bridge Corridor on Hatteras Island.

As stated previously, the USFWS will be responsible for determining whether or not the Phased Approach/Rodanthe Bridge Alternative (Preferred) is consistent with both the Refuge's mission and plans, including the *Comprehensive Conservation Plan*, as well as the provisions of the National Wildlife Refuge System Improvement Act of 1997 (see Section 3.1.3). A compatibility determination is not required because the Preferred Alternative falls within the terms of the easement permit.

The No-Action Alternative would be compatible with Refuge plans assuming the associated ferry service terminates at the emergency ferry terminal in Rodanthe and, like the Pamlico Sound Bridge Corridor, bypasses the Refuge. If the ferry terminal were placed at the north end of Hatteras Island, ongoing protection and maintenance of NC 12 would be required.

4.1.3 Coastal Barrier Resources System

The replacement bridge corridor alternatives are not within an area included in the Coastal Barrier Resources System (CBRS). In addition, because the proposed project would consist of the replacement of an existing bridge, as well as an existing road in the case of the Parallel Bridge Corridor, project area development trends would not be altered; therefore, the project would not encourage development in a CBRS area.

4.1.4 Community Cohesion and Accessibility

4.1.4.1 Community Cohesion

Neither of the Pamlico Sound Bridge Corridor alternatives, as well as the Parallel Bridge Corridor with Nourishment, Road North/Bridge South, and All Bridge alternatives, would affect the cohesion of the seven communities on Hatteras Island. The existing relationships among the communities of Hatteras Island with Bodie Island and the mainland would be maintained. Access on and off the island, including access to jobs, community services, and the continued delivery of goods and services from the mainland, would be maintained.

Both of the Parallel Bridge Corridor with the Phased Approach alternatives would impact community cohesion as a result of the presence of bridges in Rodanthe. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would have the greatest affect on community cohesion of the two alternatives.

The Phased Approach/Rodanthe Nourishment Alternative would cause neighborhood impacts in Rodanthe. A permanent approach structure and fill would extend approximately 0.22 mile (0.35 kilometer) south of the Refuge boundary into Rodanthe to near Corbina Drive, creating a visual barrier between the homes on either side of NC 12. Vehicular access would be maintained to the

homes along NC 12 in this area by one-lane, one-way frontage roads on either side of the NC 12 bridge with a cross-over just south of the Refuge boundary. Access for pedestrians would be provided under the NC 12 bridge, except for in the area of the approximately 600 feet (183 meters) of the approach roadway that would be on fill.

The Phased Approach/Rodanthe Bridge Alternative (Preferred) would have the greatest effect on the cohesion of the Rodanthe community. The introduction of an elevated structure, with frontage roads extended from north of Sudie Payne Road (see Figure 2-21) to the Refuge boundary, would cause substantial visual impacts (see Section 4.3) and essentially bisect the community, creating distinct and separate Pamlico Sound and Atlantic Ocean neighborhoods. Although frontage road motorists would be provided three crossover points at America Drive, Cross of Honor Way (near Seagull Street), and just south of the Refuge border to cross under the bridge, the bridge would still create an NC 12 bypass of the northern part of the Rodanthe community. Several businesses, including a gas station that relies on business from NC 12 traffic, would be bypassed. Traffic would have to travel a circuitous route to access properties on either side of the bridge. The crossover point at America Drive is just north of the sole area of commercial businesses in this part of Rodanthe. It was placed at this point, in part, to minimize circuitous travel by the customers of these businesses. Again, pedestrians would be able to walk under the NC 12 bridge, except for the area of the approach roadway that would be on fill.

The No-Action Alternative would not affect internal community cohesion on Hatteras Island, but the eventual loss of road access to Bodie Island across Oregon Inlet would isolate the communities on Hatteras Island from the larger community of Dare County. With the No-Action Alternative, two routes to the mainland would be available. The most direct route would be via the new ferry service incorporated into the No-Action Alternative. Use of this service, however, would add at least 80 minutes each way to a trip between Hatteras Island and the mainland. Eighty minutes was the approximate time required for loading, unloading, and travel for a one-way trip across Oregon Inlet via the emergency ferry service provided from October 1990 to February 1991 when Bonner Bridge was closed. It does not include waiting time prior to the start of loading.

A less desirable alternative would be via the existing ferry service at the south end of Hatteras Island. A one-way trip from Rodanthe, the northernmost community on Hatteras Island, to the mainland would require a 34-mile (54.4-kilometer) ride on NC 12, as well as two ferry trips lasting a total of three hours. The final ferry trip would terminate in Hyde County. Additional travel then would be required to reach mainland Dare County.

4.1.4.2 Accessibility

The replacement bridge corridor alternatives would maintain road access between Hatteras Island and Bodie Island and mainland Dare County. Access for visitors to the Refuge and the Hatteras Island portion of the Seashore would be maintained, but in the case of the Pamlico Sound Bridge Corridor, the access would not likely be on a paved road. Although the Pamlico Sound Bridge Corridor would bypass the portion of the Seashore north of Rodanthe and the Refuge, the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge and this portion of the Seashore for recreational users. However, the method of access likely would be something different than a paved road between Rodanthe and Oregon Inlet.

The Parallel Bridge Corridor alternatives would maintain road access to the Refuge and its beaches. Refuge access would be slightly more limited with the Road North/Bridge South Alternative, but the All Bridge Alternative and the two Phased Approach alternatives (including the Preferred Alternative) would limit Refuge access to three points and two points, respectively. Access to homes and businesses in Rodanthe also would be maintained by all the Parallel Bridge

Corridor alternatives, although the two Phased Approach alternatives (including the Preferred Alternative) would change the existing access in Rodanthe. Vehicular access would be maintained to the homes along NC 12 in this area by one-lane, one-way frontage roads on either side of the NC 12 bridge with a cross-over just south of the Refuge boundary. Pedestrians would be able to walk under the NC 12 bridge, except in the area of the approximately 600 feet (183 meters) of the approach roadway that would be on fill.

Fishing catwalks would not be placed on a new bridge with either of the Pamlico Sound Bridge Corridor alternatives or the Parallel Bridge Corridor with Nourishment, Road North/Bridge South, and All Bridge alternatives. The NCDOT would work with USFWS, NPS, Dare County, and other appropriate agencies to decide how to restore some kind of fishing access at the north end of Hatteras Island. Options for retaining fishing opportunities offered by the catwalks include either maintaining a part of Bonner Bridge as a fishing pier or constructing a "boardwalk" on top of the terminal groin. To maintain a portion of Bonner Bridge as a fishing pier, some government body or nongovernmental organization would have to take responsibility for pier operation, maintenance, and liability.

Catwalks probably would not be placed on the new Oregon Inlet bridge for either of the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative). However, fishing access could be provided by leaving the traffic maintenance bridge in place as a fishing pier. This opportunity also could be used with the Nourishment Alternative (see Section 4.5.3.2). A traffic maintenance bridge is not needed with the other alternatives, and thus leaving one in place is not an option with the other alternatives.

The No-Action Alternative would dramatically limit the accessibility of Hatteras Island to residents, visitors, workers, and off-island goods and services once Bonner Bridge reaches the end of its service life and is demolished. The limited ferry service that would be provided would offer space for 900 trips per day across Oregon Inlet. In addition, the No-Action Alternative would deliver travelers to a section of roadway that frequently is overwashed by the ocean and that requires expensive and repetitive maintenance. The 2002 annual average daily traffic across Bonner Bridge was 5,400 vehicles per day (vpd). It is expected that by 2025 annual average daily traffic would be 9,600 vpd with a replacement bridge in either replacement bridge corridor. Other than the disruption of travel across Oregon Inlet, routes from NC 12 to various Seashore and Refuge facilities and activities would not be affected with the No-Action Alternative.

4.1.5 Economics

Potential direct impacts of both the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor alternatives (including the Preferred Alternative) include the displacement of businesses, lost tax base for Dare County associated with the land for the project right-of-way in Rodanthe, the economic impact of changed access to the Refuge with the Pamlico Sound Bridge Corridor, and the risk of a new breach opening within the Refuge, as well as the economic impact of such a breach.

The No-Action Alternative would not displace any businesses nor directly affect the tax base for Dare County by moving private lands into the public domain. The No-Action Alternative would have several adverse impacts on the economy of the island. It would limit the variety of goods and services available to island residents and visitors and would increase travel time to and from the island, which could result in a decline in the tourism-related sectors of the area's economy.

Access to the Oregon Inlet Fishing Center and Marina would not be affected during construction of the project. The US Army Corps of Engineers' (USACE) maintained channel used by boaters

from the Marina would not be blocked. Thus the project is not expected to affect the use or annual sales of the facility.

4.1.5.1 Business Displacement

The Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus would displace six businesses. The Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus would displace one business.

The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would displace a commercial building containing one business. In addition, the gas pumps closest to NC 12 at the Liberty service station would be removed, and the canopy of the station also would be shortened. The gas pumps and canopy at the North Beach Beach Mart also would be removed. A small amount of new right-of-way (approximately 7 feet [2.1 meters]) would be required along most of the length of both Phased Approach alternatives (including the Preferred Alternative) in Rodanthe (though no new right-of-way would be obtained within the historic district). Additional new right-of-way also is required for a short distance at the intersection of the frontage roads with existing NC 12 at the southern end of the NC 12 bridge.

The other Parallel Bridge Corridor alternatives and the No-Action Alternative would not displace any businesses.

All of the displacements for all of the alternatives would be in Rodanthe, and any business displaced would be relocated. According to the relocation reports, suitable sites are available to relocate the displaced businesses. Minor short-term impacts on business activity in Rodanthe might occur because of reduced access resulting from construction activity. Short-term increases in local employment and income earnings related to construction labor also could be anticipated.

Long-term changes in access and traffic flow at businesses would occur only with the Phased Approach/Rodanthe Bridge Alternative (Preferred). NC 12 would bypass approximately 13 businesses, including the following types of businesses that rely at least partially on tourists passing by for their customer base: restaurant; gas station/convenience store; gift shop; real estate office; surf shop; and seafood/produce market. Access would be provided via a frontage road. Rental properties along the Pamlico Sound near the Rodanthe terminus could be seen as less desirable by vacationers because of impacts to views with all alternatives.

4.1.5.2 Tax Base

With the exception of the Parallel Bridge Corridor with Nourishment Alternative, the tax base of Dare County would be reduced by all of the replacement bridge corridor alternatives, because the land and buildings purchased for the project right-of-way in Rodanthe would be removed from the county tax base. However, the tax base loss associated with any of the replacement bridge corridor alternatives would be a fraction of one percent of the county's total tax base. The annual tax revenue loss to the Dare County general fund would be the highest with the two Phased Approach alternatives at approximately $182,700 for the Phased Approach/Rodanthe Bridge Alternative (Preferred) and $37,500 for the Phased Approach/Rodanthe Nourishment Alternative. The tax revenue loss would be lower for the other alternatives at approximately $14,100 for the Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus, $10,500 for the Intersection Rodanthe Terminus, and $1,500 for the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives. No private land would be purchased, so no tax base is lost with the Parallel Bridge Corridor with Nourishment Alternative.

4.1.5.3 Effect of Changed Access

The replacement bridge corridor alternatives would permit the continued use of the Hatteras Island portion of the Seashore, as well as associated commercial and tourism related services. The replacement bridge corridor alternatives also would allow for anticipated growth in Rodanthe. The Parallel Bridge Corridor would retain paved road access in the Refuge, although that access would be limited to three locations with the All Bridge Alternative and two locations with the two Phased Approach alternatives (including the Preferred Alternative) (see Section 4.5.3.1).

The Pamlico Sound Bridge Corridor would bypass the portion of the Seashore north of Rodanthe and the Refuge, but the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge and this portion of the Seashore for recreational users. However, the method of access likely would be something different than a paved road between Rodanthe and Oregon Inlet. The NCDOT likely would seek and accept an invitation to participate in USFWS and NPS efforts to develop their own access program.

The potential economic impact of eliminating paved road access to the Seashore north of Rodanthe and Refuge with the Pamlico Sound Bridge Corridor on Dare County was assessed. On average, these losses are not likely to have a major economic impact on the Outer Banks/Dare County area. Some individual businesses, however, would be more directly affected, and could suffer serious losses. The basis for this finding is described in the paragraphs that follow. The assessment is also documented in *Bonner Bridge Replacement Economic Impact Report* (Parsons Brinckerhoff Quade & Douglas, Inc., July 2005). The analysis found that the loss of paved road access would cause 9 percent of Refuge visitors not to visit the Outer Banks. The 9 percent includes surveyed visitors that said they would not visit the Refuge without paved road access and had no other location on the Outer Banks to participate in the activity for which they currently use the Refuge. Of the visitors surveyed, 12.6 percent said they would still visit the Refuge with alternate access, but there were no other locations on the Outer Banks to participate in the activity for which they currently use the Refuge. This group makes up 51,600 to 67,100 (12.9 percent of the estimated 400,000 to 520,000) annual visitors to the Refuge. These visitors would need to be served by the USFWS/NPS's alternate access program, or the economic impact could be worse than described.

Direct Impacts

Direct economic impacts associated with the loss of paved road access can be measured as the loss of visitors' expenditures resulting from the change. The Travel Industry Association of America (TIA), which conducts extensive surveys of tourist travel behavior and expenditure patterns throughout the Unites States, has published estimates of average visitor expenditures and duration of tourist visits in North Carolina. The TIA's most recent visitor expenditure data for North Carolina (TIA, 2004) indicate that out-of-state tourists visiting North Carolina spend an average of $332 per visit; North Carolina resident tourists average $221 per visit. On average, 68 percent of North Carolina tourist trips involve at least one overnight stay, with 46 percent staying in hotels, motels, or other commercial lodgings. The average duration of a tourist visit in North Carolina is 2.3 nights. Using this information, a range of between 400,000 and 520,000 visitors per year to the Refuge (Parsons Brinckerhoff Quade & Douglas, Inc., July 2005), and the percent of in-state and out-of-state visitors to the Refuge derived from the Refuge visitors study (see Table 3-11) conducted for this assessment, it was estimated that Refuge visitor expenditures vary from $114 million to $149 million annually (see Table 4-2). Key results of the visitors study are presented in Section 3.5.2.4 and are documented in full in *Pea Island National Wildlife Refuge Visitors' Utilization Study* (Parsons Brinckerhoff Quade and Douglas, Inc., April 2005).

Table 4-2. Refuge Visitor Expenditures

Total Refuge Visitor Estimates	Estimated In-State Refuge Visitors		Estimated Out-of-State Refuge Visitors		Estimated Visitor Expenditures (millions)		
	%	Number	%	Number	In-State	Out-of-State	TOTAL
400,000	41.7	166,800	58.3	233,200	$36.9	$77.4	$114.3
520,000	41.7	216,840	58.3	303,160	$48.0	$100.7	$148.7

The expenditures in Table 4-2 do not reflect the exclusive economic impact of the Refuge. Most visitors to the Refuge come to the Outer Banks for multiple purposes, only one of which is to visit the Refuge. Moreover, Refuge visitors have, in many cases, alternatives to the Refuge in which to conduct their activities, which is reflected in the results of the Refuge visitors study conducted for this assessment. Also, the survey found that even without paved road access, the Refuge would be used. Expenditures most likely lost would be those of visitors who said in the survey that they would not return to the Refuge without paved road access (see Table 3-10) and do not have reasonable alternative places locally to pursue their activities (see Table 3-11).

To determine this share of total Refuge visitors, a cross tabulation of the results from the visitors study has been made as follows:

Other locations to conduct activity	Still would visit PINWR: Yes	Still would visit PINWR: No	
Yes	47.56%	32.24%	79.8%
No	12.04%	8.16%	20.2%
	59.60%	40.40%	

Note: Cell percentages assume independence between the row and column variables.

Approximately 9 percent of the Refuge visitors interviewed satisfy both criteria—that is, they would not visit the Refuge without paved road access, and they do not have alternative locations where they could engage in their activity. This result suggests that the percentage of lost visitor expenditures is about 9 percent of the total Refuge visitor expenditures. For purposes of this assessment, it was assumed that 10 percent of total Refuge visitor expenditures would be "lost" to the Outer Banks region. The slight upward rounding reflects a somewhat higher loss as alternative locations prove to be unsatisfactory for a small number of Refuge visitors over time, as well as the possibility that those who said they would continue to use the Refuge might do so at a lesser frequency.

Given the $114 million and $149 million estimate of total annual visitor expenditures at current levels of visitation and the 10 percent factor, lost visitor spending would range from $11.4 million to $14.9 million annually without paved road access (see Table 4-3). These visitor expenditure loss estimates may be assumed to comprise the direct economic impacts of Refuge visitors, measured in terms of additional final sales.

Table 4-3. Economic Loss from No Paved Road Access to the Pea Island National Wildlife Refuge

	Estimated lost direct Refuge spending (millions)	Multipliers			Economic Loss		
		Output (final sales) multiplier[1]	Earnings multiplier[2]	Employ-ment multiplier[3]	Total lost final sales (millions)	Total lost earnings (millions)	Total lost employ-ment
Eating and drinking places	$3.8-$5.0	1.4914	0.4016	25.5	$5.7-$7.5	$1.5-$2.0	97-128
Hotels and other lodgings	$3.8-$5.0	1.5306	0.3873	17.6	$5.8-$7.7	$1.5-$1.9	67-88
Other retail	$3.8-$5.0	1.4990	0.4193	20.6	$5.7-$7.5	$1.5-$1.9	78-103
TOTAL LOSS	**$11.4-$15.0**	**--**	**--**	**--**	**$17.2-$22.7**	**$4.5-$5.8**	**242-319**

Bureau of Economic Analysis (BEA) multiplier definitions:

[1] Total dollar change in output (final sales) for all industries that results from a $1 change in output delivered to final demand in the table row industry.

[2] Total dollar change in earnings of households employed for all industries that results from a $1 change in output delivered to final demand in the table row industry.

[3] Total change in number of jobs for all industries that results from a $1 million change in output delivered to final demand in the table row industry.

Secondary Impacts

Secondary, or multiplier impacts include indirect and induced effects. Indirect effects arise from the multiple rounds of purchases by businesses to supply needed customers. Induced effects arise from the additional rounds of consumer spending by workers who earn wages. Thus, every tourist dollar spent triggers additional rounds of expenditures. For example, a dollar spent on restaurant meals would generate spending by restaurant establishments on items or services (inputs) such as food, transportation, building maintenance and operation, and labor. Not all of these inputs would be obtained locally, however. Expenditures for items such as food would largely "leak out" to areas outside of the region, lessening the overall economic benefits from final demand spending, such as tourist spending.

Input-output analysis is typically used to evaluate these secondary impacts. For state and county level analyses, a commonly used methodology is the Regional Input-Output Modeling System (RIMS) II Methodology. RIMS II uses the US Department of Commerce, Bureau of Economic Analysis' (BEA) national Input-Output table to estimate these effects at small area levels. Adjustments are made to the national Input-Output tables to reflect the leakages characteristic of

small, open economies. The RIMS II system provides industry specific multipliers, which when applied to direct impacts for that industry, generates estimates of the change across all industry sectors in total output (final demand sales), earnings, and employment resulting from a dollar increase (or decrease) in final demand sales.

Total economic losses resulting from the loss of paved road access to the Refuge may be measured as the sum of direct and indirect impacts.

Utilizing a typical RIMS II multiplier set for an ocean-front community (i.e., RIMS II multipliers for St. Lucie County, Florida), it is thus possible to estimate the total (direct and secondary) annual economic losses resulting from the estimated reductions in Refuge tourism spending. An additional assumption is that, of Refuge visitor expenditures, approximately one-third are for hotels and other lodging places, one-third for restaurants and other eating and drinking places, and one third for miscellaneous retail spending. The results of the RIMS II analysis for lost sales, earnings, and employment for the change in Refuge access is shown in Table 4-3.

An additional indicator of economic loss would include the fiscal impacts, i.e., the impact on Dare County and state tax revenues. Fiscal impacts are shown in Table 4-4.

Table 4-4. Fiscal Impacts from No Paved Road Access to the Pea Island National Wildlife Refuge

Tax type	Tax rate	Tax base	Reduction in tax base (millions)	Tax revenue loss
NC Sales tax	7%	Retail sales	$17.2-$22.7	$1.2-$1.6 million
Dare County Prepared Food and Beverage Tax	1%	Prepared food and beverages	$5.7-$7.5	$57-$75 thousand
Dare County Room Occupancy Tax	3%	Hotel and room lodging sales	$5.8-$7.7	$174-$231 thousand
Dare County Tourism Development Tax (general)	1%	Hotel and room lodging sales	$5.8-$7.7	$58-$77 thousand
Dare County Tourism Development Tax (for beach nourishment)	1%	Hotel and room lodging sales	$5.8-$7.7	$58-$77 thousand
TOTAL LOCAL	--	--	**--**	**$347-$460 thousand**
TOTAL STATE and LOCAL	--	--	**--**	**$1.5-$2.1 million**

On average, these losses are not likely to have a major economic impact on the Outer Banks/Dare County area. For example, total estimated lost employment (242 to 319 jobs) is approximately 2 percent of total private sector Dare County employment of 12,539 (2001), as reported by the Census Bureau. Paid employment, as defined by the Census Bureau, consists of full- and part-time employees, including salaried officers and executives of corporations, who are on the payroll in the pay period that includes March 12. Included are employees on paid sick leave, holidays,

and vacations; not included are proprietors and partners of unincorporated businesses. Many of the lost jobs would likely be seasonal and are not included in the Census totals. Lost income would be about the same small percent. Tax revenue effects would be similarly small. Total Dare County Occupancy Tax Receipts were about $13 million in 2004. Lost tax receipts would comprise about 2.5 percent of the total for Dare County. Lost state sales taxes are a much smaller percentage—less than 0.03 percent of the $4.6 billion gross sales taxes collected in North Carolina in 2004.

Some individual businesses would be more directly affected, and could suffer serious losses. Such businesses would include shops closest to the Refuge, including in particular businesses that rent fishing, birding, or other beach recreational equipment.

No-Action Alternative

Bonner Bridge serves as a supply line for Hatteras Island. The No-Action Alternative would have several adverse impacts on the economy of the island. The variety of goods and services available to island residents and visitors would be more limited than at present, and the prices of available items would become more costly because of reduced accessibility. Commerce between Hatteras Island and the rest of Dare County—and even the region—would be reduced. Employment opportunities for Hatteras Island residents elsewhere in the county and region would be diminished, as would employment opportunities for nonresidents on Hatteras Island. Commercial and residential construction on the island would be curtailed.

The No-Action Alternative also would make travel more difficult for Dare County visitors to Hatteras Island, the entire Hatteras Island portion of the Seashore, and the Refuge. Visitor levels would be affected by both the lack of capacity and the additional time it would take to cross Oregon Inlet, and the increased travel time would discourage day trips. Potential visitors might choose to visit other attractions outside the county. This disruption, in turn, could result in a decline in the tourism-related sectors of the area's economy. Because of the area's economic dependence on tourism and its related service industries, the loss of access could adversely affect the general economic strength of the Hatteras Island communities and Dare County.

4.1.5.4 Effect of a Storm-Related Breach of NC 12

As indicated in Section 3.6.3.4, the potential exists for a storm-related breach to occur in Hatteras Island within the Refuge between now and 2060 (see Figure 2-21), with the storm with the right characteristics to create a breach occurring only once in that time period. Based on the opinions of the expert panel described in Section 3.6.3.4 of, the location most likely for a breach to occur would be at the southern end of the Refuge (Site 3). A breach at this location would only disrupt travel with the Parallel Bridge Corridor with Nourishment and with Phased Approach/Rodanthe Nourishment alternatives. There is also the potential for a deep breach near the terminal groin (Site 5). As discussed in Section 3.6.3.4, access to Hatteras Island would not likely be affected by a breach at this location with the Pamlico Sound Bridge Corridor and the two Phased Approach alternatives (including the Preferred Alternative) (unless a breach occurred prior to implementation of Phases II and III). However, access to the northern tip of Hatteras Island would be lost with the Pamlico Sound Bridge Corridor. It would take three to six months to close a breach at the southern end of the Refuge, during which time travel to Hatteras Island would be limited to an emergency ferry service provided by NCDOT between Hatteras Island at Rodanthe and the mainland at Stumpy Point. A deep breach near the terminal groin would be difficult to close with sand. The potential economic impact of a breach at this location was assessed.

Formation of a breach in the Refuge would temporarily cut off access (except for limited ferry service) to Hatteras Island, including to all the private and public tourism destinations on Hatteras Island (with the probable exception of the Refuge itself, given that the most likely breach location would be at the southern end of the Refuge). Given that a breach could occur at different times of the year, and could take three to six months to close, economic costs were estimated for a low, high, and medium tourism month.

The economic assessment found that direct and secondary impact (measured as a reduction in retail sales) of a breach open for three months would be $5.7, $46.3, and $146.7 million in the off-peak, middle, and peak seasons, respectively. A six month breach covering the middle and peak six months would result in reductions in retail sales of $193.0 million. The job loss with a breach in the peak three months was estimated to be 30,000 person months. The combined state income and sales tax loss, Dare County occupancy tax loss, and Dare County food and beverage sales loss was estimated to be $16.7 million for three months in the peak season and $21.1 million for six months over the six-month middle and peak seasons.

Methodology

The impact assessment in this section considers the impacts of several "breach scenarios." The scenarios reflect uncertainty in the time of year during which a breach might occur, and the expected duration to close a breach. The economic findings of the former—when the breach might occur—varies substantially because the seasonal variation in economic activity in Dare County—particularly on the Outer Banks—which more than Dare County in general, caters to tourist activity. The scenarios are as follows:

- Seasonal variation: peak, off peak, and middle seasons.
- Time to repair: one month; three months.

Direct Economic Impacts

The Outer Banks Chamber of Commerce estimates that approximately 25 percent of total Dare County economic activity is on Hatteras Island. The Chamber of Commerce also estimates that about 20 percent of Dare County restaurant receipts and 29 percent of the gross occupancy receipts (primarily from rental cottages, with some from hotels on the island) are earned on Hatteras Island.

Using these estimates, combined with total measures of Dare County economic activity provided by the Outer Banks Chamber of Commerce, Hatteras Island monthly economic activity across various measures is estimated in Table 4-5. The measures selected are those that likely would be substantially affected by a breach.

The next step is to estimate the amount of Hatteras Island economic activity that can be attributed to tourist activity, as distinct from the economic impacts that might be felt by the permanent population, in the form of increased transportation costs, for both personal and goods related transport.

A reasonable way to estimate this is to look at the difference between off-peak times and other times. The off-peak economic activity reflects the normal activities of residents and businesses, rather than the flow of tourists and visitors to the island. The increment can be assumed to be a reasonable approximation of the economic increment resulting from tourist and visitor activity.

The seasonal (i.e., tourism related) economic activity is estimated in Table 4-6. Incremental or seasonal impacts are measured relative to February, the lowest activity month.

Table 4-5. Hatteras Island Share of Retail, Occupancy, and Food and Beverage Sales

	Season	Gross Retail Sales (millions, 2004)		Gross Occupancy Receipts (millions, 2004)		Food and Beverage Sales (millions, 2004)	
		Dare County	Hatteras Island Share (25%)	Dare County	Hatteras Island Share (29%)	Dare County	Hatteras Island Share (20%)
January		$81.26	$20.32	$1.69	$0.49	$5.23	$1.05
February	Off	$55.11	$13.78	$1.43	$0.41	$5.54	$1.10
March	Off	$51.88	$12.97	$2.66	$0.77	$7.05	$1.41
April	Off	$72.16	$18.04	$8.13	$2.36	$11.34	$2.27
May		$88.34	$22.09	$15.57	$4.52	$14.45	$2.89
June		$108.17	$27.04	$43.77	$12.69	$23.19	$4.64
July	Peak	$173.40	$43.35	$77.49	$22.47	$28.90	$5.78
August	Peak	$237.98	$59.50	$68.65	$19.91	$25.89	$5.18
September	Peak	$218.15	$54.54	$22.89	$6.64	$16.84	$3.37
October	Mid	$135.90	$33.98	$10.93	$3.17	$12.75	$2.55
November	Mid	$91.00	$22.75	$5.06	$1.47	$8.04	$1.61
December	Mid	$77.25	$19.31	$1.34	$0.39	$6.84	$1.37
TOTAL		**$1,390.60**	**$347.67**	**$259.61**	**$75.29**	**$166.06**	**$33.22**

Table 4-6. Hatteras Island Seasonal Retail, Occupancy, and Food and Beverage Sales

	Incremental (Seasonal) Gross Retail Sales (millions)	Incremental (Seasonal) Gross Occupancy Receipts (lodging place receipts) (millions)	Incremental (Seasonal) Food and Beverage Sales (millions)
Peak Season	**$116.05**	**$47.79**	**$11.03**
• July	29.57	22.06	4.68
• August	45.72	19.50	4.08
• September	40.76	6.23	2.27
Mid-Season	**$34.70**	**$3.82**	**$2.23**
• October	20.20	2.76	1.45
• November	8.97	1.06	0.51
• December	5.53	0.00	0.27
Off-Peak Season	**$4.26**	**$0.44**	**$1.48**
• February	0.00	0.08	0.00
• March	0.00	0.00	0.31
• April	4.26	0.36	1.17

Note: Incremental impacts measured relative to February, the lowest activity month.

The information in Table 4-6 can be used to estimate the direct economic losses of a breach for the six scenarios considered. These estimates are presented in Table 4-7. Economic losses consist of reduced retail sales; gross occupancy receipts and food and beverage sales are a subset of gross retail sales – the three columns in Table 4-6 are thus not additive, but indicate sub-sector impacts.

Table 4-7. Breach Direct Economic Impact by Season

	Peak Season (millions, 2004 dollars)	Off-Peak Season (millions, 2004 dollars)	Mid-Season (millions, 2004 dollars)
1 month breach (average)	$38.68	$1.42	$11.57
3 month breach	$116.05	$4.26	$34.70

Secondary Economic Impacts

Multiplier and total effects (i.e., direct plus secondary impacts), can be estimated based on the direct reduction in retail sales. Multipliers must be applied carefully in this case; however, it is unclear to what extent Hatteras Island businesses can satisfy input requirements, as compared with those inputs being imported from off the island.

Assuming that Hatteras Island businesses must import a majority—say 75 percent—of all inputs from off-island, the multipliers would be less than those utilized in the assessment of the impact of no paved road access to Hatteras Island with the Pamlico Sound Bridge Corridor above. The multiplier, in this case, is estimated to equal 1.33.

In a very simple multiplier model, the value of the multiplier depends on the import or "leakage ratio", as follows: 1/1-(1-m) = multiplier, where m = the import leakage ratio. Assuming m = 0.75, the multiplier is calculated as 1.33. Overall secondary impact losses would be greater for the Outer Banks region and Dare County as a whole, as the multiplier is higher for the region than it is just for Hatteras Island, where import leakage is greater.

Using this multiplier, total economic losses on Hatteras Island, including direct and secondary impacts are shown in Table 4-8.

Table 4-8. Breach Direct and Secondary Economic Impact by Season

	Peak Season (millions, 2004 dollars)			Off-Peak Season (millions, 2004 dollars)			Mid-Season (millions, 2004 dollars)		
	Direct	Secon-dary	Total	Direct	Secon-dary	Total	Direct	Secon-dary	Total
1 month breach (average)	$36.68	$12.23	$48.91	$1.42	$0.47	$1.89	$11.57	$3.86	$15.43
3 month breach	$110.04	$36.69	$146.73	$4.26	$1.41	$5.67	$34.71	$11.58	$46.29

As seen in Table 4-8, the extent of the impact is highly variable, depending on the scenario considered. For example, a three month breach occurring at the height of the peak season could result in tourism-related economic losses on Hatteras Island of about $147 million. By contrast, a three month breach occurring during the off-peak season would entail relatively small tourism-related losses of around $6 million. The greatest potential impact would be a six-month breach occurring over the peak and mid-season time periods, which would result in a combined impact of $193.02 million ($146.73 plus $46.29).

Job Loss

Job losses were not estimated by breach scenario, because it is unclear whether and to what extent local seasonal employees would not be hired or permanent employees laid off as a result of the substantial but temporary reductions in activity. The likelihood is that temporary or seasonal employees would lose their jobs for breaches exceeding one month during the peak season; as discussed in Section 4.6.7, the minimum time to close a breach at the southern end of the Refuge would be three months.

A very rough estimate of the peak seasonal employment loss in the event of a breach over the full three months of the peak season is about 30,000 person-months (equivalent of 1 person working 30,000 months), assuming labor receives one third of the proceeds from retail sales in the form of wages, and that the average wage is $5,000 over a three month period.

Fiscal Impacts

Based on the losses estimated above, fiscal impacts for Dare County and North Carolina are estimated in Table 4-9. The greatest potential impact would be a six-month breach occurring over the peak and mid-season time periods, which would result in a combined impact of $21.13 million ($13.40 plus $3.34 plus $4.06 plus $0.33).

Table 4-9. Breach Fiscal Economic Impact by Season

	NC Sales Tax	NC Income Tax[1]	TOTAL STATE	Dare County Occupancy Tax (all occupancy taxes combined)	Dare County Food and Beverage Sales (millions)	TOTAL DARE COUNTY
Peak Season						
• 1 month breach	$3.60	$0.80	$4.40	$1.00	$0.05	$1.05
• 3 month breach	$10.90	$2.50	$13.40	$3.20	$0.14	$3.34
Mid-Season						
• 1 month breach	$1.10	$0.25	$1.35	$0.10	$0.01	$0.11
• 3 month breach	$3.30	$0.76	$4.06	$0.30	$0.03	$0.33
Off-Peak Season						
• 1 month breach	$0.10	$0.03	$0.13	$0.05	$0.01	$0.06
• 3 month breach	$0.40	$0.09	$0.49	$0.20	$0.02	$0.22

[1] Assumes a blended 6.5 percent state income tax rate. Also assumes that one-third of final retail sales are distributed as wages to employees.

Other Impacts

Other impacts could include the economic costs of time and inconvenience associated with the breach, for both passengers and goods. No analysis has been performed to assess the travel impacts of a breach for either category, but these effects would likely be substantial.

Frequency of Impacts

While the impacts are found to be substantial in any given year for peak season breach scenarios, the low probability of such a breach occurring in any given year greatly reduces the potential "life cycle" effect. As discussed in Section 3.6.3.4, the expert panel that was asked to assess the breach issue concluded that the storm event needed to create a breach likely would only occur once through 2060.

The size of the breach impact, particularly if the breach were to occur in the peak season, also makes it highly desirable to develop additional data that would help facilitate closing a breach. As discussed in Section 4.6.7, three months was considered the minimum time to close a breach with advance data gathering. Without advance data gathering, the time to close a breach would likely double to six months.

A breach, and its associated costs, would not be of concern with the Pamlico Sound Bridge Corridor, because the Refuge would be bypassed by the Pamlico Sound bridge. Except for accounting for the potential of such a breach in bridge location and foundation design, a breach and its economic impact also would not be a concern with the Parallel Bridge Corridor Alternatives, except for the two involving nourishment. The Rodanthe area bridges associated with all of Parallel Bridge Corridor alternatives (except those involving nourishment) would span the breach location. In the case of the Phased Approach/Rodanthe Bridge Alternative (Preferred), the breach location would be spanned in Phase II. The nourishment program associated with the Nourishment Alternative and the Phased Approach/Rodanthe Nourishment Alternative would reduce the risk of a breach occurring, but it would remain a possibility.

Other potential breach locations exist in the Refuge, as discussed in Section 3.6.3.4. The potential for a breach to occur at these locations between now and 2060 is considered minimal by expert panel members, with the potential being somewhat greater south of the Refuge's ponds at the location of the former New Inlet.

4.1.6 Community Services

The replacement bridge corridor alternatives would not substantially affect community services. The details of the potential effects of the replacement bridge corridor alternatives on emergency medical services, police and fire services, schools, the Rodanthe-Waves-Salvo Community Center, water and sewer services, solid waste disposal, telephone service, cable service, electric power service, and the emergency ferry dock are discussed in the following sections. The No-Action Alternative would have adverse impacts on emergency medical services, fire and police protection, schools, solid waste disposal, telephone services, and power.

4.1.6.1 Emergency Medical Services

With the replacement bridge corridor alternatives, ground transportation by ambulance would continue to use the bridge to reach the hospitals in Kitty Hawk, North Carolina; Norfolk, Virginia; Chesapeake, Virginia; and Elizabeth City, North Carolina. Replacing Bonner Bridge with a 17.5-mile (28.2-kilometer) long structure in the Pamlico Sound Bridge Corridor would

increase emergency vehicle travel distance for the ground transport of critically ill or injured persons and others requiring immediate aid across Oregon Inlet by approximately 2 miles (3.2 kilometers). The distance from Rodanthe to Bodie Island is approximately 2 miles (3.2 kilometers) longer with the Pamlico Sound Bridge Corridor than on the existing road. With a design speed of 60 miles per hour (mph) (96 kilometers per hour [kph]) for the Pamlico Sound Bridge Corridor, this could result in an increase in travel time of approximately two minutes. With the Parallel Bridge Corridor there would be no noticeable change in travel distance or time for emergency vehicles as compared to existing conditions.

Helicopters used to evacuate seriously injured accident victims would be able to land on the 40-foot-wide (12.2-meter) clear roadway width associated with the proposed bridges for all of the replacement bridge corridor alternatives. (Personal communication, January 6, 2004, Larry Mimms, Dare County EMS.) In addition, the 40-foot (12.2-meter) clear roadway width of these bridges would provide adequate space for other emergency vehicles to turn around and return to their station after responding to an emergency on the proposed bridge. (Personal communication, January 6, 2004, John Jones, Dare County EMS.)

With the No-Action Alternative, the ground transportation time required to transport critically ill or injured persons, and others requiring immediate aid, across Oregon Inlet would be increased by at least 80 minutes (the amount of time required for ferry service across Oregon Inlet) when the ferry is operating. This additional time to cross Oregon Inlet would increase the travel time to the Nags Head hospital nearly 90 percent. The substantially longer transport time would put the patient at greater risk of permanent disability or death from injury or illness. The lack of road access and the lack of ferry service late at night would increase the demand for emergency medical transportation by the county's helicopter.

4.1.6.2 Police and Fire Service

Construction of a replacement bridge within the Pamlico Sound Bridge Corridor would require emergency services (police and fire) supplied off-island from the north to travel approximately 2 miles (3.2 kilometers) farther to get from the bridge terminus on Bodie Island to the terminus in Rodanthe than what is needed on existing NC 12. The 40-foot (12.2-meter) clear roadway width of bridges associated with all of the replacement bridge corridor alternatives would provide adequate space for fire trucks to turn around and return to the fire station after responding to an emergency on the proposed bridge. (Personal communication, December 17, 2003, Ryan Lehman, Nags Head Fire Department.) With the Parallel Bridge Corridor there would be no noticeable change in travel distance or time for these emergency vehicles as compared to existing conditions.

The No-Action Alternative would lessen the flexibility of the fire and police service on Hatteras Island to obtain timely assistance from other fire departments elsewhere in the county or in adjoining counties during large-scale emergencies. The removal of roadway access between Bodie and Hatteras islands would disrupt the current patrol routes of the NPS and could eliminate coverage of Hatteras Island by the North Carolina Highway Patrol because of the decreased access across Oregon Inlet.

4.1.6.3 Schools

The school-aged population of Hatteras Island is served by school facilities on the island. The No-Action Alternative would curtail or increase travel time to extracurricular activities, including sporting events that involve off-island travel. The replacement bridge corridor alternatives would have no impact on Hatteras Island schools.

4.1.6.4 Rodanthe-Waves-Salvo Community Center

The Pamlico Sound Bridge Corridor's terminus in Rodanthe is north of SR 1492 (Myrna Peters Road), so the Pamlico Sound Bridge Corridor would not affect the Rodanthe-Waves-Salvo Community Center. The Rodanthe area bridge's southern approach road (associated with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives), however, would be in the same location as Myrna Peters Road. An alternate access to NC 12 would be provided immediately to the south of the community center.

For the Phased Approach alternatives (including the Preferred Alternative) , access would be altered at the north end of Rodanthe where two one-way frontage roads would be provided to maintain access to homes and businesses in the area where NC 12 is placed on a bridge. The Rodanthe-Waves-Salvo Community Center is in the area affected by the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) only. No other community facilities are along the portion of NC 12 that would be placed on a bridge. The one-way frontage roads, and limited number of crossovers between them, would create a slightly more circuitous route for emergency vehicles. Depending on the location of the home or business that they are trying to reach in relationship to the crossovers, they would likely have to go beyond the intended destination to make a U-turn either before or after making their stop. This effect would be least with the Phased Approach/Rodanthe Nourishment Alternative, which includes a shorter bridge in Rodanthe. With the Phased Approach/Rodanthe Bridge Alternative (Preferred), users of the Rodanthe-Waves-Salvo Community Center also would travel a more circuitous route.

4.1.6.5 Water

The replacement bridge corridor alternatives would not affect water service on Hatteras Island. There are separate water sources on Bodie Island, in the Refuge, and in Rodanthe. Existing water lines west of NC 12 in Rodanthe are for local distribution only, and alteration of these lines during construction of the bridge approach roads in Rodanthe would not affect overall service. (Personal communication, July 24, 2003, T.J. Ketterman, Dare County Water, Kill Devil Hills, NC.) The NCDOT would coordinate any construction activities with Dare County to minimize disruption of local service. The No-Action Alternative would have no impact on water service.

4.1.6.6 Sewer Service

The replacement bridge corridor alternatives would not affect sewer service, because there are no sewers in the project area.

4.1.6.7 Solid Waste Disposal

The replacement bridge corridor alternatives would not affect solid waste disposal. The No-Action Alternative would create a situation similar to that experienced when Bonner Bridge was damaged in October of 1990 and closed temporarily. The daily waste collections would have to be removed from the island via ferry for transport to the mainland landfill. Transport by ferry would double the daily operation time, thereby increasing operating costs. The time increase could be reduced by giving sanitation vehicles priority on the ferries or establishing a transfer station on Hatteras Island.

4.1.6.8 Telephone Service

The replacement bridge corridor alternatives would have no effect on telephone service provided to Hatteras Island. New telephone cables would be placed on or adjacent to the proposed replacement bridge with the Pamlico Sound Bridge Corridor and the bridge across Oregon Inlet

with the Parallel Bridge Corridor, replacing those now on Bonner Bridge. Disruption of service, as it is switched from the existing lines to the replacement lines, would be minimal. It is the preference of Sprint Communications (the current service provider) that service lines be attached to a replacement bridge over Oregon Inlet or Pamlico Sound through the use of pre-fabricated inserts installed during construction. This method would help reduce costs, provide access for maintenance, and reduce construction scheduling conflicts that could delay the demolition and removal (which would occur under a separate contract) of Bonner Bridge.

Costs associated with relocating telephone cables currently on Bonner Bridge would be greatest with the Pamlico Sound Bridge Corridor Alternatives at approximately $262,500 (2006 dollars) for 17.5 miles (28.2 kilometers) of relocation, and least on the Parallel Bridge Corridor alternatives (including the Preferred Alternative) at $54,000 for 2.7 miles (4.4 kilometers) of relocation. With most of the Parallel Bridge Corridor Alternatives, the telephone company would need to relocate its telephone lines on Hatteras Island in the project area periodically as the shoreline erodes. Through 2060, NCDOT estimates the following telephone line relocation costs along NC 12 in 2006 dollars:

- Nourishment Alternative: $0.0 million
- Road North/Bridge South: $0.8 million
- All other Parallel Bridge Corridor alternatives (including the Preferred Alternative): $1.5 million

The No-Action Alternative would require the development of an alternative system for providing telephone services to Hatteras Island, such as placement of submarine cables under Oregon Inlet.

4.1.6.9 Cable Service

The replacement bridge corridor alternatives would provide a reasonable means for Charter Communications to provide improved cable services to Hatteras Island. A replacement bridge would provide the opportunity for cables to be attached to the structure. Like Sprint Communications, Charter Communications would like to utilize pre-installed inserts attached to the bridge.

The No-Action Alternative would eliminate the potential for improving cable services on Hatteras Island. Charter Communications indicated that it would not be feasible to develop an independent conveyance of cable lines to the Island. (Personal communication, October 3, 2003, George Weaver, Charter Communications, Nags Head, NC.) The No-Action Alternative would have no impact to the existing services since customers are supplied cable service via satellite.

4.1.6.10 Electric Power

The replacement bridge corridor alternatives would have no effect on the availability of electric service to Hatteras Island because new transmission lines would be built. Disruption of service as it is switched from the existing lines to the replacement lines would be minimal. Design of aerial lines would have to take into account the potential need for an emergency helicopter to land on the bridge.

Costs associated with relocating electrical lines currently on Bonner Bridge would be greatest with the Pamlico Sound Bridge Corridor Alternatives at approximately $53.6 million (2007 Cape Hatteras Electrical Cooperative estimate).

The impact of absorbing a project of $53.6 million would be enormous according to the cooperative. The total plant investment of the cooperative in facilities as of October 2005 was $34.6 million. This option almost triples the present plant investment of the cooperative. The impact of increasing plant investment by a $53.6 million project would require an increase in retail electric rates by approximately 42 percent. The cooperative already has the highest utility plant investment per meter served and retail rates among the highest of electric cooperatives in North Carolina.

Relocation of electric lines onto the new Oregon Inlet bridge with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would cost as much as $12 million (2007 Cape Hatteras Electrical Cooperative estimate). While this cost greatly exceeds typical cooperative electric system projects, the cooperative has indicated that it long expected the requirement. With most of the Parallel Bridge Corridor Alternatives, the cooperative would need to relocate its electrical lines on Hatteras Island periodically in the project area as the shoreline erodes. Through 2060, the NCDOT estimated the following electrical line relocation costs in 2006 dollars:

- Nourishment Alternative: $0.0 million
- Road North/Bridge South Alternative: $2.0 million
- All other Parallel Bridge Corridor alternatives (including the Preferred Alternative): $3.8 million

The No-Action Alternative would disrupt power service to Hatteras Island because Bonner Bridge would be demolished at the end of its service life and transmission lines are carried on the bridge. A representative of the electric cooperative indicated that there are two possibilities for the continuation of power service to Hatteras Island under the No-Action Alternative. (Personal communication, October 23, 2003, Jim Kinghorn, Cape Hatteras Electric Membership Association, Buxton, NC.) The two possibilities are:

1. Construction of large, independent towers to transmit the high-voltage aerial lines to the island; and

2. Construction of steam generators on Hatteras Island.

Each alternative would have economic and environmental consequences. Construction of towers to convey aerial lines would increase cost and risk for the electric cooperative. Line maintenance would be conducted from boats in Pamlico Sound. Construction and maintenance of supporting structures would face many of the same challenges as construction of foundations for a new Oregon Inlet bridge. The construction of primary-source steam generators on Hatteras Island would necessitate development of an oil terminal, and the fuel cost of supplying and running the generators would be high. The high construction costs and environmental impact potential of transmission towers or generators would involve a lengthy and difficult permitting process with no guarantee of success.

4.1.6.11 Emergency Ferry Dock

The Pamlico Sound Bridge Corridor is north of the NCDOT's emergency ferry dock in Rodanthe and the channel used by ferries to reach the dock. The Pamlico Sound Bridge Corridor's terminus in Rodanthe is north of the road connecting the dock to NC 12 and would not affect the dock or its operations. The Rodanthe area bridge's southern approach road (associated with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives) would be in

the same location as the current access road to the emergency ferry dock, and a new access road to the emergency ferry dock would be built with these alternatives. An alternate access to NC 12 would be provided immediately to the south of the Rodanthe-Waves-Salvo Community Center. Access to the emergency ferry dock would not change with the Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative. With the Phased Approach/Rodanthe Bridge Alternative (Preferred), users of the ferry dock, like those of the Rodanthe-Waves-Salvo Community Center, would travel a more circuitous route to get to and from the dock via the frontage roads that would parallel the new NC 12 bridge passing through Rodanthe and bypass the ferry terminal access road.

4.1.7 Oregon Inlet Users

The replacement bridge corridor alternatives would make navigation through Oregon Inlet safer by providing wider horizontal clearances than exists today between piers. The No-Action Alternative would eliminate any constraints that Bonner Bridge now places on Oregon Inlet users.

A bridge in either the Pamlico Sound Bridge Corridor or the Parallel Bridge Corridor would have a minimum navigation span horizontal clearance of 200 feet (60.1 meters). The vertical clearance at the navigation spans would be 75 feet (22.9 meters) above mean high water. With the Pamlico Sound Bridge Corridor, the navigation zone (area with spans of the navigation span height and width) would be 1,600 to 2,000 feet (488 to 610 meters) long. With the Parallel Bridge Corridor, the navigation zone across Oregon Inlet would include a series of navigation spans across the inlet for up to approximately 5,000 feet (1,524 meters), except with the two Phased Approach alternatives (including the Preferred Alternative) where the navigation zone would be 3,300 feet (1,006 meters). These dimensions would be adequate to provide for the navigation needs of current and anticipated future inlet users. The navigation zone with the Phased Approach alternatives (including the Preferred Alternative) would not affect channel use. The typical size of vessels using Oregon Inlet in the future is not expected to exceed that of the largest commercial fishing boats using the inlet today. The maximum size of vessels utilizing the inlet is not expected to increase, primarily because of the shallow authorized depth.

The replacement bridge corridor alternatives would make navigation through Oregon Inlet safer by providing wider horizontal clearances than exists today between piers. The potential threat of vessel collisions with the replacement bridge corridor alternatives would be less than with Bonner Bridge because of the proposed increase in horizontal clearance. This would allow fishing vessels to lower their outriggers as they pass beneath the bridge, and it would provide more room for error than exists now when a vessel passes under the bridge during storm conditions. The replacement bridge also would be designed to withstand the impact of dredging vessels.

Charter fishing boats operating out of the Seashore's Oregon Inlet Marina and Fishing Center use an unmarked natural channel known as Bridge to Old House Channel (or known more commonly as "the crack") to reach the navigation span of Bonner Bridge, rather than the Oregon Inlet Channel/Old House Channel maintained by the USACE. (Figure 3-7 shows the location of channels in the Oregon Inlet area.) On a peak day, approximately 130 charter vessels use "the crack." Use of "the crack" shortens the distance traveled by vessels operating between the fishing center and Bonner Bridge's navigation span from approximately 5 miles (8 kilometers) to about 2.5 miles (4.0 kilometers). As illustrated in Figure 3-7, a bridge in either the Pamlico Sound Bridge Corridor or the Parallel Bridge Corridor would cross "the crack" as the bridge moves southwest into Pamlico Sound. Since charter fishing boats require as much as 30 feet (9 meters) of clearance, a bridge in these corridors would block the channel's use by these vessels and

increase the time it takes for these vessels to move from the fishing center to the ocean, since they would be required to use the Oregon Inlet Channel/Old House Channel maintained by the USACE. The travel time to the ocean from the fishing center would be approximately 30 minutes longer via the Oregon Inlet Channel/Old House Channel than via "the crack." Crossing "the crack" by a bridge cannot be avoided with either replacement bridge corridor, since "the crack" runs adjacent and parallel to Bonner Bridge for part of its length.

Under the No-Action Alternative, removal of Bonner Bridge would eliminate any constraints that Bonner Bridge now places on Oregon Inlet users.

4.1.8 Underground Storage Tanks and Hazardous Waste

The Pamlico Sound Bridge Corridor with the Curved Rodanthe Terminus would affect a portion of the Liberty service station, but none of its current underground storage tanks (USTs) are within the area directly affected. Both Rodanthe terminus options for the Pamlico Sound Bridge Corridor would affect the Rodanthe junkyard in the project area, although junked cars were removed from a part of the area between 2003 and 2004. The preliminary site assessment conducted for these properties for the Pamlico Sound Bridge Corridor found minor concentrations of Diesel Range Organics (diesel fuel and associated compounds) in two soil samples (Catlin Engineers and Scientists, December 2003). The assessment concluded that these minor concentrations should not require further action for soils left in place. However, if soils were excavated in these areas during roadway construction, they would be handled as petroleum impacted waste. Contaminated soils would be removed and disposed as per state and federal requirements for transportation, treatment, storage, and disposal of such soils. Extra costs associated with handling contaminated soils would be taken into account when negotiating the purchase price of proposed right-of-way containing such soils.

The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would displace the gas pumps closest to NC 12 at the Liberty service station, as well as the gas pumps at the North Beach Beach Mart and Campground convenience store in Rodanthe. Low monetary and scheduling impacts are anticipated from these sites. A full site investigation would have to be conducted to determine whether the USTs are affected and whether they have leaked into surrounding soils. If contaminated soils are present, they would be removed and disposed of as per state and federal requirements as noted in the previous paragraph.

No contaminated soils or USTs would be disturbed with the No-Action Alternative.

A replacement bridge within the Pamlico Sound Bridge Corridor would substantially increase the distance (17.5 miles [28.2 kilometers] versus the current 2.4 miles [3.9 kilometers]) that ground transport of hazardous materials between Bodie and Hatteras islands would be over water. The Rodanthe area bridge (associated with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives) would include 1.8 miles (2.9 kilometers) over water in addition to the Oregon Inlet bridge. The length of the Oregon Inlet bridge in the Parallel Bridge Corridor would be similar in length to Bonner Bridge, so there would be no additional risk of spills associated with bridge length in this portion of the Parallel Bridge Corridor. In the event of hazardous waste or oil spills, emergency response procedures established under the Dare County 2001 Emergency Operations Plan would be followed. In addition, the requirements would apply to spills of oil and those chemicals listed in the Federal Clean Water Act, whether on the ground or in water bodies, including off-shore spills.

4.1.9 Farmland

There are no important farmland soils within the replacement bridge corridor alternatives.

4.2 Environmental Justice

Executive Orders 12898 and 13045 require federal agencies to identify and address, as appropriate, the potential for disproportionately adverse human health or environmental effects of federal programs, policies, and activities on minority and low-income populations. These requirements were met by analyzing environmental justice data in accordance with regulatory guidance from the Council on Environmental Quality (CEQ) (CEQ, 1997), US Environmental Protection Agency (USEPA) (USEPA, 1998), and US Department of Transportation (USDOT) guidelines for assessing environmental justice impacts (USDOT, 1997).

Three criteria must be met for impacts to minority and low-income communities or children to be considered significant: 1) there must be one or more populations within the region of comparison (ROC); 2) there must be adverse (or substantial) impacts from the proposed action; and 3) the environmental justice populations within the ROC must bear a disproportionate burden of those adverse impacts. If any of these criteria are not met, then impacts with respect to environmental justice or protection of children would not be substantial. The analysis contained in this Final Environmental Impact Statement (FEIS) is consistent with Executive Orders 12898 and 13045.

As documented in Section 3.2, there are no concentrations of any minority group or low-income populations within the project area. Thus, there is no evidence that the replacement bridge corridor alternatives or the No-Action Alternative would disproportionately affect low-income or minority households.

4.3 Visual Impacts

The following sections discuss the nature of the visual impacts for the Pamlico Sound Bridge Corridor and Parallel Bridge Corridor alternatives (including the Preferred Alternative) from the perspectives of Rodanthe, the Refuge, and Oregon Inlet, all of which are consistent parts of the Seashore in the project area.

4.3.1 Rodanthe

With both bridge corridors, a new bridge would be introduced to Rodanthe views, although the views affected differ between the alternatives. The No-Action Alternative would not affect views at Rodanthe.

4.3.1.1 Pamlico Sound Bridge Corridor

Views of the Pamlico Sound from homes along the sound's shoreline (and second-story homes farther away from the Sound) in Rodanthe are panoramic and unobstructed. A bridge in the Pamlico Sound Bridge Corridor would result in substantial changes to these views. The intactness and unity of the landscape would be reduced by the introduction of project features. The location of the Pamlico Sound Bridge Corridor minimizes impacts to views by maintaining a predominantly straight and perpendicular final approach to land that extends for approximately 3 miles (4.8 kilometers) of the southernmost portion of the structure. With this location, the

proposed bridge would not obscure the full panorama of the views of Pamlico Sound from homes along the shoreline.

The bridge generally would obscure approximately one-third of the panorama as the bridge moves west into the Sound. For the rest of the panorama, the bridge would appear as a thin line on the horizon in the day. At night, the lights of motor vehicles would be visible, off in the distance for much of the panorama and closer as the proposed bridge approaches the shore. Roadway lighting is not planned for the proposed bridge.

Visual impacts would be greatest for homes closest to the proposed Pamlico Sound bridge. With the Curved Rodanthe Terminus Option, more than half of the panoramic view of the Sound would be obscured at the home immediately north of the terminus option.

The Rodanthe approach road within the Pamlico Sound Bridge Corridor would change landforms and vegetation, as well as displace several existing buildings, and part of an automobile junkyard. None of these features contribute to views of high quality. Thus, their replacement by the Pamlico Sound bridge and its approach road would not adversely affect the area's visual quality. The Pamlico Sound bridge and its Rodanthe approach road would be visible from the watchtower that is a part of the historic Chicamacomico Life Saving Station building. The current viewshed is occupied by modern commercial and residential development and the junkyard. Therefore, the change would not affect the integrity of this view.

4.3.1.2 Parallel Bridge Corridor with NC 12 Maintenance

The Parallel Bridge Corridor with Nourishment would not affect the Rodanthe area. A bridge would be built west of Rodanthe with the Road North/Bridge South and the All Bridge alternatives. Again, views of the Pamlico Sound from homes along the shoreline (and second-story homes further away from the Sound) in Rodanthe are panoramic and unobstructed. A bridge in this corridor would result in substantial changes to these views. The Rodanthe area bridge would be closer (1,400 to 1,700 feet [427 to 518 meters]) to the shore over its full length than the Pamlico Sound Bridge Corridor bridge, which would be roughly perpendicular to the shore. The intactness and unity of the view would be split by the line of the Rodanthe area bridge across the full 180 degrees of the view. At night, the lights of motor vehicles would be visible. Roadway lighting is not planned for the proposed bridge.

The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would substantially affect the Rodanthe area, introducing an elevated roadway into the community for a distance of 1.1 miles (1.8 kilometers) beginning at the Refuge boundary. A bridge would be built with a one-lane/one-way frontage road on either side of the bridge at-grade to maintain access to adjoining properties. On either side of NC 12, pavement would be approximately 34.5 feet (10.5 meters) closer to adjoining homes and businesses. The bridge would be at its full height of approximately 33.5 feet (10.2 meters) above mean sea level (approximately 30 feet [9.1 meters] above ground) as it enters Rodanthe from the north (see Figure 2-24). The bridge would remain at its full height for 0.8 miles (1.3 kilometers) and then begin to descend to ground level. The final 400 feet (122.0 meters) of the elevated roadway would be on fill contained by retaining walls.

Within the area of effect described for the Phased Approach/Rodanthe Bridge Alternative (Preferred), approximately 90 residential and/or business structures are along NC 12 and would be within 100 feet of the new bridge. The elevated structure would impede the viewshed of the primary viewers looking east towards the Atlantic Ocean and ocean-side viewers looking west.

Views could be blocked by the elevated structure as high as the third or fourth story. At an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (approximately 30 feet [9.1 meters] above ground), the bridge would be a dominating presence at ground level, particularly for those 90 homes and businesses close to the bridge (see Figure 2-24). The combination of the bridge's height, length, structural characteristics, and materials would present a structure not in keeping with the existing character of the area.

The bridge with the Phased Approach/Rodanthe Bridge Alternative (Preferred) would be a sizable man-made addition to views from homes in Rodanthe into the Refuge at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (approximately 30 feet [9.1 meters] above ground). It would present a stark contrast with the natural character of the Refuge and would be the tallest feature in the Refuge, since existing dunes are generally no more than 20 feet (6.1 meters) high. The bridge's presence in views would be most prominent near the Refuge border and would diminish as the bridge continues north away from Rodanthe.

The potential for beach erosion is severe in the Rodanthe area. By 2060, as a result of the beach eroding under the bridge, the majority of the bridge would be in the ocean (as far as 930 feet [283.5 meters] offshore) and would be a presence within ocean views except for at its southern end (where the bridge will approach its terminus at NC 12 right-of-way that will not erode away but will remain in 2060). Most of the homes with views of the Phased Approach/Rodanthe Bridge Alternative (Preferred) bridge would be lost to beach erosion.

Views of the Pamlico Sound from homes along the sound shoreline in Rodanthe are panoramic and unobstructed. A bridge with the Phased Approach/Rodanthe Bridge Alternative (Preferred) would not affect views of the Sound, but would obscure the view for soundside homes with a view of the Atlantic Ocean.

The Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative would affect the Rodanthe area, introducing an elevated roadway into the community for a distance of 0.3 mile (0.5 kilometer). Within this distance, about 30 residential or business structures along the existing roadway would be within 100 feet of the new bridge. Visual impacts would be the same as described for the Phased Approach/Rodanthe Bridge Alternative (Preferred) but less severe overall because of the shorter bridge length in Rodanthe.

4.3.2 Pea Island National Wildlife Refuge

The Pamlico Sound Bridge Corridor is not within the Refuge and is far enough from the Refuge to have no adverse visual effect.

In the Parallel Bridge Corridor, the Nourishment Alternative would be within the same right of way as existing NC 12. The visual effect of this alternative is minimal, as beach nourishment and dune placement would be the only action. Views of the ocean from the road would be obscured by new dunes, but dunes are already an almost constant presence along NC 12 within the Refuge. New dunes would not represent a substantial visual change.

The Parallel Bridge Corridor with Road North/Bridge South Alternative would include the start of the Rodanthe area bridge, whose visual impacts are described in Section 4.3.1.2, and the relocation of NC 12 as a road at the same elevation as existing NC 12. The horizontal shift of the road west would change the appearance of the surrounding terrain, changing wetland to road and narrowing the ponds as much as 700 feet (213.4 meters). From the perspective of its impact on the historic landscape of the naturalized setting in the Refuge, as enhanced by the Civilian

Conservation Corps in the 1930s, this alternative was found to have an Adverse Effect (see Section 4.4.1.2) under the requirements of Section 106 of the Historic Preservation Act of 1966. From the perspective of general visual change for visitors to the Refuge, no long distance views would be blocked or altered, and the vegetation in the immediate area of existing NC 12 and the new road would be restored. Thus, the long-term visual impact of this alternative would be low and no greater than the natural changes in the current landscape resulting from beach erosion and ocean overwash.

The Parallel Bridge Corridor with All Bridge Alternative would represent a sizeable intrusion into the landscape of the Refuge. The All Bridge Alternative would introduce a sizeable new linear man-made feature for approximately 7.5 miles (12.1 kilometers) through the Refuge. The bridge through the Refuge with this alternative would be built as much as 900 feet (274.4 meters) west of the existing road, following a straighter alignment than the Road North/Bridge South Alternative. The bridge would be approximately 28 feet (8.5 meters) above the existing ground line, allowing for the bottom of the superstructure (bridge spans) to be a minimum of 10 feet (3 meters) above mean high water. This height is similar to the height of the tallest of the dunes that line much of the shoreline in the Refuge. Bridge foundations probably would be built every 100 feet (30.5 meters). The bridge structure would pass above the wildlife trails on top of the dikes associated with the northernmost pond and over the ponds. The bridge would present a contrast with the natural character of the Refuge. The bridge would dominate views from the dunes lining the beach and, as the dunes disappear over time, it would also dominate views from the beach. It would also dominate views from the wildlife trails along the Refuge's ponds, interrupting the undeveloped and protected character of the Refuge that makes it rare along the eastern US seaboard in terms of views and a setting for recreation activities.

Like the All Bridge Alternative, the Phased Approach alternatives (including the Preferred Alternative) would represent a sizeable intrusion into the landscape of the Refuge. The Phased Approach alternatives (including the Preferred Alternative) would introduce a sizeable new linear man-made feature for approximately 10 miles (16.1 kilometers) through the Refuge, intrude approximately 700-feet into the existing dikes and ponds, and alter the naturalized setting enhanced by the Civilian Conservation Corps in the 1930s. NC 12 through most of the Refuge would be elevated to a bridge within the existing easement. The bridge would be at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (approximately 30 feet [9.1 meters] above ground), allowing for the bottom of the superstructure to be a minimum of 25 feet (7.6 meters) above mean high water (see Figure 2-24). This is 15 feet (4.6 meters) higher than the height assumed for the All Bridge Alternative.

Like the All Bridge Alternative, the bridge would present a contrast with the natural character of the Refuge. The bridge would dominate views from the dunes lining the beach and, as the dunes disappear over time, it also would dominate views of the beach and ultimately the ocean. It would not be characteristic of the undeveloped and protected character of the Refuge that makes it rare along the eastern US seaboard in terms of views and a setting for recreation activities.

With the No-Action Alternative, views in the Refuge would not be changed except by natural shoreline erosion.

4.3.3 Oregon Inlet

Three viewpoints occur in the Oregon Inlet area: the northern end of Hatteras Island, the spit and the southern end of Bodie Island, and the Oregon Inlet Marina and Oregon Inlet Campground

area. The Parallel Bridge Corridor would be present in all three of these viewpoints. The Pamlico Sound Bridge Corridor would be a notable visual presence only in the Oregon Inlet Marina and Oregon Inlet Campground area.

With the No-Action Alternative, Bonner Bridge would be removed and not replaced. Thus, Bonner Bridge would no longer be in view at the three viewpoints. A clearer view of Oregon Inlet and Pamlico Sound would be introduced from viewpoints on the south end of Bodie Island and the north end of Hatteras Island with the No-Action Alternative.

4.3.3.1 Northern End of Hatteras Island

At its Hatteras Island terminus, the Oregon Inlet bridge associated with the Parallel Bridge Corridor alternatives would be taller than Bonner Bridge, which enters Hatteras Island at an elevation of approximately 15 feet (4.6 meters). The new Oregon Inlet bridge would include navigation spans over Oregon Inlet, and it would eventually reach Hatteras Island at a higher elevation than the current bridge. The new bridge would enter Hatteras Island at an elevation of approximately 70 feet (21.3 meters) with the Nourishment Alternative. The elevation would be 57 feet (17.4 meters) with the Road North/Bridge South and All Bridge alternatives. With the Phased Approach alternatives (including the Preferred Alternative), the new bridge would enter Hatteras Island at an elevation of approximately 33.5 feet (10.2 meters) and would remain at that height in the vicinity of the historic (former) Oregon Inlet US Coast Guard Station and as the bridge continues south. The bridge and its roadway approach for the other Parallel Bridge Corridor alternatives would drop to the existing grade over the course of approximately 2,700 feet (823.1 meters). The Phased Approach alternatives' bridges would be a more dominant component of views from the (former) Oregon Inlet US Coast Guard Station and other viewpoints on the northern end of Hatteras Island than the existing bridge.

Thus, a new Oregon Inlet bridge would be a more dominant component of views from the (former) US Coast Guard Station and other viewpoints on the northern end of Hatteras Island.

In addition to the new bridge, the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) would include three additional visual features:

1. In the interval between the completion of Phase I (the bridge over Oregon Inlet) and the completion of Phase II (assumed to be about three years), drivers would enter and leave the bridge over Oregon Inlet via two ramps, and the bridge structure would end at its full height;

2. Four ramps ultimately would be built from the bridge to the ground to provide access to the (former) Oregon Inlet US Coast Guard Station and the existing parking lot in the area; and

3. The traffic maintenance bridge that would be built east of the new bridge in the existing easement could possibly be retained as a fishing pier.

A bridge within the Pamlico Sound Bridge Corridor would be farther (e.g., more than 1.5 miles [2.4 kilometers]) from the northern end of Hatteras Island than Bonner Bridge. Thus, the scale of a replacement bridge in the Pamlico Sound Bridge Corridor in relation to viewers at the (former) US Coast Guard Station and other viewers in this area would be far less than that of Bonner Bridge. A replacement bridge in the Pamlico Sound Bridge Corridor would be visible for a greater distance than Bonner Bridge given the proposed bridge's longer length and height. However, it would appear as a thin line on the horizon when visible because the proposed bridge would be several miles farther offshore.

4.3.3.2 Bodie Island Spit

A new Oregon Inlet bridge (in the Parallel Bridge Corridor) would not affect views from the Bodie Island spit. No substantial change would occur in the quality of resource components. The scale and dominance of the Oregon Inlet crossing would not be substantially changed. An Oregon Inlet crossing would continue to be the predominant visual element. The new Oregon Inlet bridge would be slightly farther away, and would present a less complex or cleaner appearance than Bonner Bridge. The Pamlico Sound Bridge Corridor bridge would be approximately 4,000 feet (1,220 meters) from the spit and not a notable visual feature. Bonner Bridge would be removed from spit views, so there would no longer be an Oregon Inlet bridge visible from the spit with the Pamlico Sound Bridge Corridor.

4.3.3.3 Oregon Inlet Marina and Oregon Inlet Campground Area

No substantial visual impact would result in the Oregon Inlet Marina and Oregon Inlet Campground area with a replacement bridge in the Pamlico Sound Bridge Corridor. The Pamlico Sound Bridge Corridor's disturbance to landforms and vegetation would be limited to the bridge approach on Bodie Island. Lands formerly used for the Bonner Bridge approach would be restored in a manner in keeping with the surrounding landforms and vegetation after Bonner Bridge is demolished. The Pamlico Sound Bridge Corridor would be slightly closer to the Oregon Inlet Marina than Bonner Bridge. Thus, the scale of the proposed bridge in relation to the marina would be somewhat greater than that of Bonner Bridge. The Pamlico Sound Bridge Corridor would be slightly farther from the Oregon Inlet Campground on Bodie Island. The visual impact in the area of the Oregon Inlet Marina and Oregon Inlet Campground would be the same with the Parallel Bridge Corridor as it currently is with Bonner Bridge.

4.4 Cultural Resources

This section describes the effects of the replacement bridge corridor alternatives on historic and archaeological resources, in accordance with Section 106 of the National Historic Preservation Act of 1966 (36 *Code of Federal Regulations* [CFR] Part 800).

4.4.1 Architectural and Landscape Resources

Figure 3-3 shows the Area of Potential Effects for the replacement bridge corridor alternatives. The historic resources within the Area of Potential Effects are:

- Pea Island National Wildlife Refuge (determined eligible);
- The (former) Oregon Inlet US Coast Guard Station building (National Register) at the northern end of Hatteras Island;
- Rodanthe Historic District (determined eligible) at the southern end of the project area; and
- The Chicamacomico Life Saving Station (National Register), which stands within the Rodanthe Historic District.

An Adverse Effect is defined in the regulations of the Advisory Council on Historic Preservation that implement Section 106 of the National Historic Preservation Act of 1966 (36 CFR Part 800.5(a)(1)) as:

> An Adverse Effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.

The regulations also give the following examples of adverse effects:

> (i) Physical destruction of or damage to all or part of the property;
>
> (ii) Alteration of a property, including restoration, rehabilitation, repair, maintenance, stabilization, hazardous material remediation, and provision of handicapped access, that is not consistent with the Secretary's standards for the treatment of historic properties (36 CFR Part 68) and applicable guidelines;
>
> (iii) Removal of the property from its historic location;
>
> (iv) Change of the character of the property's use or of physical features within the property's setting that contribute to its historic significance;
>
> (v) Introduction of visual, atmospheric or audible elements that diminish the integrity of the property's significant historic features;
>
> (vi) Neglect of a property which causes its deterioration, except where such neglect and deterioration are recognized qualities of a property of religious and cultural significance to an Indian tribe or Native Hawaiian organization; and
>
> (vii) Transfer, lease, or sale of property out of Federal ownership or control without adequate and legally enforceable restrictions or conditions to ensure long-term preservation of the property's historic significance.

The following sections present the Section 106 determination of effect for the three historic resources in the areas of potential effects (APE). These determinations of effect were made at meetings between representatives of the NCDOT, the Federal Highway Administration (FHWA), and the State Historic Preservation Officer (SHPO) on November 25, 2003 for the Pamlico Sound Bridge Corridor and June 28, 2005 and December 1, 2006 for the Parallel Bridge Corridor. The concurrence forms are included in Appendix B. Reasons for the eligibility of these resources are presented in Section 3.4.1.

4.4.1.1 Pamlico Sound Bridge Corridor

Pea Island National Wildlife Refuge

The Pamlico Sound Bridge Corridor is not within the Refuge and there will be no construction activities within the Refuge. Thus, a bridge in the Pamlico Sound Bridge Corridor would have No Effect on the Refuge.

(Former) Oregon Inlet US Coast Guard Station

A replacement bridge in the Pamlico Sound Bridge Corridor would not directly affect the (former) US Coast Guard Station. As indicated in the previous section, however, efforts required to maintain NC 12 are not consistent with the management goals of the Refuge. Thus, although the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge and this portion of the Seashore, the method of access could be something different than a paved road between Rodanthe and Oregon Inlet. The (former) US Coast Guard Station is at the northern end of Hatteras Island. Thus, a change in the access strategy could affect the accessibility of the (former) US Coast Guard Station and, therefore, its value for an alternative use on its current site. This change could cause continued neglect of the property.

The continued migration of Oregon Inlet threatened the southern terminus of Bonner Bridge and the north end of Hatteras Island in the late 1980s. Thus, the NCDOT built a terminal groin to protect the bridge. With the construction of the terminal groin, Hatteras Island migration to the south was halted. As such, the terminal groin also now protects the (former) US Coast Guard Station. The NCDOT has no current plans to remove the terminal groin on Hatteras Island after Bonner Bridge is demolished. The terminal groin is not needed in order to build and maintain a bridge in the Pamlico Sound Bridge Corridor, and neither is its removal. The performance of the terminal groin would not be affected by the construction of a bridge in the Pamlico Sound Bridge Corridor. The terminal groin could serve parties other than NCDOT and other immediate needs besides protecting Bonner Bridge. It is conceivable, however, that circumstances could change at some time in the future such that it could prove prudent to remove the terminal groin. In addition, the permit from the Refuge that allowed the construction of the terminal groin states that the purpose of the terminal groin is to "…protect the southern segment of the existing Herbert C. Bonner Bridge and its southern approach of North Carolina Highway 12." The permit also states that the NCDOT can use the lands and waters occupied by the terminal groin for as long as they "are used for the purpose granted." If the groin is removed, the north end of Hatteras Island would continue its movement south (see Section 3.6.3.5) and, unless relocated, the (former) US Coast Guard Station would be washed away.

Therefore, because of the potential loss of access and the potential removal of the terminal groin, a replacement bridge in the Pamlico Sound Bridge Corridor would have an Adverse Effect on this resource.

The Refuge and the Seashore plan to conduct an access study. The NCDOT would seek and accept an invitation to participate in the development of alternate access plans if a Pamlico Sound Bridge Corridor Alternative is selected for construction, and it would suggest that the SHPO be invited to participate. If the alternate access provided is found by the SHPO to contribute potentially to the further neglect of the (former) US Coast Guard Station, the NCDOT would help ensure this potential impact is adequately mitigated. Such mitigation would not include retaining NC 12 in the Refuge. If mitigation would include relocating the (former) US Coast Guard Station to a site north of Oregon Inlet, the NCDOT currently expects not to demolish Bonner Bridge until that relocation occurred or until a process for taking the building across Oregon Inlet on a barge is developed. However, given the current condition of Bonner Bridge, consideration would have to be given to whether the weight of the (former) US Coast Guard Station could be safely borne by Bonner Bridge before relocation across the bridge could take place.

If NCDOT is required to remove the groin following completion of the demolition and removal of Bonner Bridge, the NCDOT and representatives of the USFWS would assess the impacts of groin removal in a separate environmental study, as needed, prior to any final decision to remove the terminal groin. Such a study would assess impacts to the (former) US Coast Guard Station.

Chicamacomico Life Saving Station and Rodanthe Historic District

In the Rodanthe portion of the APE, the National Register-listed Chicamacomico Life Saving Station and several nearby houses form the National Register-eligible Rodanthe Historic District. The Pamlico Sound Bridge Corridor is outside of the boundaries of these resources.

The proposed bridge within the Pamlico Sound Bridge Corridor would be visible from the watchtower that is a part of the Life Saving Station building. However, the viewshed currently is occupied by modern commercial and residential development and an automobile junkyard (partially removed between 2003 and 2004). Thus, the integrity of the view has already been compromised.

At one house within the district, peak-hour noise levels in 2025 would approach or exceed the FHWA's Noise Abatement Criteria (NAC) with the Pamlico Sound Bridge Corridor. However, this noise level is associated more with the forecast growth in traffic than the implementation of a bridge within the Pamlico Sound Bridge Corridor. There would be no difference at the affected site between 2025 noise levels assuming Bonner Bridge remains in place and 2025 noise levels with the Pamlico Sound Bridge Corridor. In addition, 2025 noise levels with the Pamlico Sound Bridge Corridor would only be 2 dBA (A-weighted sound level in decibels) above existing conditions, an imperceptible difference.

Since the Pamlico Sound Bridge Corridor ends north of the eligible district, the proposed bridge would not affect traffic volumes that pass through the district on NC 12. Because of the lack of direct or substantial indirect affects on the district, there is no reason to believe that a bridge in the Pamlico Sound Bridge Corridor would lead to neglect of the properties within the district. The Chicamacomico Life Saving Station would not leave control of its owners.

Given these findings, the Pamlico Sound Bridge Corridor would have No Adverse Effect on the Chicamacomico Life Saving Station and the associated historic district.

4.4.1.2 Parallel Bridge Corridor Alternatives

Pea Island National Wildlife Refuge

With the Nourishment Alternative, the NC 12 roadway would remain within its existing easement, although two features would be introduced to the Refuge. The first would be a taller Oregon Inlet bridge southern terminus. Bonner Bridge currently enters Hatteras Island at an elevation of approximately 15 feet (4.6 meters). The new bridge would enter Hatteras Island at an elevation of approximately 70 feet (21.3 meters). The new bridge would have a navigation span that spans Oregon Inlet, thus it would reach Hatteras Island at a higher elevation than the current bridge. The bridge and its roadway approach would drop to the existing grade over the course of approximately 2,700 feet (823.1 meters). Second, several dunes approximately 10 feet (3 meters) high would be constructed in the area of the dikes and ponds created by the Civilian Conservation Corps (CCC) in the 1930s. Ten feet (3 meters) is the approximate height of the original dunes also built by the CCC. Two additional dunes approximately 20 feet (6.1 meters) high would be built at the south end of the Refuge. The dikes and ponds created by the CCC would remain in their current state, protected from further island erosion by the nourishment program. The Nourishment Alternative would have No Adverse Effect on the Refuge since the new dunes would be on the east side of NC 12, and the existing dikes and ponds would remain in place.

With the Road North/Bridge South Alternative, NC 12 would be moved west on a new roadway in association with the taller Oregon Inlet bridge described above. Three short, 10-foot (3-meter) high new dunes would be built as needed beginning in 2030. The road component would be built approximately 230 feet (70.1 meters) west of the 2060 high erosion shoreline, narrowing the width

of the ponds built by the CCC by as much as 700 feet (213.4 meters). This is the minimum relocation possible if NC 12 is to be maintained without additional relocations under high erosion conditions until 2060. The relocated road would be at the same elevation as the existing road. South of the ponds, NC 12 would veer west to be relocated on a bridge just west of the Refuge. The relocation would begin approximately 1.9 miles (3.1 kilometers) north of the southern boundary of the Refuge and approximately 3.8 miles (6.1 kilometers) south of the southernmost pond. The bridge would be approximately 28 feet (8.5 meters) above the surface of Pamlico Sound. The Road North/Bridge South Alternative would have an Adverse Effect on the Refuge, because the relocation of NC 12 would intrude into the existing dikes and ponds for approximately 3.5 miles (5.6 kilometers) (i.e., the entire length of the three ponds from north to south) at a distance of up to 700 feet (213 meters) to the west of existing NC 12. The Refuge was found to be eligible for the NRHP under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history (see Section 3.4.1.1). A letter dated September 17, 2003 from the North Carolina SHPO that affirms this finding is contained in Appendix A.

With the All Bridge Alternative, NC 12 would be moved west mostly on a bridge in association with the taller Oregon Inlet bridge described above. No dunes would be built. The bridge component would be built as much as 900 feet (274.4 meters) west of the existing road, following a straighter alignment than the road alternative. The bridge would be approximately 28 feet (8.5 meters) above the existing ground line, allowing for the bottom of the superstructure (bridge spans) to be a minimum of 10 feet (3 meters) above mean high water. This height is similar to the height of the tallest of the dunes that line much of the shoreline in the Refuge. Bridge foundations probably would be built every 100 feet (30.5 meters). The bridge structure would pass above the wildlife trails on top of the dikes associated with the northernmost pond and over the ponds. The All Bridge Alternative would introduce a sizable new linear visual feature for approximately 7.5 miles (12.1 kilometers) through the Refuge. The All Bridge Alternative would have an Adverse Effect on the Refuge because the elevation of NC 12 on a bridge would place NC 12 over the existing dikes and ponds. The Refuge was found to be eligible for the NRHP under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history (see Section 3.4.1.1). A letter dated September 17, 2003 from the North Carolina SHPO that affirms this finding is contained in Appendix A.

With the Parallel Bridge with Phased Approach alternatives (which are identical through the PINWR and including the Preferred Alternative), the nature of the Adverse Effect would be the visual impact of this alternative on this historic landscape and loss of access to Refuge features. As discussed in Section 4.3.2, the Phased Approach Alternative would introduce a sizable new linear man-made feature for approximately 10 miles (16.1 kilometers) through the Refuge. NC 12 through most of the Refuge would be elevated to a bridge in the existing NC 12 easement. The bridge would be at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level allowing for the bottom of the superstructure to be a minimum of 25 feet (7.6 meters) above mean high water (see Figure 2-24).

Like the All Bridge Alternative, the bridge with the Phased Approach alternatives (including the Preferred Alternative) would present a stark contrast with the natural character of the Refuge. In addition, at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (30 feet [9.1 meters] above ground), the Phased Approach bridges would be 15 feet (4.6 meters) higher than the height assumed for the All Bridge Alternative. The bridge would dominate views from the dunes lining the beach and, as the dunes disappear over time, it would also dominate views of the beach and ultimately the ocean. It would be uncharacteristic of the existing undeveloped and protected setting of the Refuge that makes it rare along the eastern US seaboard in terms of views and a resource for recreation activities.

The bridge with the Phased Approach alternatives (including the Preferred Alternative) would not directly affect existing facilities and activities shown in Figure 3-1b, but once built, direct access to the nature trails and the ponds area (built by the Civilian Conservation Corps in 1933) would no longer be available from NC 12. Access to the Refuge would only be at the north end via the ramps (described in Section 2.10) and south of the ponds where existing NC 12 is not threatened by shoreline erosion in the next 50 years. (See Section 4.5.3 for a further discussion of recreation impacts in the Refuge.)

(Former) Oregon Inlet US Coast Guard Station

Land within the National Register boundary of the (former) Oregon Inlet US Coast Guard Station would not be used with any of the Parallel Bridge Corridor alternatives.

With the Nourishment Alternative, the nourishment component would occur south of the (former) US Coast Guard Station. The new Oregon Inlet bridge would introduce two changes to the setting of the (former) US Coast Guard Station. First, as indicated in the discussion of impacts to the Refuge as an historic resource, the new bridge would be higher than Bonner Bridge. The current bridge enters Hatteras Island at an elevation of approximately 15 feet (4.6 meters). The new bridge would enter Hatteras Island at an elevation of approximately 70 feet (21.3 meters). The bridge and its roadway approach would drop to the existing grade over the course of approximately 2,700 feet (823.1 meters). The higher bridge structure would be introduced to views from the US Coast Guard Station towards Pamlico Sound. The second change with the Nourishment Alternative would be the construction of an access road to the parking lot that serves people fishing on Bonner Bridge's catwalks. It would go past (approximately 80 feet [24.4 meters] away) the Station building. If the (former) US Coast Guard Station is restored for reuse at its current site, this access road would provide convenient access to the Station. The Nourishment Alternative would have an Adverse Effect on the station because the greater height of the new Oregon Inlet bridge would alter the historic view and function of the station. Guards could watch 360 degrees for ships when the Station was built. The higher bridge also would alter the setting.

With the Road North/Bridge South Alternative, the changes in the setting of the (former) US Coast Guard Station would be similar to those for the Nourishment Alternative. The new Oregon Inlet bridge terminus would be approximately 120 to 250 feet (36.6 to 76.2 meters) west of the current bridge terminus on Hatteras Island. Again, the new bridge would be higher than Bonner Bridge as it enters Hatteras Island, in this case approximately 57 feet (17.4 meters) versus the current 15 feet (4.6 meters). The location of the terminus further west lengthens the distance from the end of the navigation zone to Hatteras Island; thus the bridge is lower when it reaches Hatteras Island than with the Nourishment Alternative. Access to the fishing parking lot and the station would be identical to that for the Nourishment Alternative. For the same reasons as the Nourishment Alternative, the Road North/Bridge South Alternative would have an Adverse Effect on the Station.

With the All Bridge Alternative, again the changes in the setting of the (former) US Coast Guard Station would be similar to those for the Nourishment Alternative. The new Oregon Inlet bridge terminus would be approximately 350 to 420 feet (107 to 128 meters) west of the current bridge terminus on Hatteras Island. Again, the new bridge would be higher than the old bridge as it enters Hatteras Island, in this case approximately 57 feet (17.4 meters) versus the current 15 feet (4.6 meters). The Oregon Inlet bridge would connect to the proposed 28-foot-high (8.5-meter) NC 12 maintenance bridge. Existing NC 12 and the existing road to the (former) US Coast Guard Station would provide access to the fishing parking lot and the station, respectively. A new

access road would not be introduced. For the same reasons as the Nourishment Alternative, the All Bridge Alternative would have an Adverse Effect on the station.

With the Phased Approach alternatives (including the Preferred Alternative), the new Oregon Inlet bridge would introduce changes to the setting of the (former) Oregon Inlet US Coast Guard Station. The new bridge would be higher than Bonner Bridge as it enters the Refuge and longer in the vicinity of the station. It would not come down to grade like the existing bridge but continue south. Bonner Bridge currently enters Hatteras Island at an elevation of approximately 15 feet (4.6 meters). The new bridge would enter Hatteras Island at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (see Figure 2-24).

With the Phased Approach alternatives (including the Preferred Alternative), the project would be phased in this area. In Phase I, the Oregon Inlet Bridge would be built and would end as a stub on Hatteras Island in the existing easement and adjacent to the station. Ramps would be built on either side of the bridge to bring traffic down to the existing road. During Phase II, expected to be built only a few years after Phase I, the bridge would be extended south and a second set of ramps would be built. The ramps would function as a highway interchange to bring NC 12 traffic down to the existing parking lot adjacent to the station. By the time Phase IV construction is complete, the bridge would not end until south of the Refuge ponds, well outside the viewshed of the station.

If it was considered desirable in the future to move the (former) Oregon Inlet US Coast Guard Station from its current site to a site north of Oregon Inlet, it would be more difficult to move the building across the Oregon Inlet bridge with the Phased Approach alternatives (including the Preferred Alternative) than with the other Parallel Bridge Corridor alternatives. With the other Parallel Bridge Corridor alternatives, the building could be moved from ground level to the bridge via the bridge travel lanes and shoulders (40 feet [12.2 meters] clear roadway width) with a grade of approximately 3.5 percent. With the Phased Approach alternatives, a narrower (18 feet [5.5 meters] including lane and shoulder) and steeper (approximately 5.3 percent grade) access ramp would need to be used. As with all alternatives, however, the building also could be moved across Oregon Inlet on a barge.

Like the other Parallel Bridge alternatives, these changes in visual setting with the Phased Approach alternatives (including the Preferred Alternative) would be an Adverse Effect on the (former) Oregon Inlet US Coast Guard Station from the perspective of its status as an historic resource. The Phased Approach alternatives would alter its setting and historic views from the station that were a part of its function. Guards could watch 360 degrees for ships when the station was built.

Chicamacomico Life Saving Station and Rodanthe Historic District

In the Rodanthe portion of the APE, the National Register-listed Chicamacomico Life Saving Station and several nearby houses form the National Register-eligible Rodanthe Historic District. Shoreline erosion modeling predicts that if high erosion trends continue, the Chicamacomico Life Saving Station and much of the associated historic district would be in the ocean in 2060. The first building in the Life Saving Station complex would be at the eroded shoreline in 2030. The Life Saving Station itself would be at the shoreline between 2050 and 2060 under high erosion conditions. None of the NC 12 maintenance alternatives are designed to affect this trend. They are only designed to maintain NC 12 in place or on a bridge. While the Road North/Bridge South and All Bridge alternatives are identical in their relationship to these two National Register-listed or -eligible resources, the relationship of the other Parallel Bridge Corridor alternatives would be different.

The Nourishment Alternative would involve nourishment to protect NC 12 north of the Life Saving Station and historic district. No dunes would be built in proximity to the Life Saving Station or historic district. The alternative would have No Effect on these historic resources.

The Road North/Bridge South and the All Bridge alternatives would be identical in the vicinity of the Life Saving Station and other historic district features. The alternatives would have an Adverse Effect on the Life Saving Station and the Rodanthe Historic District, as they would both pass through the district. These alternatives would approach Rodanthe on a bridge approximately 28 feet (8.5 meters) high through Pamlico Sound, and would enter the historic district at an elevation of approximately 18 feet (5.5 meters). Bridge foundations probably would be built every 100 feet (30.5 meters). The bridge component would end and the final fill leading down to an intersection at NC 12 would begin within the historic district. The alternatives would terminate at NC 12 across from the existing NC 12/Midgett Drive intersection, just to the south of the Chicamacomico Life Saving Station. The Road North/Bridge South and the All Bridge alternatives would both use land from non-contributing properties within the historic district, and would pass 14 feet (4.3 meters) and 320 feet (97.5 meters), respectively, from two contributing structures – the J. Frank Meekins Fish House and Levene W. Midgett House. These alternatives would be visible from the watchtower that is a part of the Life Saving Station building. Myrna Peters Road would be separated from NC 12. An alternative access road to NC 12 immediately south of the (former) Rodanthe School would be provided to the J. Frank Meekins Fish House and (former) Rodanthe School because their current access to NC 12 is via Myrna Peters Road. The Chicamacomico Life Saving Station would not leave control of its owners.

The Phased Approach/Rodanthe Bridge Alternative (Preferred) would involve building a bridge in the existing right-of-way with a one-lane/one-way frontage road on either side of the bridge substructure at grade to maintain access to adjoining properties. These features would fit into the existing right-of-way in the historic district, but would use the entire right-of-way width. NC 12 would remain on bridge until a point on NC 12 is reached that is 230 feet (70.1 meters) from the 2060 high erosion shoreline. This point occurs south of the historic district and, thus, the bridge would pass through the historic district. The bridge would be at its full height of 33.5 feet (10.2 meters) above mean high sea level (approximately 30 feet [9.1 meters] above ground) as it enters the district from the north (see Figure 2-24). It would begin to drop down to grade within the district and would be approximately 12.5 feet (4.0 meters) above ground at the southernmost point of the district. It would still be 30 feet (9.1 meters) above ground in front of the Chicamacomico Life Saving Station. Direct vehicle access across the right-of-way would be eliminated in the district. Connections between the frontage roads would be 963 feet (294.0 meters) south of the southern district boundary and 734 feet (224.0 meters) north of the northern district boundary. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would have an Adverse Effect on the Chicamacomico Life Saving Station and the district because of the change in the visual setting. The bridge would be a feature not in keeping with the historic setting of the structures contained within the district in terms of its height and structural components, and it would impede views across NC 12.

Like the Parallel Bridge Corridor with Nourishment Alternative, the Phased Approach/Rodanthe Nourishment Alternative would maintain NC 12 in Rodanthe using beach nourishment, so it would have No Effect on the Life Saving Station and historic district.

4.4.2 Archaeological Resources

There are no archaeological sites in the project area. In addition, underwater archaeological surveys identified no potentially significant submerged cultural resources within the project area.

(See Section 3.4.2.2 for a discussion of how this finding was made.) Letters from the SHPO concurring with this finding are included in Appendix A. Anomalies identified by remote sensing found buried in the sand appear to be modern debris (Krivor, 2004). If any archaeological resources (e.g., historic watercraft) are encountered during construction in areas with anomalies, construction work affecting the resource will cease immediately until the resource can be identified and assessed for National Register of Historic Places eligibility.

4.5 Parks and Recreation

This section addresses the land use impacts to the Seashore on Bodie Island and the Refuge. It also addresses the recreational use impacts to the Seashore and Refuge, as well as the Pamlico Sound. The No-Action Alternative, and the associated demolition and removal of Bonner Bridge, would result in the demolition of the fishing catwalks on Bonner Bridge. In addition, a ferry dock would need to be constructed within the Seashore with the No-Action Alternative; however, no other parks or recreation resources would be affected with the No-Action Alternative.

4.5.1 Cape Hatteras National Seashore Land Use Impacts on Bodie Island

These paragraphs summarize key components of impacts to the Seashore; a more detailed description of impacts is presented in the Section 4(f) evaluation in Chapter 5, as well as under other impact types presented throughout this chapter.

Activities, features, or attributes of the Seashore on Bodie Island would not be impaired substantially by a Pamlico Sound or Oregon Inlet (Parallel) bridge in the replacement bridge corridors, since NC 12 and Bonner Bridge were developed and planned to serve the Seashore. The replacement bridge corridors on Bodie Island are in the same general area as Bonner Bridge where it affects Seashore lands. No existing NPS facilities would be displaced.

The Pamlico Sound Bridge Corridor would require the permanent use of 7.3 acres (3.0 hectares) of the Seashore at Bodie Island for permanent fill and right-of-way over land. The Parallel Bridge Corridor would require the permanent use of 6.3 acres (2.6 hectares). All of this use would be on Bodie Island, where 6.3 acres (2.6 hectares) of Seashore land is currently used by Bonner Bridge. However, land within the Seashore currently occupied by Bonner Bridge would be returned to the Seashore after Bonner Bridge is demolished. All of the area filled to build the proposed bridge in the Pamlico Sound Bridge Corridor would be upland. No wetlands would be filled. The amount of wetland filled on Bodie Island to build the proposed bridge in the Parallel Bridge Corridor would be approximately 2.1 acres (1.8 hectares). Although NC 12 would be relocated slightly further to the west in the vicinity of the driveways to the Oregon Inlet Marina and the Oregon Inlet Campground, both driveways will remain in their current locations and access to these facilities would not be affected. There is a septic system leach field used by the Oregon Inlet Marina adjacent to the west side of NC 12 to the south of the Oregon Inlet Marina driveway. The exact location of this leach field is not known, but if it is determined during final design that the proposed project would impact the leach field, it will be moved to an appropriate adjacent location so that Oregon Inlet Marina operations would not be affected.

With either a Pamlico Sound Bridge or an Oregon Inlet bridge, charter fishing boats operating out of the Seashore's Oregon Inlet Marina and Fishing Center no longer would be able to use a natural channel known as "the crack" (Bridge to Old House Channel) to reach the navigation span of the Bonner Bridge instead of the Oregon Inlet Channel/Old House Channel maintained by the

USACE. The travel time to the ocean from the fishing center would be approximately 30 minutes longer via Oregon Inlet Channel/Old House Channel than via "the crack."

The dredging activity required to erect portions of a proposed bridge in the shallow portions of the Pamlico Sound Bridge Corridor would result in temporary changes in estuarine sediments and topography. Dredging the Pamlico Sound bottom would likely be needed for approximately 600 feet (183 meters) within the Seashore. With the Parallel Bridge Corridor behind Bodie Island, a temporary haul road could be built for erection of the Oregon Inlet bridge. The haul road and alternatives to the use of a haul road are described in Section 2.10.1.3. Approximately 2,400 feet (732 meters) of the temporary haul road would be within the Seashore; the haul road would be removed following construction. Dredging or a work bridge are alternatives to a haul road. Dredging of the Oregon Inlet bottom near Oregon Inlet Shoal and within the boundaries of the Refuge would likely be needed to float construction barges. The channel would be 120 feet (36.6 meters) wide and approximately 2,000 feet (610 meters) long. Elsewhere where the Seashore's boundaries are over water, the water depth is expected to be deep enough to float a construction barge without dredging. Dredging would be short-term and likely would refill to near pre-construction contours in areas of active, high-energy currents.

Separate contracts would be issued for construction of the proposed project in the Pamlico Sound Bridge Corridor and demolition and removal of Bonner Bridge. With an Oregon Inlet bridge, demolition could be within the same contract as construction.

With any of the replacement bridge corridor alternatives, construction activities within the Seashore would directly affect less than 1 acre (0.4 hectare) of potential nesting or foraging habitat for the piping plover (*Charadrius melodus*), which is federally-listed as a threatened species. According to the *Biological Assessment* (FHWA and NCDOT, 2008), up to 0.05 acre (0.02 hectare) of piping plover proposed critical habitat would be lost to fill and pile placement with the Phased Approach/Rodanthe Bridge Alternative (Preferred). With any of the alternatives, construction activities could potentially disrupt piping plovers that nest in the vicinity of the Oregon Inlet.

The Pamlico Sound Bridge Corridor's only impacts within the Seashore great enough to warrant mitigation would be those related to piping plover nesting areas and construction dredging and/or construction access (haul road, dredging, and/or work bridge) impacts just west of Bodie Island. On Bodie Island, this conclusion also would be true for the Parallel Bridge Corridor. The approach to mitigation for these impacts is described in Sections 4.7.10 and 4.13.6.

The land use impacts to the Seashore on Bodie Island of the No-Action Alternative would involve the impacts associated with the demolition and removal of Bonner Bridge, as well as the construction and operation of small-scale ferry service to maintain some access to Hatteras Island. (See Section 2.2.6.3 for a description of potential impacts.) Without a bridge, there would be no impediments to navigation for boats operating out of the Oregon Inlet Marina and Fishing Center.

4.5.2 Pea Island National Wildlife Refuge Land Use Impacts on Hatteras Island

The replacement bridge corridor alternatives would vary in their effect on the activities, features, and attributes of the Refuge (in an area held in common with the Seashore) on Hatteras Island.

The Pamlico Sound Bridge Corridor would not use land from the Refuge. The Parallel Bridge Corridor, including the two Phased Approach alternatives (including the Preferred Alternative),

would be within the Refuge (in an area held in common with the Seashore) on Hatteras Island. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would be built and maintained within the existing NC 12 easement. Thus, no new Refuge lands would be used by this alternative. The Parallel Bridge Corridor alternatives would affect land from the Refuge as follows:

- Nourishment. 19.7 acres (8.0 hectares) associated with new dunes plus nourishment of 6.3 miles (10.1 kilometers) of the seashore within the Refuge. NC 12 would remain in its current easement. A new access road to the Oregon Inlet area parking lot would involve 0.2 acre (0.07 hectare) of new right-of-way.

- Road North/Bridge South. 90.3 acres (36.6 hectares) of new 100-foot (30.5-meter) wide right-of-way would be used for the relocated NC 12 as a roadway and bridge. Approximately 2,961 feet (903 meters) of new bridge would be built over Refuge lands. A new access road to the Oregon Inlet area parking lot would involve 0.2 acre (0.07 hectare) of new right-of-way. Ultimately, 2.9 acres (1.2 hectares) of area would be used by three new dunes, with the earliest built in 2030.

- All Bridge. 89.6 acres (36.2 hectares) of new 100-foot (30.5-meter) wide right-of-way would be used for the relocated NC 12 as a roadway and bridge. Approximately 7.6 miles (12.2 kilometers) of new bridge would be built over Refuge lands. A new access road to the Oregon Inlet area parking lot would involve 2.6 acres (1.1 hectare) of new right-of-way.

- Phased Approach Alternatives (including the Preferred Alternative). The total area of disturbance within the existing easement in the Refuge would be 3.7 acres (1.5 hectares) permanent and 48.5 acres (19.6 hectares) temporary. With the Phased Approach/Rodanthe Nourishment Alternative, nourishment would occur on 1,500 feet (457.2 meters) of seashore within the Refuge.

The above areas include fill in USACE jurisdictional wetland as follows:

- Nourishment. 1.2 acres (0.5 hectare);

- Road North/Bridge South. 48.7 acres (19.7 hectares);

- All Bridge. 5.9 acres (2.4 hectares); and

- Phased Approach Alternatives (including the Preferred Alternative). 3.1 acres (1.3 hectares) permanent and 6.5 acres (2.6 hectares) temporary.

The Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor with All Bridge Alternative (with the exception of the continued presence of the terminal groin at the north end of Hatteras Island) would support the desire of officials responsible for the Refuge and the Seashore to not stabilize the Outer Banks artificially, but rather to let natural processes take their course. The two Phased Approach alternatives (including the Preferred Alternative) likewise would support this desire, with two exceptions: 1) the continued presence of the terminal groin and 2) the 1,500 feet of nourishment on Refuge beaches at the south end of the Refuge in association with Phased Approach/ Rodanthe Nourishment Alternative.

The Parallel Bridge Corridor with Road North/Bridge South Alternative would generally support the desire of officials responsible for the Refuge and the Seashore to not stabilize the Outer Banks artificially, but rather to let natural processes take their course. Exceptions would be the

continued presence of the terminal groin, the three dunes that would eventually be built, and were a breach to occur in the Refuge that would need to be closed to maintain NC 12. The Parallel Bridge Corridor with Nourishment Alternative would not support this desire since it would maintain NC 12 by stabilizing the shoreline with nourishment and protecting NC 12 with dunes.

Protected species within the Refuge also could be affected, including sea turtles, the piping plover, and the seabeach amaranth, as discussed in Section 4.7.9.

The approach to mitigation for these impacts is described in Section 4.6.8.

4.5.3 Cape Hatteras National Seashore/Pea Island National Wildlife Refuge Recreational Use Impacts

As described in Section 3.5, visitors rely on NC 12 to reach various recreational activities within the Seashore and Refuge. These activities include fishing, cycling, hiking, walking, and birding. Neither replacement bridge corridor alternative would affect recreational use in the Seashore on Bodie Island. The NPS and the USFWS share management duties where the boundaries of the Seashore overlap with those of the Refuge at the northern end of Hatteras Island. The NPS is responsible for visitors and visitor facilities, while the USFWS is responsible for wildlife management. Because the NPS has recreation management responsibilities on both sides of Oregon Inlet, the discussion of the recreational use impacts for this area is combined in this section.

4.5.3.1 Pea Island National Wildlife Refuge Access

The replacement bridge corridor alternatives would maintain access by road from Hatteras Island to Bodie Island and mainland Dare County. Access for visitors to the Refuge would be maintained, but in the case of the Pamlico Sound Bridge Corridor, the access north of Rodanthe would not likely be on a paved road. Road access to the Refuge would change, but not be completely eliminated, with most of the Parallel Bridge Corridor alternatives (including the Preferred Alternative).

Pamlico Sound Bridge Corridor

With the Pamlico Sound Bridge Corridor, highway access from Bodie Island to Hatteras Island no longer would pass through the Seashore and Refuge, but the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge and the portion of the Seashore north of Rodanthe for recreational users. However, the method of access likely would be something different than a paved road between Rodanthe and Oregon Inlet.

The loss of paved road access with the Pamlico Sound Bridge Corridor would inconvenience the Refuge's visitors, create economic impacts for Dare County (although not likely to be major), and cause an Adverse Effect to the National Register-listed (former) US Coast Guard Station. When considering these impacts, it is important to keep in mind that recreation is not defined as the primary purpose of the Refuge. Executive Order 7864 that created the Refuge reserved the area for migratory birds and other wildlife to advance the purposes of the Migratory Bird Conservation Act of 1929. The primary purpose of the Refuge is to be a refuge and breeding ground for migratory birds and other wildlife.

Participants in all types of visitor activities would be affected by the loss of paved road. The nearest paved road would be where NC 12 would terminate at the southern boundary of the Refuge at Rodanthe. The distance from the new south terminus of NC 12 (Refuge boundary) to various Refuge facilities would be:

- Boat ramp: 4.7 miles (7.6 kilometers);
- North Pond Wildlife Trail and Visitor Center: 7.7 miles (12.4 kilometers);
- Salt Flats Wildlife Trail: 9.3 miles (15.0 kilometers); and
- Fishing parking lot at Oregon Inlet: 11.8 miles (19.0 kilometers).

The distance to beach access would range from beach access being immediately adjacent to the terminus of NC 12 at the southern boundary of the Refuge, to 11.8 miles (19.0 kilometers) to the beach at the Oregon Inlet area. As described in Section 4.1.5.3, how this inconvenience would affect decisions of whether to visit the Refuge depends on the activity, as well as the availability of a similar experience elsewhere on the Outer Banks.

Parallel Bridge Corridor

Paved road access would continue in the Refuge with the Parallel Bridge Corridor. The Nourishment Alternative would change the location of the access to the fishing parking lot near Oregon Inlet, but all other access to recreational facilities within the Refuge would be unchanged. The Road North/Bridge South Alternative would alter trail and beach access slightly for most of the Refuge by moving NC 12 further west. At the south end of the Refuge, the Rodanthe area bridge would bypass the southern 1.6 miles (2.6 kilometers) of the Refuge. The bridges associated with the All Bridge Alternative would reduce Refuge access the second most of the five Parallel Bridge Corridor alternatives. Three access points would be provided in the Refuge: at the north end of the Refuge near the fishing parking lot, at the start of the Salt Flats Wildlife Trail (i.e., at the north end of the ponds), and south of the ponds (for a distance of approximately 2 miles [3.2 kilometers]). The All Bridge Alternative would bypass the Refuge Visitor Center, the North Pond Trail, the Refuge's headquarters, and the boat ramp. The Refuge Visitor Center and headquarters would be threatened by beach erosion by 2020 with all but the Nourishment Alternative and would need to be relocated.

The bridges associated with the two Phased Approach alternatives (including the Preferred Alternative) would reduce Refuge access the most of the various Parallel Bridge Corridor alternatives. Once complete, two access points would be provided within the Refuge: at the north end of the Refuge at the fishing parking lot and south of the ponds (for a distance of approximately 2.1 miles [3.4 kilometers]). The Phased Approach alternatives (including the Preferred Alternative) would bypass the Refuge Visitor Center, the Salt Flats Wildlife Trail, the North Pond Trail, the Refuge's headquarters, and the boat ramp. The two trails are the Refuge's primary opportunities for bird watching. Opportunities to stop and park for access to the ocean and beach for surfing and fishing would be limited to the two locations indicated.

Access to recreation use would be unchanged after the completion of Phase I of the Phased Approach alternatives (including the Preferred Alternative). Upon completion of Phase II, the length of the remaining NC 12 at-grade would be approximately 6.8 miles (10.9 kilometers). The at-grade portion would include the Refuge's headquarters and the boat ramp. Upon completion of Phase III, the length of NC 12 remaining at-grade would be approximately 4.6 miles (7.4 kilometers), and would no longer serve any of the existing Refuge facilities. Upon completion of Phase IV, the length of NC 12 at-grade would be approximately 2.1 miles (3.4 kilometers). Access to various facilities in the Refuge would change with the various phases of the Phased Approach as follows:

	Approximate Distance from Nearest NC 12 Access Point to these Facilities in miles (kilometers)			
	Phase I	*Phase II*	*Phase III*	*Phase IV*
• Refuge Visitor Center	Adjacent	0.3 (0.5)	0.3 (0.5)	3.6 (5.8)
• Salt Flats Wildlife Trail	Adjacent	0.1 (0.2)	0.1 (0.2)	2.5 (4.0)
• North Pond Trail	Adjacent	0.2 (0.3)	0.2 (0.3)	3.5 (5.6)
• Refuge's headquarters	Adjacent	Adjacent	0.6 (1.0)	1.6 (2.6)
• Boat ramp	Adjacent	Adjacent	0.8 (1.3)	0.8 (1.3)

Given that the Refuge Visitor Center and headquarters would be threatened by beach erosion by 2020, the Refuge could choose to move these facilities to a more convenient location.

The No-Action Alternative would remove roadway access across Oregon Inlet to Hatteras Island. This change would dramatically lessen the ability of visitors to reach recreational resources throughout the Refuge.

4.5.3.2 Fishing at Oregon Inlet

Bonner Bridge has catwalks that are used by fishermen. The catwalks are maintained by the NCDOT. Catwalks at Oregon Inlet likely would not be included on a replacement bridge in the Pamlico Sound Bridge Corridor because the new bridge would not terminate at the northern end of Hatteras Island.

The Oregon Inlet bridge with the Parallel Bridge Corridor would terminate at the northern end of Hatteras Island. For safety reasons, however, access via catwalks on a bridge in this corridor is not likely. Because of the height of the new bridge, those fishing locations would be approximately 40 feet (12.2 meters) above the water at the shoreline and approximately 65 feet (19.8 meters) above the water by the end of the first span (approximately 400 feet [122.0 meters] offshore) with all but the Phased Approach alternatives (including the Preferred Alternative). The Phased Approach alternatives would be at an elevation of approximately 33.5 feet (10.2 meters). The height of such a catwalk increases the likelihood of serious, if not fatal, injuries as a result of falls.

Opposition to not replacing fishing access was expressed at the public hearings. Fishing is a popular tourist recreational activity on this part of Hatteras Island. The NCDOT would work with the USFWS, the NPS, Dare County, and other appropriate agencies to decide how to restore some kind of fishing access. The USFWS and NPS have indicated that their objective is that fishing access be provided at the north end of Hatteras Island at Oregon Inlet, although fishing does not have to be provided from catwalks mounted on the new bridge.

At this time, one viable approach for the Pamlico Sound Bridge Corridor, Parallel Bridge Corridor with Road North/Bridge South, and Parallel Bridge Corridor with All Bridge alternatives appears to be leaving a portion of the existing Bonner Bridge for fishing. This cannot be done with the other three alternatives, which assume the new bridge terminates at Hatteras Island within the existing NC 12 easement. To maintain a portion of Bonner Bridge as a fishing pier, some government body or non-governmental organization would have to take responsibility for pier operation, maintenance, and liability. Construction of a "boardwalk" on top of the riprap that currently blankets the northern shore of Hatteras Island is another option. Accommodating fishing from the terminal groin is not considered a viable option. Fishing from the groin is considered very dangerous because of the rapid currents adjacent to the groin and the uneven surface of the groin.

When Phase I of the two Phased Approach alternatives (including the Preferred Alternative) – the new Oregon Inlet bridge – is complete, the temporary traffic detour bridge could be left in place to be used as a fishing pier, replacing the catwalks. This also could occur with the Nourishment Alternative, which also would involve replacing the bridge in the existing right-of-way. A traffic maintenance bridge is not needed with the other replacement bridge corridors. As is the case with maintaining a portion of Bonner Bridge as a fishing pier, some government body or non-governmental organization would have to take responsibility for fishing pier operation, maintenance, and liability. The Design-Build Contractor also may propose other options to provide for public fishing access.

If the temporary detour bridge is left in place as a fishing pier, it would be approximately five feet (1.5 meters) higher than the current catwalks on Bonner Bridge. According to Larry Hardham, President of the Cape Hatteras Anglers Club (personal communication, November 16, 2006), being closer to the water is better for fishing. Mr. Hardham also indicated that fishing is better the further out on the catwalk one stands. The fishing pier would be approximately the same distance into Oregon Inlet as the current catwalks. The pier would be much wider than the catwalks (4.5 feet [1.4 meters] versus 26 feet [7.9 meters]), providing fishermen with more room to move about than on the current catwalks. There also would be some shade where the fishing pier would be under one of the exit ramps to the existing parking lot at the north end of Hatteras Island.

With the No-Action Alternative, the fishing catwalks would be removed with the demolition and removal of Bonner Bridge at the end of its service life.

4.5.3.3 Other Recreational Activities

The Parallel Bridge Corridor with Nourishment Alternative would maintain NC 12 within in its existing right-of-way. Refuge facilities would thus be unaffected and would be protected from loss resulting from future shoreline erosion. The Road North/Bridge South Alternative would cross the Salt Flats Wildlife and North Ponds trails near their respective starting points. In the case of the North Pond Trail, which originates at the Visitor Center, users starting at the Visitor Center would have to cross the relocated NC 12. Warning signs and markers would be placed at the crossing. For the Salt Flats Wildlife Trail, the starting point and associated parking on NC 12 would be moved to the new NC 12 location approximately 270 feet (82.3 meters) to the west. A new driveway would be built to the Visitor Center, which would be approximately 550 feet (167.6 meters) east of the relocated NC 12. As described above in Section 4.5.3.1, the All Bridge Alternative would bypass the Refuge Visitor Center, the North Pond Trail, the Refuge's headquarters, and the boat ramp. The Refuge Visitor Center and headquarters would thus be relocated approximately a decade earlier than they would be as a result of an approaching shoreline. Access to the North Pond Trail would remain via the Salt Flats Wildlife Trail, but the two trails would not meet until approximately 2 miles (3.2 kilometers) away from the start of the Salt Flats Wildlife Trail.

Several recreation activities that occur on Hatteras Island, including fishing, hiking, surfing, wind surfing, kite boarding, swimming, ocean kayaking, birding, use of the Visitor Center and Refuge headquarters, would be affected by the two Phased Approach alternatives (including the Preferred Alternative). The effects on birding and use of the Visitor Center and Refuge headquarters would be limited to access impacts, which are discussed in the paragraphs above. Other activities would be directly affected.

The nature of the impacts to other recreation activities would vary over time, since while initially on land, the bridges associated with the Phased Approach alternatives (including the Preferred

Alternative) ultimately would move to the shoreline and then offshore in the Atlantic Ocean as the shoreline erodes underneath the bridges. Thus, unlike the other Parallel Bridge Corridor alternatives, the Phased Approach alternatives (including the Preferred Alternative) would directly affect activities on the beach front, including all of the beach and water activities listed in the previous paragraph.

Discussions with Larry Hardham, President of the Cape Hatteras Anglers Club (personal communication, November 16, 2006), yielded the conclusion that where access remains, the bridges themselves could affect fishing from the beach from the perspective of the type of fish present. Once bridge foundations are in the ocean, the types of fish that congregate around the shore could change in response to the presence of the structure. Certain types of fish that are prevalent today could move to other locations, while other types of fish could be attracted to the structure in the ocean. This could attract some fishermen looking for the kind of fish attracted to the new structure. Striper fishing, for example, which is very popular among fishermen in the fall, could be better when the bridge is in the ocean, as stripers are more prevalent near structures. Fishermen looking for the kind of fish that would move because of the structure would need to look for other places to fish from the shoreline, according to Mr. Hardham.

As noted in Section 4.5.3.1, the Phased Approach alternatives (including the Preferred Alternative) would ultimately eliminate access to Refuge hiking trails and reduce beach access. As the shoreline erodes and the Phased Approach bridges move onto the beach, hiking and other beach activities on the shoreline could still take place, but they would not occur in today's undisturbed natural setting. As the shoreline continues to erode, the structure would move further into the ocean and beach activities would return to their original unimpeded state, except that the structure would be visible in the ocean as it parallels the shoreline at varying distances from the beach (up to 930 feet [283.5 meters] offshore). To the extent that certain sections of the bridged roadway still would be on land or on the beach, beach activities would be affected, but not precluded.

The impacts to surfing would be more severe. Surfers choose their location to surf based upon where the waves break. As the shoreline changes, so too will the location of the best waves on the Refuge for surfing. Like the All Bridge Alternative, the reduction of access associated with the Phased Approach alternatives (including the Preferred Alternative) would increase the distance to access the best waves for surfing or perhaps take them out of a reasonable walking range. This change would be gradual with the Phased Approach alternatives as noted in the section on access above.

Once the Phased Approach alternatives' bridges (including the Preferred Alternative) are in the ocean, the ability to surf in a particular area would be eliminated. According to Julie Leavel of the Outer Banks District of the Eastern Surfers Association (personal communication, November 21, 2006), surfers usually go 50 to 75 feet (15.2 to 22.9 meters) into the ocean and sometimes up to 150 feet (45.7 meters) to find the best waves for surfing. How far out surfers travel into the ocean depends upon where the waves break. The introduction of a bridge structure to the ocean would change how and where the waves break, which would interfere with the swells in such a way that the waves would no longer be conducive for good surfing as is found in certain areas of the Refuge today. This would essentially eliminate surfing in this area. In addition, the presence of bridge piles every 120 feet (36.6 meters) in areas where the bridges would be less than 150 feet (45.7 meters) from shore would be a safety hazard.

4.5.4 Pamlico Sound Recreational Use Impacts

For recreational users of the Pamlico Sound, such as wind surfers, kayakers, and kite boarders, the Pamlico Sound Bridge Corridor would place an obstruction in the Sound as the bridge moves from shore at Rodanthe to a point approximately 5 miles (8 kilometers) west of Hatteras Island where the bridge corridor then would proceed north. The ability of recreational users to pass from one side of the bridge approach to the other, particularly for wind surfers and kite boarders, would be limited by its 140- to 150-foot (42.7- to 45.7-meter) span length between piers and vertical clearance of approximately 10.0 feet (3.1 meters) above mean high water (outside the navigation zone).

The Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives also would place an obstruction in the Sound as the Rodanthe area bridge moves out from shore in the Refuge to a point about 1,500 feet (480 meters) west of Hatteras Island. This bridge would have a 100-foot (30.5- meter) span length between piers and vertical clearance of approximately 10.0 feet (3.1 meters) above mean high water. Because of this bridge's close proximity to the shore, the impacts to recreational users would be more substantial. The Nourishment Alternative and the two Phased Approach alternatives (including the Preferred Alternative) would not affect the use of Pamlico Sound.

Numerous additional opportunities exist for these activities, however. Near the project area, these activities occur primarily south of the replacement bridge corridor alternatives.

Near the northern end of the Pamlico Sound Bridge Corridor, activities such as windsurfing, kayaking, and kite boarding are not common; the Pamlico Sound Bridge Corridor would not affect these non-motorized watercraft activities in this area. This area of the Pamlico Sound is used primarily for fishing and by other commercial and recreational vessels (see Section 4.1.7).

The No-Action Alternative would not affect the use of Pamlico Sound but would remove roadway access across Oregon Inlet to Hatteras Island. This change would dramatically lessen the ability of visitors to reach all recreational resources on Hatteras Island.

4.6 Coastal Conditions

This section discusses the impact of the detailed study alternatives on coastal conditions from the perspective of: inlet migration, profile, and gorge alignment; flooding during major storms; performance of the terminal groin; navigation channel dredging operations; natural overwash; island breach in the Refuge; and off-shore coastal processes (with the Phased Approach alternatives [including the Preferred Alternative]).

4.6.1 Inlet Migration, Profile, and Gorge Alignment

A bridge within the replacement bridge corridor alternatives would have a negligible effect on Oregon Inlet migration, profile, and gorge alignment other than the continued effect of the presence of the terminal groin with the Parallel Bridge Corridor alternatives (including the Preferred Alternative). These processes are driven by the movement of sediment along the ocean shoreline and tidal hydraulics processes within Oregon Inlet. A bridge within the replacement bridge corridor alternatives would represent a very minor additional component in the Oregon Inlet system, especially considering there is already a bridge within the inlet. In any case, storm events that typically cause the major adjustments to the inlet through increased wave activity and

water flows would vastly overshadow any minor effects the proposed bridge in Pamlico Sound or across Oregon Inlet might have on inlet processes.

4.6.2 Flooding During Major Storms

All of the replacement bridge corridor alternatives, as well as the existing Bonner Bridge and NC 12, are within the floodplain discussed in Section 3.6.1. In addition, all of the replacement bridge corridor alternatives, as well as the existing Bonner Bridge and NC 12, are partially within coastal flood zones with a velocity hazard because of wave action. According to Federal Emergency Management (FEMA) floodplain maps (Figure 3-4), all of the Parallel Bridge Corridor alternatives would be subjected to wave heights as high as 11 feet (3.4 meters) over Oregon Inlet and in several other locations along the corridor, but could be subjected to wave heights as high as 13 feet (4.0 meters) near the southern end of South Pond. Existing Bonner Bridge and NC 12 also are subject to the same wave heights. The Pamlico Sound Bridge Corridor alternatives would be subjected to wave heights as high as 10 feet (3.0 meters) in Pamlico Sound near their southern terminus in Rodanthe.

4.6.2.1 Significant Encroachment

FHWA policies and procedures for the location and hydraulic design of highway encroachments on floodplains are defined in 23 CFR 650, Subpart A (Location and Hydraulic Design of Encroachments on Floodplains). With respect to floodplain highway encroachments, it is the policy of the FHWA "to avoid significant encroachments, where practicable." According to 23 CFR 650, Subpart A:

> "*Significant encroachment* shall mean a highway encroachment and any direct support of likely base floodplain development that would involve one or more of the following construction or flood-related impacts:
>
> – A significant potential for interruption or termination of a transportation facility which is needed for emergency vehicles or provides a community's only evacuation route;
>
> – A significant risk, or;
>
> – A significant adverse impact on natural and beneficial floodplain values."

Transportation Facility Interruption

All of the proposed replacement bridge corridor alternatives, as well as existing NC 12 through the project area, meet the definition of "significant encroachment" in that they include a road at an elevation below the storm surge. This also is true for the balance of Hatteras Island and the development served by NC 12. However, all of the proposed replacement bridge corridor alternatives would reduce the risk of NC 12 overwash and temporary closure within the project area in comparison to the risk that exists today through (depending on the alternative) beach nourishment, road relocation back from the shoreline, and bridging. The use of a bridge to replace parts of the existing NC 12 road with the Pamlico Sound Bridge Corridor, All Bridge, and Phased Approach alternatives (including the Preferred Alternative) would raise those parts of NC 12 above the storm surge. They also would either bypass or bridge potential Hatteras Island breach locations within the project area. All of the bridges, however, ultimately end at existing NC 12 below the storm surge, including the ends of the bridges on Bodie Island and Hatteras Island, and the 2.1- to 2.3-mile (3.3- to 3.7-kilometer) segment of NC 12 unchanged by the Parallel Bridge Corridor alternatives.

Dare County recognizes the risks associated with the storm surge and has an emergency management program that tracks storms and orders the voluntary evacuation of Hatteras Island and the entire Outer Banks prior to a storm surge. Dare County also has a helicopter to transport patients to area hospitals if NC 12 is severed as a result of a storm. NCDOT maintains emergency ferry docks and a channel across Pamlico Sound between Rodanthe and Stumpy Point to provide an alternate route of travel if NC 12 is severed between Rodanthe and Oregon Inlet. NCDOT has the capability and does mobilize equipment needed to begin re-opening NC 12 immediately after a storm passes.

Significant Risk

None of the alternatives would create a significant risk beyond risks associated with development on the Outer Banks that exist today. Risks on the Outer Banks are associated with storms and their consequences. All of the alternatives (including the Preferred Alternative) were developed taking into account the presence of storms and their potential impact on island change and the integrity and operation of the alternatives. The bridge superstructure associated with the replacement bridge corridor alternatives (including the Preferred Alternative) would be elevated above the highest potential water level.

The alternatives do vary in terms of their mitigation of the risk of NC 12 being closed as a result of an island breach. The Pamlico Sound Bridge Corridor alternatives would bypass potential breach locations. The Parallel Bridge Corridor with All Bridge and Phased Approach Rodanthe Bridge (Preferred) alternatives both bridge potential breach locations. Section 4.6.7 discusses in detail the relationship between all of the alternatives and the potential breach locations.

Impact to Beneficial Floodplain Values

Beneficial floodplain values were described in Section 3.6.1. The replacement bridge corridor alternatives would not have a significant adverse impact on natural and beneficial floodplain values.

The piles of the bridge substructure would not affect existing hydraulics, since the size of Pamlico Sound and the low water velocities would combine to create a situation where the small area blocked by the alternatives would not create backwater or adverse hydraulic conditions.

From the perspective of the beneficial floodplain values associated with natural barrier island evolution, as well as the ecological change and habitat creation associated with barrier island evolution, most of the alternatives (including the Preferred Alternative) would benefit these values. Except for the alternatives that involve the retention of the artificial dunes (Parallel Bridge Corridor with Nourishment and to a limited extent the Road North/Bridge South and Phased Approach/Rodanthe Nourishment alternatives), the project alternatives would restore natural shoreline overwash, as discussed in Section 4.7.7.

4.6.2.2 Only Practicable Alternative Finding

According to 23 CFR 650, Subpart A, a proposed action which includes a significant encroachment shall not be approved unless the FHWA finds that the proposed significant encroachment is the only practicable alternative. Practicable replacement bridge corridor alternatives must be within the floodplain because the area to be served, as specified in the project's Statement of Purpose and Need in Chapter 1, is within the floodplain. As such, alternatives that do not involve a significant encroachment were not considered. The replacement bridge corridor alternatives conform to applicable State and local floodplain protection standards because they would not affect the storm surge elevation.

4.6.3 Performance of the Terminal Groin

The performance of the terminal groin would not be affected by any of the replacement bridge corridor alternatives or the No-Action Alternative. With the Pamlico Sound Bridge Corridor and the No-Action Alternative, there would no longer be a bridge landing on the north end of Hatteras Island, so the terminal groin no longer would be needed (the stated purpose for the groin in the USFWS permit that allowed the groin's construction is to protect the south end of Bonner Bridge). If USFWS officials ask the NCDOT to remove the groin following completion of the demolition and removal of Bonner Bridge, the NCDOT and representatives of the USFWS would assess the impacts of groin removal in a separate environmental study, as needed, prior to any final decision to remove the terminal groin.

With the Parallel Bridge Corridor, the terminal groin would need to be retained to protect the road south of the southern terminus of the new Oregon Inlet bridge. The NCDOT would apply for a new permit for any of the Parallel Bridge Corridor alternatives (including the Preferred Alternative). Hydraulic analyses associated with the design of the Parallel Bridge Corridors alternatives that include bridges through the northern part of Hatteras Island would incorporate the potential for either the eventual terminal groin removal or the groin's flanking. The potential affect of groin removal or flanking on Hatteras Island is addressed in Section 3.6.3.5.

4.6.4 Navigation Channel Dredging Operations

A replacement bridge within either of the replacement bridge corridors would make navigation channel dredging operations easier to undertake by reducing the frequency and size of dredging operations from what is required today.

The proposed bridge in either corridor would have one navigation zone (see Section 2.9.2) for boats passing through Oregon Inlet.

The proposed bridge in the Pamlico Sound Bridge Corridor and its navigation zone would be west of Oregon Inlet in Pamlico Sound, where sand movement is less. This change alone could reduce the amount of dredging required to maintain a channel through Oregon Inlet compared to the existing situation with Bonner Bridge. The location of the zone would be determined in coordination with the USACE. The USACE currently maintains the Oregon Inlet Channel/Old House Channel. As discussed in Section 3.6.3, movement of Oregon Inlet over the life of the proposed bridge could shift the natural channel gorge to the Davis Channel area. This eventuality would be addressed in conversations with the USACE. The NCDOT's goal would be to place the navigation zone of a bridge in the Pamlico Sound Bridge Corridor in a location that facilitates channel maintenance over the full life of the bridge.

A bridge across Oregon Inlet in the Parallel Bridge Corridor would have a series of navigation spans (or zone) with a minimum 200 feet (61 meters) of horizontal clearance. The main navigation span of Bonner Bridge has 130 feet (39.6 meters) of navigation clearance. The navigation zone on Bonner Bridge is 504 feet (153.6 meters). With the two Phased Approach alternatives (including the Preferred Alternative), that navigation zone would be 3,300 feet (1,006 meters) long. With the other Parallel Bridge Corridor alternatives, the zone would extend across the width of the inlet (up to 5,000 feet [1,524 meters]). The shorter distance with the Phased Approach alternatives is necessitated by the inclusion of ramps accessing the north end of Hatteras Island from the alternative's bridges. Bonner Bridge is limited to three navigation spans. A longer navigation zone provided by the Parallel Bridge Corridor alternatives would allow the dredged navigation channel to be placed more readily at the natural inlet gorge and likely would

reduce the amount of dredging at both the bridge and within the throat of the inlet, where a natural gorge exists. This benefit would be greater with the longer navigation zone associated with the Nourishment, Road North/Bridge South, and All Bridge alternatives.

With all alternatives, some additional dredging west of existing Bonner Bridge could be required to connect the natural inlet gorge to the channels maintained within Pamlico Sound in cases where the natural inlet gorge moves well beyond the location of Bonner Bridge navigation spans. In those cases, the USACE would have to determine, based on experience, whether it would be easier or more efficient to extend the back channels by dredging to meet the natural inlet gorge, or to force the inlet channel to take a different path than it might otherwise take on its own. The best strategy to be followed at any given time would depend on the complex and ever changing variation in shoal and channel locations that will naturally occur on the soundside of the Parallel Bridge Corridor. The greater latitude in potential channel locations that the Parallel Bridge Corridor would allow, however, would result in a net decrease in the dredging effort within the inlet.

The ocean bar channel dredging, which accounts for the majority of the dredging at Oregon Inlet, would not be affected by either of the replacement bridge corridor alternatives or the No-Action Alternative.

4.6.5 Natural Overwash

Overwash is the natural landward transport of sand and water. The deposit is called a washover fan. Overwash is a storm generated process that serves a critical function in barrier island evolution, as it is the source of sand for the soundside of the island. In this way, sand is removed from the beach and dune system and builds up on the soundside. The length of penetration of a washover fan is a function of the sediment supply, storm characteristics, and topography. Overwash occurs where the island is low relative to the storm surge/wave run-up and/or where breaks in the dune system create conduits for flow to be funneled from the oceanside landward. The dune breaks may be present before the storm or may develop during the storm as the dune erodes from the oceanside. The washover fan provides not only elevation through sediment deposition, but it creates new habitat by covering existing habitat and providing a bare sand flat for new populations. Removing sand from the washover interrupts the process of barrier island rollover by putting the sand back in the dune system.

As is evident in NC 12 maintenance activity data from NCDOT, overwash has become a substantial factor in determining the need for maintenance. Twelve cleanup projects since 2003 have been attributed to overwash, primarily in the Canal Zone, Sandbag, and Rodanthe 'S' Curves hot spots. In order to minimize the impact of NC 12 on overwash processes, the road could either be moved landward beyond the point of expected washover or elevated. The following alternatives would minimize the affect on overwash fans through at least 2060:

- Pamlico Sound Bridge Corridor alternatives, since they remove NC 12 from Hatteras Island north of Rodanthe.

- Parallel Bridge Corridor with Road North/Bridge South, since it moves NC 12 beyond the 2060 high erosion shoreline at the north end of Hatteras Island and places NC 12 on a bridge at the south end of the project area, with the exception of three locations where dunes are proposed late in the project's design life.

- Parallel Bridge Corridor with All Bridge and Phased Approach alternatives (including the Preferred Alternative) (in bridging areas) by placing NC 12 on a bridge through most of the project area. In the case of the Phased Approach, interruption of overwash fans could occur until each Phase is implemented, as discussed in Section 4.6.8.6.

With NC 12 on bridges, the piles supporting the structure would interfere locally with the overwash; however, the overall structure would be very porous, and the overall impact should be restricted to the areas around the piles. The overwash would be streamlined between the pilings in a group where the velocities would be slightly greater than the velocities away from the group because of flow constriction. This might serve to create points of greater landward penetration resulting from higher flow velocities, which would correspond to each bridge foundation. There also would be some local scour around the piles providing an additional source of sand for the washover fan. Once the road is elevated, there would be no need to remove the sand from the washover and rebuild the dune.

The alternatives that would involve nourishment and extensive dune building also would interrupt the overwash process. When overwash occurs, the replacement of sand on the dunes would interrupt the overwash process; the impact could be reduced by removing the sand from the road (defined to be pavement and easement), but leaving the washover fan created landward of the NC 12 right-of-way. Not as much sand then would be available for post storm dune repairs, thereby leaving the road more vulnerable to overwash in the next event. The road could then require more extensive post storm repairs as a result of the weir flow damage, in which the pavement acts like a weir (dam), and the high velocities scour the sand on the landward side of the highway.

4.6.6 Accelerated Sea Level Rise

Section 3.6.3.3 noted that historic sea level rise is accounted for in the project's shoreline forecasts and described in two potential scenarios for accelerated sea level rise (scenarios 2 and 3). As a result of recently published research on global climate change and sea level rise, FHWA wanted to consider how the new information on global climate change may affect the development and implementation of this project. FHWA hosted a Peer Exchange workshop on May 14 to 15, 2008, in Raleigh, North Carolina. The peer exchange included a panel of coastal engineering and geology experts with knowledge of the local area, as well as experts with knowledge of recent research on global climate change. The objectives of the workshop were to identify recent scientific research on global climate change effects and to relate how that research can help inform the development of the Bonner Bridge Replacement project. The outcome of the workshop was to identify whether or not any analytical gaps exist between the NC 12 vulnerability analysis and shoreline erosion forecast conducted for the project (described in Section 3.6.3.1) compared to recent and relevant research on global climate change. The workshop included presentations on the following: the overall project; the technical report *Bonner Bridge Replacement – Parallel Bridge Corridor with NC 12 Maintenance – Shoreline Change and Stabilization Analysis* (Overton and Fisher, June 2005); relevant vulnerability studies for NC 12; and potential impacts of climate change for both the entire US Transportation System and the specific project area.

The analysis conducted for the project in the technical report *Bonner Bridge Replacement – Parallel Bridge Corridor with NC 12 Maintenance – Shoreline Change and Stabilization Analysis* (Overton and Fisher, June 2005) and described in Section 3.6.3.1 predicts future changes in the shoreline based on the historical record. Panelists generally agreed that the analysis's high erosion results of

shoreline position may account for a portion of sea level rise caused by future changes in climate. In addition to this analysis, past sea level rise in one location and a range of potential future sea level rise scenarios for the mid-Atlantic coast were also considered. There was consensus that the current global sea level rise analytical models are not fully developed to predict local effects. The wide range of future sea level rise information considered illustrates the uncertainty associated with estimating future sea levels and shoreline locations. Panelists generally agreed that the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) with the island monitoring program outlined in Section 2.10.2.5 is the most practical method for carrying out the project with the given constraints, in part because it provides the opportunity to review and incorporate new analysis prior to commencement of each phase.

The Pamlico Sound Bridge Corridor would bypass the northern part of Hatteras Island and would likely be unaffected by accelerated shoreline erosion or breaches resulting from accelerated sea level rise. However, if Hatteras Island were to be fragmented, the existing hydrodynamics in Pamlico Sound could change, including the location of the natural navigation channel.

Accelerated sea level rise under scenario 2 would affect the Parallel Bridge Corridor alternatives as follows:

- With Nourishment. Increased demand for nourishment material (larger and/or more frequent projects). Erosion rates could increase such that beach nourishment would be practicably ineffective.

- With Road North/Bridge South. Possible shorter design life in the roadway section if the shoreline erodes faster than the project's high erosion forecast. The bridge component would bridge two of the three potential island breach areas.

- With All Bridge. It is possible that the bridges expected to remain over land would be in the ocean prior to 2060 if the shoreline migrates faster than the project's high erosion forecast. All five potential breach locations would be bridged.

- With Phased Approach/Rodanthe Bridge (Preferred). The uncertainties in determining exact location and timing of shoreline change would be addressed by designing an appropriate monitoring plan, as described in Section 2.10.2.5. This alternative would bridge the five potential breach locations. Four of the five potential breach locations would be bridged in Phase II and the fifth would be bridged in Phase III. So while the shoreline predictions do not incorporate the increase in sea level rise used in scenario 2, the overall approach of the Phased Approach/Rodanthe Bridge Alternative (Preferred) plans for conditions that will occur under scenario 2.

- With Phased Approach/Rodanthe Nourishment. The effects of the Phased Approach/Rodanthe Bridge Alternative (Preferred) are still applicable, except in the nourishment area, where the effects would be similar to the Nourishment Alternative. This alternative would bridge three of the five potential breach locations, but would not bridge the location in the Rodanthe area where a breach is considered most likely to occur.

If scenario 3 occurs, it could be argued that the processes reflected in the shoreline change rates used in project planning will change substantially, and past shoreline trends cannot predict future behavior. Since future monitoring is planned with the Phased Approach/Rodanthe Bridge Alternative (Preferred), one outcome of the monitoring could be to assess the predictions and develop new indicators as new information allows. The monitoring plan associated with the

Phased Approach/Rodanthe Bridge Alternative (Preferred) would provide important information since data collection would be in the projected period of accelerated sea level rise. Indicators of change could potentially be developed from the monitoring information and be used to modify Phase II-IV and allow adaptation in the design to accommodate the new information. Both the extent of bridging and timing could need to be modified. Monitoring of areas currently considered stable would be necessary because of the potential for changing processes.

Worst-case imagined scenarios, such as scenario 3 described in Section 3.6.3.3, suggest substantial island disintegration with substantial change in the hydrodynamics (the hydraulic exchange) between sound and ocean. Thus, it is important to keep in mind that this dramatic change in trends would affect not just the project area but the entire barrier island system.

4.6.7 Island Breach in the Pea Island National Wildlife Refuge

As indicated in Section 3.6.3.4, the potential exists in five locations for a breach to occur in Hatteras Island as a result of a storm between now and 2060 (though only the Rodanthe breach is likely). The word "breach" is used in this discussion rather than the word "inlet" because if a breach were to occur, it would likely close eventually (although not necessarily immediately) and likely would not become a long-term phenomenon like Oregon Inlet.

4.6.7.1 Island Breach at Site 3

Based on the opinions of the expert panel described in Section 3.6.3.2, the location most likely for a breach to occur would be at the southern end of the Refuge just north of Rodanthe (Site 3 shown on Figure E-1 in Appendix E). A breach at this location would not be of concern with the Pamlico Sound Bridge Corridor because the area would be bypassed by the bridge. Though the potential for such a breach would have to be taken into account in bridge location and foundation design, a breach at this location also would not be a concern with the Road North/Bridge South and All Bridge alternatives with the Parallel Bridge Corridor. The Rodanthe area bridge associated with these alternatives would span the potential breach location. The nourishment program associated with the Parallel Bridge Corridor with Nourishment Alternative would reduce the risk of a breach occurring, but it still would remain a possibility. The Phased Approach/Rodanthe Bridge Alternative (Preferred) also would bridge Site 3. The Phased Approach/Rodanthe Nourishment Alternative would bridge approximately 65 percent of Site 3, while nourishment would occur within the remaining 35 percent. Again, nourishment would reduce the risk of a breach occurring. However, the design of the nourishment program for the Phased Approach/Rodanthe Nourishment Alternative is not intended to provide protection throughout the potential breach location; thus breaching remains a possibility with this alternative.

With the Parallel Bridge Corridor with Nourishment or Phased Approach/Rodanthe Nourishment alternative, it is assumed the State of North Carolina would close a breach in the Rodanthe area to maintain the continuity of NC 12. Using the experience of closing the breach that formed just north of Hatteras Village near the southern end of Hatteras Island in 2003, it is estimated that between 400,000 and 500,000 cubic yards (306,000 and 382,000 cubic meters) of sand would be required to close a breach at the Rodanthe site. This estimate was not based upon specific dimensions for this potential breach, but rather it was based on the assumption that the breach would be similar to, but somewhat larger than, the Hatteras Village breach. A breach also could be bridged.

The expert panel considered two potential borrow areas for the sand to close a breach at the south end of the Refuge: offshore of Rodanthe and the outer bar at Oregon Inlet. Information available related to the ocean bar indicates that sand from that location is likely to be acceptable in terms of

its characteristics and volume to use to close a breach. The borrow site offshore of Rodanthe needs additional field work, including sediment cores, to confirm there is sand of acceptable characteristics and volume to be used to close a breach.

Based upon the 2003 experience at the Hatteras Village breach, the expert panel agreed that $10.00 per cubic yard ($7.60 per cubic meter) is a reasonable estimate for sand taken from the offshore borrow site at Rodanthe. For sand taken from the outer bar, because of the longer pumping distance, $15.00 per cubic yard ($11.50 per cubic meter) was the suggested unit cost estimate. Assuming 500,000 cubic yards (382,000 cubic meters) to fill a breach, an additional 30 percent of over fill (150,000 cubic yards [115,000 cubic meters]) because of multiple uncertainties, design and environmental assessment costs of $500,000, and an additional four percent for construction supervision, the total cost for closing a breach is estimated to range between:

- $7.28 million if the sand comes from the offshore site at Rodanthe, and

- $10.66 million if the sand comes from the ocean bar near Oregon Inlet.

The Hatteras Village breach was closed in approximately 60 days. This short time was in large part because of the declared emergency status of the project. While the expert panel agreed that a breach at Rodanthe would also be an emergency, the generally higher wave climate and the logistics of moving sand from either of the two potential borrow sites could result in a longer time to achieve closure. The expert panel considered two scenarios: 1) where no prior work had been done before the breach opened, and 2) where most of the design, permitting, and borrow material determination had been done in advance.

For the first scenario, where there was no advance preparation, the expert panel concluded that it might take as long as six months to close the breach. Several factors account for this longer time than for the Hatteras Village breach. Both the offshore borrow site and the inlet borrow site would be logistically more difficult to use than the borrow site at Hatteras Village. The dredges (probably two hopper dredges) would be working in the ocean (as opposed to Pamlico Sound), and weather delays would be likely. If the inlet borrow site were used, one or perhaps two booster pumps would be needed to move the material the approximately 12-mile (19.3-kilometer) distance to the breach. Substantial fieldwork would be required to map the borrow site and identify an adequate quantity of compatible material. Again, this fieldwork would take place at an offshore location during tropical storm season. Because the breach would be in the Refuge, additional environmental issues would potentially cause delays. All of these factors, plus other unforeseen problems, would probably lead to the longer time required to close the breach.

For the second scenario, with most of the preparation done in advance, the expert panel estimated that it would take up to three months to close the breach. This 90-day estimate is still a month longer than the recent experience at Hatteras Village. This is largely due to the expert panel's concern about the additional difficulties of using either an inlet source or an offshore borrow site, as well as the higher wave and storm exposure for this portion of the Outer Banks.

The expert panel suggested that advanced data gathering for the closure of a breach at the southern end of the Refuge would be prudent. This would be the case both in the near-term, until the proposed replacement project could be completed, or as a part of long-term planning if the Parallel Bridge Corridor with Nourishment or Phased Approach/Rodanthe Nourishment Alternative were implemented. Such advanced data gathering also should include the source of funding and a decision on whether the work should simply close the breach or use a wider configuration. The post-closure island cross-section (width) at the Hatteras Village breach is

smaller than the island cross-section prior to Hurricane Isabel. Thus, the Hatteras site is more vulnerable now than it was prior to the breach. This smaller cross-section is in part related to the source of funding to close the breach. A substantial portion of the cost for closing the breach was covered by the FHWA, which included limits that precluded building up the cross-section of the island to make it less vulnerable.

4.6.7.2 Island Breaches at Sites 1, 2, and 4

The potential for a breach to occur at these three locations between now and 2060 is considered minimal (see Section 3.6.3.4), with the potential being somewhat greater south of the Refuge's ponds at the location of the former New Inlet. The Pamlico Sound Bridge Corridor would bypass all of these sites. The Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) and with All Bridge Alternative would also bridge these sites. The Parallel Bridge Corridor with Road North/Bridge South Alternative would bridge only Site 1. The nourishment program associated with the Parallel Bridge Corridor with Nourishment Alternative would reduce the risk of a breach occurring, but it still would remain a possibility.

4.6.7.3 Island Breach at Site 5

Section 3.6.3.4 contains information related to the potential for a breach to occur near Oregon Inlet (potential breach Site 5). It describes the potential effect of soundside shoreline erosion, the presence of the Davis Slough channel behind Hatteras Island, and oceanside accretion. It is stated that a breach at Site 5 that isolates the terminal groin could cause substantial changes in the geomorphology (development of the land forms) around Oregon Inlet. It is assumed for this study that no mitigating activity will occur to prevent continued "inner bank" erosion. Therefore, the potential for soundside erosion to contribute to the formation of an inlet near the terminal groin that is deeper and more permanent than might occur elsewhere in the project area was taken into consideration during the development of the two Phased Approach alternatives (including the Preferred Alternative) by assuming larger and deeper bridge piles. This approach also could be taken with the Parallel Bridge Corridor with All Bridge Alternative. The discussion of the Site 5 breach relates to the various bridge alternatives evaluated in this FEIS in the following ways:

- Pamlico Sound Bridge Corridor. This corridor would bypass the north end of Hatteras Island; therefore, a breach near Oregon Inlet would not affect the bridge.

- Parallel Bridge Corridor with Nourishment Alternative. As noted in Section 3.6.3.4, nourishment reduces the vulnerability of this location to a breach because of ocean overwash. However, nourishment would not mitigate the risk from soundside erosion. If a breach were to occur, even though the likelihood is minimal, NC 12 would be severed with this alternative. In addition, as noted in Section 3.6.3.4, a breach that completely isolates the terminal groin would be difficult to fill with sand and keep closed. The Oregon Inlet bridge would need to be extended in order to keep NC 12 open.

- Parallel Bridge Corridor with Road North/Bridge South Alternative. Like the Nourishment Alternative, this alternative would involve maintaining a road at the north end of Hatteras Island. Thus, the outcome of a breach for this alternative, however minimal the risk, would be similar to the Nourishment Alternative. The additional reduction in the potential for a breach offered by nourishment to reduce the vulnerability of this location to a breach would not occur with this alternative because the Road North/Bridge South Alternative includes no nourishment or dune maintenance.

- Parallel Bridge Corridor with All Bridge Alternative. This alternative would generally bridge the potential breach location at the north end of Hatteras Island. The design assumptions for the alternative presented in this FEIS would have two limitations in terms of the impact of a breach. First, the foundation assumptions included in the cost estimates for this alternative are lighter and shallower than those for the Phased Approach alternatives (including the Preferred Alternative), since they presume that the bridge would cross land and not be subjected to a breach, particularly one that would be deep and permanent as it competes hydraulically with Oregon Inlet. The same foundation currently assumed for the Phased Approach alternatives (including the Preferred Alternative), however, could be assumed for this alternative at additional cost. Second, this alternative assumes that access to the Refuge at the north end of Hatteras Island would be via a surface road. Such a road could be affected by a breach, however minimal the risk, with the same effects as described for the Nourishment Alternative. Again, the same access strategy assumed for the Phased Approach alternatives (including the Preferred Alternative) (i.e., bridge with ramps to the ground) could be assumed for this alternative at additional cost.

- Parallel Bridge Corridor with Phased Approach Alternatives (including the Preferred Alternative). This alternative would be the best suited to accommodate a breach at the north end of Hatteras Island, in that larger and deeper bridge foundations are presumed and the potential breach location would be fully bridged. Thus, in terms of the Parallel Bridge Corridor alternatives, this alternative would be best suited to accommodate a breach, however minimal the risk, should one occur at the north end of Hatteras Island. This alternative would not, however, be at navigation height. Thus, if Davis Slough became the more-preferred flow pattern between the ocean and Pamlico Sound, as it could if the terminal groin were removed (see Section 3.6.3.5 under "Long-Term Impacts of the Removal of the Terminal Groin"), dredging the Oregon Inlet channel could become more challenging since the dredged channel would have to remain in Oregon Inlet. The channel could not be moved to a location south of the terminal groin because of the presence of the bridge.

Physical modeling of the hydraulics of the Oregon Inlet area could provide additional insight into the degree to which waves and/or current control the erosion processes and the risk of inlet formation. Modeling also would be useful in developing mechanisms for mitigating that risk, particularly as it relates to the design of the bridges associated with the All Bridge and Phased Approach alternatives (including the Preferred Alternative). Such modeling would be conducted as a part of design development for the Phased Approach/Rodanthe Bridge Alternative (Preferred), as discussed in Section 2.10.1.2 under "Wave Energy, Storm Surge, and Scour."

4.6.8 Off-Shore Coastal Processes with the Phased Approach Alternatives

The two Phased Approach alternatives (including the Preferred Alternative) add several additional considerations related to coastal processes that are addressed in this section. They relate to the effect of bridge piles in the ocean on scour, longshore sediment transport, wave climate, beach erosion, breach formation, and short-term NC 12 maintenance needs until Phases II to IV are implemented.

The coastal zone potentially affected by the two Phased Approach alternatives (including the Preferred Alternative) is generally depicted as being made up of four distinct regions. Using nomenclature defined in the USACE *Coastal Engineering Manual*, (USACE, 2002) these zones are referred to as upland, shore, shoreface, and offshore. The upland zone is landward of the toe

of the dune, inclusive of the dune. The shore extends from the mean low water (MLW) to the upper extent of storm damage (toe of the dune) and is divided into the backshore and the foreshore. The backshore is from the MHW to the toe of the dune and the foreshore is between the MHW and MLW. The shoreface extends from MLW to the flattened slope seaward of the offshore (sand) bar and is referred to as the nearshore. The offshore is seaward of the nearshore.

The upland area includes the dune field. The dune (in the absence of human intervention) is built, enlarged, or altered by wind-blown sand transport. Onshore winds provide the fuel for transport, and a wide dry beach supplies the source. The presence of obstructions to the wind (vegetation, topographic change, man made structures) lowers the wind energy available for transport and "traps the sand," resulting in the formation, growth, and migration of sand dunes. The upland area also is affected by larger storms in which water overwash of the dune field occurs. The characteristics of sediment (e.g., sand) transport during these events is a function of the hydraulics (water movement) of the event. Sediment can be transported landward, creating overwash fans of sediment. If however, the water level on the Pamlico Sound side is elevated, the flow of water from the soundside to the ocean side can sweep quantities of sand seaward. This latter phenomena is associated with inlet breaching.

The backshore, characterized as being landward of the MHW, is typically the dry beach. Therefore, the backshore also is subjected to wind blown transport. It is expected that the backshore loses sand to the dune when onshore winds dry the beach and move sand landward. In addition, the backshore is affected by wave action during high water events or storms. Sand can either be transported onto the backshore or eroded from the backshore, depending on the wave characteristics. The upward limit of transport is related to the wave run-up limit, that is, typically long period waves transport sand landward and short period waves erode the backshore.

The foreshore is subjected to the action of swash (water movement associated with waves and the tide) on a daily basis and thus substantial volumes of sand are transported onshore and offshore daily. Sediment is continually reworked and transport is dependent on the rising and falling of the tide and the wave conditions.

The nearshore zone extends from the “breaker zone” of the shore, through the surf zone and seaward of the offshore (sand) bar. Waves initially break over the offshore bar, reform, and break again just offshore of the MLW (breaker zone). This is a zone of high energy dissipation (because of wave breaking) and potentially a zone of substantial modification of the beach profile during storm events.

The offshore zone is assumed to be seaward of the wave breakers, and while transport can occur, much less modification of the profile is observed during storm events.

Nearshore currents act to transport sand in the longshore direction, generally from north to south. Waves breaking obliquely (neither perpendicular nor parallel) to the shoreline create a momentum flux (change) that drives longshore currents. Wind also can contribute to the development of these currents. These currents flow parallel to the shore and are strongest in the surf zone, decaying substantially once seaward of the breakers.

4.6.8.1 Effect of Bridge Piles on Scour

The extent of scour in the ocean bottom associated with the bridges built as a part of Phases II to IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred) would be dependent on:

- The length of bridge in the ocean by year;
- Whether or not bridge is in or out of the area where the ocean waves break (breaker area); and
- The size and proximity of the individual piles that make up the bridge's foundation.

The portions of Phased Approach/Rodanthe Bridge Alternative (Preferred) in the ocean would create a total scour area on the ocean bottom as large as approximately 15.6 acres (6.3 hectares) by 2060. The displaced volume of sand in 2060 would be as large as approximately 152,678 cubic yards (116,714 cubic meters). The following paragraphs describe how these findings were reached.

Length of Bridge in Ocean (Phases II to IV)

Assuming both the high erosion shoreline (shown in Figure E-1 of Appendix E) modeled for the development and assessment Bonner Bridge project alternatives and the estimated completion of Phase II in 2015, Phase III in 2020, and Phase IV in 2030, the length of the bridge in the ocean would be:

- 2020: 1.6 miles (2.6 kilometers);
- 2030: 2.8 miles (4.5 kilometers);
- 2040: 4.2 miles (6.8 kilometers);
- 2050: 5.2 miles (8.4 kilometers); and
- 2060: 5.9 miles (9.5 kilometers).

Breaker Area

Scour depth in breaking waves has been studied in the lab and observed in the field at two research piers (USACE Field Research Facility at Duck, North Carolina and by Bayram and Laursen using data from a research pier in Japan). These studies found that, in the breaker area, scour occurred around piles, but that the high turbulence produced by breaking waves and the subsequent large volumes of sediment transport acted to fill in these holes landward of the breaking point. Thus, scour holes are expected to occur in association with Phases II to IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred) only once they are seaward of the wave breaking point. Landward of the breaker, the piles could alter the development of a "barred" profile and contribute to the formation of rip currents, features that occur naturally along the coast but have been noted occurring in relationship to piers.

To determine the depth at which the waves break (depth of breaking), two conditions were investigated: 1) the yearly average conditions (average of the depth at breaking for January through December) and 2) the average depth of breaking during the primary fish transport season (February through May). These depths were applied to offshore profiles taken in 2004 at 89 locations in the project area. For each station, the distance from mean high water (the shoreline) to the depth of breaking was determined. In the case of an offshore (sand) bar that was higher than the depth of breaking, the depth of breaking on the seaward side of the bar was taken. In these locations, waves will likely reform and break again closer to shore. In general the distance to the breaking depth from the shoreline is greater in the northern part of the project area (450 to 500 feet or 137 to 152 meters). These distances decrease to 200 to 300 feet (61 to 91 meters)

further south with the exception of the hot spot in the Rodanthe area. The distance offshore in the Rodanthe area is controlled by the steep foreshore and the presence of an offshore bar.

In addition, the zone of impact of the wave generated longshore current was delineated relative to the depth of breaking. The longshore current is a function of the breaking wave height and the wave breaker angle to the shore. The distance to breaking described in the paragraph above was multiplied by 2 as a conservative estimate of this type of influence.

An overlay of the position of Phases II to IV, projected high erosion shoreline positions, and the width of the breaker zone resulted in the characterization of the project in relation to the breaker zone shown in Table 4-10 from 2020 to 2060.

Table 4-10. Bridge Length Inside and Outside the Breaker by Year

Location	Phase	in feet (meters)									
		2020		2030		2040		2050		2060

New Inlet/South Ponds	III/IV										
Visitor Center	II									2,316	(706)
North Ponds	IV										
Canal Zone and Sandbag Hot Spots	II							741	(226)	1,860	(567)
TOTAL				2,874	(876)	5,230	(1,595)	7,532	(2,296)	13,647	(4,161)

Note: Where two numbers are shown in a single location, it indicates that two separate bridge segments are in the water inside the breaker area.

Pier Assumptions

The scour analysis assumed that the pier configuration in the Sandbag and Canal Zone hot spot areas (beginning approximately at the north end of the Refuge's ponds and included in Phase II) would consist of eight piles each arranged in a 2x4 configuration. The piles were assumed to be 54-inch (137-centimeter) cylinder piles (circular cross-sections). The piles for each pier would be placed within a 21-foot x 48-foot (6.4-meter to 14.6-meter) area. For the rest of the project, four pier configurations were considered:

1. Eight piles each arranged in a 2x4 configuration using 30-inch (76.2 centimeter) square piles in an area 15 feet x 48 feet (4.6 meters x 14.6 meters);

2. Three groups of four 20-inch (50.8 centimeter) square piles arranged in a 2x8 configuration in an area 10 feet x 36 feet (3.0 meters x 11.0 meters);

3. Four 6-foot (1.8-meter) cylindrical piles arranged in a linear (1x4) configuration in an area 10 feet x 36 feet (3.0 meters x 11.0 meters); and

4. Eight 4-foot (1.2-meter) cylindrical piles arranged in a 2x4 configuration in an area 10 feet x 36 feet (3.0 meters x 11.0 meters).

The configuration at the northern end of Hatteras Island and the configuration for the rest of the project reflect the representative description of the Phased Approach/Rodanthe Bridge Alternative (Preferred) presented in Section 2.10.2.4. Alternate configurations are considered to determine if scour holes would be substantially different in area with different configurations. It was assumed that the material scoured was sand.

Scour Analysis

When a vertical cylinder (pile) is placed in a uniform flow field (waves and current), the flow will be modified as the water and the pile interact, which can result in scour of the ocean bottom. The scour analysis looked at the potential depth and area of scour around both individual piles in a pier and the groups of piles that make up the pier.

Scour depths were calculated in three locations along Phase II to IV: the Canal Zone Hot Spot area (north end of the project on Hatteras Island), the Refuge Visitor Center area (middle of the project area), and in the 'S' Curves Hot Spot area (south end of the project area). Three locations were examined to determine if scour depths would substantially vary across the project area. Scour also was calculated by month to determine if there was substantial seasonal variation. The scour depths in each case were similar.

The seasonal range of individual pile scour depth for the three locations is:

- 'S' Curves: 3.9 to 4.3 feet (1.2 to 1.3 meters);

- Visitor Center: 4.1 to 4.7 feet (1.2 to 1.4 meters); and

- Canal Zone: 3.9 to 5.0 feet (1.2 to 1.5 meters).

The deepest holes all occurred in September.

Increased scour around an entire group of piles has been observed to be a general lowering of the bed around the group to depths greater than for individual piles. This group scour is a function of the increase in velocity between the piles within the gap and the turbulence generated by the piles. When analyzing scour depths of groups, seasonal depth ranges found were:

- 'S' Curves: 7.3 to 8.7 feet (2.2 to 2.7 meters);

- Visitor Center: 8.2 to 9.4 feet (2.5 to 2.9 meters); and

- Canal Zone: 7.9 to 9.9 feet (2.4 to 3.0 meters).

Again, the deepest holes all occurred in September. Given that group scour results in greater depth of scour, the rest of the scour analysis focused on group scour.

The area affected by group scour was determined for two scenarios. In the first, the long side of the area scoured is aligned in the long shore direction (roughly parallel with the project). Under this scenario, the group scour associated with one pier (group of piles) would overlap with the next with an assumed pier spacing of 120 feet. In the second scenario, it was assumed that the area scoured was not aligned such that the group scour holes overlap. Scenario two would result in the larger area of effect. Volume is computed for the non-overlapping case so that the maximum impact for each pier assumption is reported.

Results

For the foundations south of the Canal Zone Hot Spot, Foundation Alternatives 1 and 2 above would result in the maximum and minimum scour holes impact, respectively, of the four alternative pile designs considered. Scour area and volume estimates for these alternatives and the Canal Zone area foundation are presented in Table 4-11 and Table 4-12, respectively.

The smaller pile size (20 inches [50.8 centimeters]) and smaller footprint (10 feet x 36 feet [3.0 meters x 11.0 meters]) of Foundation Alternative 2 would yield the smallest scour areas, as would be expected for the smallest pile size and smaller footprint area.

Table 4-11. Area Affected by Scour by Location and Year[1]

	Canal Zone Hot Spot in acres (hectares)		Visitor Center Area in acres (hectares)		'S' Curves Hot Spot in acres (hectares)	
	Overlap	No Overlap	Overlap	No Overlap	Overlap	No Overlap
			Visitor Center/'S' Foundation Alternative 1			
2030	0.0	0.0	0.0	0.0	4.1 (1.7)	4.6 (1.9)
2040	0.0	0.0	0.0	0.0	7.6 (3.1)	8.6 (3.5)
2050	1.3 (0.5)	1.5 (0.6)	0.0	0.0	9.9 (4.0)	11.2 (4.5)
2060	3.1 (1.3)	3.8 (1.5)	3.6 (1.5)	4.3 (1.7)	13.8 (5.6)	15.6 (6.3)
			Visitor Center/'S' Foundation Alternative 2			
2030	0.0	0.0	0.0	0.0	3.1 (1.3)	3.1 (1.3)
2040	0.0	0.0	0.0	0.0	5.7 (2.3)	5.9 (2.4)
2050	1.3 (0.5)	1.5 (0.6)	0.0	0.0	7.5 (3.0)	7.6 (3.1)
2060	3.1 (1.3)	3.8 (1.5)	2.7 (1.1)	2.8 (1.1)	10.4 (4.2)	10.6 (4.3)

[1] The area affected by group scour was determined for two scenarios. In the first, the long side of the area scoured is aligned in the long shore direction (roughly parallel with the project). Under this scenario, the group scour associated with one pier (group of piles) would overlap with the next with an assumed pier spacing of 120 feet (36.6 meters). In the second scenario, it was assumed that the area scoured was not aligned such that the group scour holes overlap. Scenario two would result in the larger area of effect.

Table 4-12. Volumes of Sand Displaced by Scour

	in cubic yards (cubic meters)			
	Canal Zone Hot Spot	Visitor Center Area	'S' Curves Hot Spot	Total
		Visitor Center/'S' Foundation Alternative 1		
2030	0.0	0.0	29,083 (22,236)	29,083 (22,236)
2040	0.0	0.0	54,372 (41,570)	54,372 (41,570)
2050	10,126 (7,742)	0.0	70,810 (54,138)	80,937 (61,881)
2060	25,315 (19,355)	28,733 (21,968)	98,629 (75,407)	152,678 (116,731)
		Visitor Center/'S' Foundation Alternative 2		
2030	0.0	0.0	16,862 (12,892)	16,862 (12,892)
2040	0.0	0.0	31,525 (24,103)	31,525 (24,103)
2050	10,126 (7,741)	0.0	41,055 (31,389)	51,182 (39,131)
2060	25,315 (19,355)	15,618 (11,941)	57,184 (43,720)	98,118 (75,017)

The volume of sand displaced in the areas is approximated based on the assumed geometry of the hole and is shown in Table 4-12. The higher no overlap acres are assumed. The total volume of sand displaced by scour by 2060 would be between 100,000 cubic yards (76,455 cubic meters) and 153, 000 cubic yards (116,977 cubic meters). This is roughly 50 to 75 percent of the 200,000 cubic yards (159,911 cubic meters) of sand that NCDOT plans to remove from the terminal groin fillet in 2008 to replenish the beach berm in the 'S' Curves Hot Spot area. The net littoral sand transport to the south around Oregon Inlet is estimated to be about 862,000 cubic yards (659,046 cubic meters) per year.

The area that is projected to have the largest areal extent of scour holes is the 'S' Curves Hot Spot. The holes could develop earlier in the timeline of the project because of the steep offshore slopes in this area. Because more pile groups would be affected, more total area (and volume) would be removed. The volume removed would stay within the littoral system, initially deposited downdrift of the piles, and then subjected to the local background cross shore and/or longshore sediment transport patterns. The holes would shift in size and shape with change in wave height and direction and could contribute to localized changes in the nearshore wave characteristics given the alongshore length expected to be affected. Perhaps more important, however, to the projection of impacts to coastal processes for the 'S' Curves Hot Spot is that this is the area determined to have the highest "breach" potential (see Section 3.6.3.4).

In the event of a breach, the hydrodynamics and sediment transport in and around the pilings would be dominated by inlet processes (not wave and longshore currents) and the scour holes that would develop would be in the inlet throat, not offshore. The dynamics of scour would be similar to that found in inlets (for example, Oregon Inlet), but the magnitude of the scour holes would depend on the characteristics of the new inlet (i.e., width, depth, volume of flow, and sediment size), as well as the bridge pier design. The characteristics of the scour in the new inlet should be

similar to that found in inlets of comparable flow velocity, sediment characteristics, and bridge pier design. However, because of the uncertainty of the characteristics of a potential new breach (see Section 3.6.3.4), this potential scour is not determined.

4.6.8.2 Effect of Bridge Piles on Wave Climate

Wave climate is generally defined as the long-term statistical characterization of waves in the ocean. The presence of the bridge piles is not expected to change the wave climate seaward of the bridge pile vicinity.

The potential for the bridge piles to impact the wave climate in the vicinity of the bridge piles and landward is first delineated by considering the pile diameter to wavelength ratio. Large pile diameters combined with short wavelengths have the greatest potential for wider spread wave impacts. For the Phased Approach alternatives (including the Preferred Alternative), the diameter to wavelength ratio is such that the flow would be in the slender-pile regime. This indicates that the presence of the piles (as an object that blocks the flow) should not substantially influence the wave form other than in the immediate vicinity of the pile group (Sumner and Fresoe, 2002).

In addition to the presence of the piles, the wave/structure/sediment interaction contributes to the change in the bathymetry (bottom topography) in and around the pile groups in the form of scour. This change in bottom topography could result in wave refraction (bending), wave reflection, local wave diffraction (bending around an object), and wave dissipation in the vicinity of a scour hole. This impact would be greatest when the piles are seaward of the breaking zone (where scour holes develop). Changes in the wave form from these effects also could affect the longshore currents since longshore current is a function of wave height and wave direction.

Finally, the presence of piles has the potential to interrupt the development of an offshore bar (see Section 4.6.8.1). The lack of development of the bar could cause relative changes in the alongshore wave height by changing the location of the breaking. This change could contribute to the formation of rip currents, a feature that occurs naturally along the coast but has been noted occurring in relationship to piers. The presence of the piles (and subsequent break in the bar) could serve to fix the location of a rip current under and aligned seaward with the bridge pier, but should not increase the frequency of occurrence since rip currents also are a function of the wave and tide conditions.

4.6.8.3 Effect of Bridge Piles on Longshore Sediment Transport

The local scour impact described in Section 4.6.8.1 could extend to a more global impact on the coastal processes if the structure were to interfere with either the longshore (north to south) transport of sediment or the cross-shore transport associated with storms. Although the scour holes would dominate in the vicinity of bridge piles, the USACE Field Research Facility (FRF) data shows no net loss of beach downdrift of its pier that would be suggestive of the trapping of sand that can be associated with structures perpendicular to the shore. The spacing of the pier's piles is such that the longshore sediment transport is not globally affected by the local scour that occurs. The cross-shore transport associated with storm events is dependent on the local bathymetry of the beach face; thus the scour holes necessarily change the cross-shore wave dynamics and sediment transport. The FRF data from the research pier does not suggest that the pier's piles have a substantial impact on the cross-shore transport. The upland areas at the FRF's pier, however, have higher elevations than those on Hatteras Island and have not experienced the repeated dune erosion and overwash that is common in the project area.

The FRF configuration resembles the case of a single pile group, but does not model the impact of a series of scour holes in the alongshore direction. In general, longshore sediment transport is a function of the breaking wave height and breaking wave angle. The length of shoreline along which these wave characteristics are changed because of the presence of the scour hole is a factor in the assessment of impact. Thus, the development of scour holes described in Section 4.6.8.1, as well as the subsequent effect on the local wave characteristics described in Section 4.6.8.2, could potentially have an impact on the localized longshore sediment transport and resulting erosion and accretion patterns along the shoreline, depending on the size and orientation of the holes.

4.6.8.4 Effect of Bridge Piles on Beach Erosion

Wave transformation over scour holes (see Section 4.6.8.1) would likely cause refraction of the incoming wave creating a persistent non-uniform wave climate on the beach. The degree of refraction would be a function of the scour depth and size and orientation of the holes. By bending the waves around the holes, energy would be focused in different patterns than without the presence of the holes. This could preferentially redistribute sediment creating erosional hot spots/troughs (or cold spots/crests), (Kraus and Galgano, 2001). If the effect is strong enough, it could result in a highly cuspate (scallop-like) beach, with the troughs being locations of erosion and crests the relative lack of erosion or accretion. The spatially alternate troughs and crests would be associated with the location of the scour holes, developing a rhythmic pattern of erosion and accretion along the shoreline.

The break in the offshore bar described in Section 4.6.8.2 would allow waves to move closer to shore before breaking. Once through the gap, waves would diffract (bending back toward the bar) creating complex flow patterns landward of the bar. Erosional hot spots could develop directly landward of the gap from the resulting larger wave heights that would propagate through the gaps (Kraus and Galgano, 2001).

Rips are observed to form in gaps in the bar (either in association with a structure such as a pier or without). Rips are strong shore perpendicular currents in the seaward direction and thus have the potential to transport sediment seaward. Erosional hot spots in association with rips locally narrow the beach. If the beach becomes too narrow, the rips also can be associated with dune erosion (Thorton et al., 2007).

Cusps, rips and breaks in the bar are all naturally occurring features along Hatteras Island today. The impacts on beach erosion as noted are already part of the system. However, the formation of these features associated with fixed locations (e.g., the piles) could create persistent features that would lead to focused erosional hot spots that are not currently present in the system.

4.6.8.5 Effect of Bridge Piles on the Potential for an Island Breach During Storm Events

In the foreshore, backshore and upland zones the impact on cross-shore sediment transport because of the Phased Approach alternatives' (including the Preferred Alternative) piles generally would be during storm events. Two impacts can be anticipated. Scour around the bridge supports is expected during events that bring the water level in contact with the bridge. The scour hole that would develop should be a function of water level, current, and wave action, as well as the duration of the storm. In the case of an overwash event in which sand is transported landward, scour holes would develop but sediment transport should not be substantially interrupted and a washover fan should develop. During an event in which flow is reversed from sound to ocean because of elevated water levels in Pamlico Sound, there could be more erosion because of the presence of the bridge supports. The combination of scour around the piles and the channeling of the flow in the cross shore direction would increase the erosion potential. Since

these events are associated with the creation of a breach in the island, it is possible that the presence of the structure could accelerate the development of a breach during these events.

During non-storm conditions, the bridge elements in the upland area could increase sediment accumulation because of the interruption of the windblown transport processes. In the backshore, the interruption of windblown sediments could cause a loss of transport from the beach to the dune.

4.6.8.6 Short-Term NC 12 Maintenance Needs until Phases II, III, and IV are Implemented

This section identifies, based on past experience, potential short-term maintenance activities that likely would occur prior to implementation of Phases II, III, and IV with the Phased Approach alternatives (including the Preferred Alternative). One difference from past experience is that the Refuge has concluded that the selection of the Phased Approach/ Rodanthe Bridge Alternative (Preferred) as the project for implementation in a Record of Decision (ROD) will preclude future storm-related maintenance outside of the NC 12 easement from being found compatible with the Refuge under the requirements of National Wildlife Refuge System Improvement Act of 1997. Thus, after the issuance of the ROD for this project, NCDOT would confine future NC 12 maintenance in the Refuge, including storm-related maintenance, to the existing NC 12 easement. Maintenance prior to the completion of Phase I is not addressed because it would occur with all of the alternatives (Pamlico Sound Bridge Corridor and Parallel Bridge Corridor) and, thus, it is not a factor in the decision-making process.

Based on past experience, there are five characteristic types of maintenance needed to keep NC 12 clear and open to traffic. These activities occur on Hatteras Island. Such activities do not occur, nor are expected to occur, on Bodie Island in the project area. The five activities are listed and defined in Table 4-13.

Activity 1 (road scraping) can occur as part of routine maintenance whenever wind blown sands are deposited on NC 12 to such a degree that mechanical removal is necessary. Activities 2 (dune maintenance), 3 (dune rebuilding), and 4 (sandbag-based dune and berm replenishment) are generally storm related activities. Factors which play into determining whether these activities occur or how often they occur at any given location on NC 12 increases with:

1. Decrease in the distance between NC 12 and shoreline;

2. Degradation of the dunes along the shoreline;

3. Magnitude of a storm event;

4. Frequency of storm event; and

5. Sediment supply.

In the past, activity 5 (dune translation) has occurred only in the Canal Zone Hot Spot area because of the large supply of windblown sand available from the terminal groin fillet and the wider beaches just north of the hot spot.

The existing dunes protect NC 12 from overwash. When the dune is lost either because of long-term erosion or storm events, NC 12 is more vulnerable to sand and water on the pavement. Under conditions dominated by long-term erosion, the beach width narrows, the ocean is closer to the toe (ocean side) of the dune, and daily waves and tides can erode the base of the dune until the dune face collapses providing sand to the beach. The beach may temporarily widen (providing

Table 4-13. Types of Past Storm-Related NC 12 Maintenance Activities and Frequency

Activity	Characteristics	General Past Frequency of Events Necessitating These Activities[1]
Minimal to none (MN)	Shoreline and dune characteristics expected to be adequate to keep sand off the road.	
1. Road Scraping	Pushing sand off the road on to the shoulders of the road and regrading swales (within the easement).	1 to 2 times per month
2. Dune Maintenance	Patching small holes or loss of elevation in the dune. Sand is typically moved from the shoulder on the seaward side and pushed up on the dune. In areas of existing vegetation, equipment with rubber tires is used to minimize damage if the vegetated site cannot be avoided entirely. Sand fencing may also be a minor repair or used in areas dune growth and dune stabilization is desired.[2]	2 to 3 times per year
3. Dune Rebuilding	Similar to 2 but at a larger scale. Sand from the landward shoulder of the easement (or other source on Hatteras Island) needed. Bulldozers are typically used to push sand up into a dune formation from the landward side of the dune. Minimal work is done from the seaward side. Efforts from the seaward side are intended to shape the dune. There is no beach scraping to obtain material to form the dune. Dune planting to attempt re-vegetation also may occur, as well as sand fencing to help stabilize the dune.[2]	1 to 2 times per year
4. Sandbag-Based Dune and Berm Replenishment	Because of the lack of beach width, the dune is rebuilt with a sandbag core. Sand is placed on the beach to rebuild a berm. This berm provides habitat that would be available in the absence of the dune, as well as provides protection for the dune. The sole example of this in the project area is the maintenance project planned for Rodanthe in 2008 in which approximately 200,000 cubic yards (152,911 cubic meters) of sand will be excavated from the terminal groin fillet and trucked hauled and placed in the Rodanthe 'S' Curves Hot Spot. Sand is placed as much as possible above the high water line and natural processes are allowed to rework the material. Placement below the high water line occurs when the distance from toe of the dune to the high water line is less than that distance needed to operate the necessary equipment.	Only one occurrence of this activity; it is currently (2007/2008) being completed at the southern end of the Refuge. Prior to 2015, the sandbag area will need to be lengthened up to about 1,500 feet (762 meters).
5. Dune Translation	When the large windblown dunes migrate onto the shoulder of NC 12, excavating equipment is used to "scoop" the sand from the backside of the dune and place the sand forward of the dune crest so that it replenishes the front slope of the dune. This currently only occurs in the Canal Zone Hot Spot.[2]	1 to 2 times per year

[1] Based on NCDOT storm frequency and maintenance activity experience in the three hot spots found within the Refuge.

[2] In the past, this activity has generally occurred partially or completely outside of the existing NC 12 easement.

distance), but the lowering of the maximum elevation of the dune leaves the road vulnerable to overwash in subsequent storms. During storm events in which the water level is elevated because of the storm surge (water elevated by storm winds) the dune can be systematically undermined or overtopped, creating a dune blowout, overwash, and washover fan.

Using distance to shoreline, apparent dune integrity, and past storm maintenance experience (keeping in mind that future maintenance would occur within the NC 12 easement), the susceptibility of the NC 12 area needing maintenance can be projected. In addition, NC 12 maintenance experience has revealed that when the dune heel (side of the dune facing the sound) gets within 10 feet (3 meters) of NC 12 and the dune is un-vegetated, windblown sand on the road is a common occurrence. This has occurred in the Canal Zone Hot Spot area. The wind blown sand also creates a problem with water on the pavement because of the storm creates high shoulders and swales filled with sand. The road becomes a low point for standing water.

Table 4-14 and Table 4-15 present forecast shoreline areas likely to require maintenance activities assuming the average and the high erosion shoreline findings, respectively, that were prepared as a part of this FEIS. Maintenance activities are assumed to cease as each portion of the Phased Approach/Rodanthe Bridge Alternative (Preferred) is completed.

The tables contain the following elements:

- Activities estimated under 2010, 2015, 2020, and 2030 shoreline conditions with the presumption that Phase II is completed shortly after 2015, Phase III is completed shortly after 2020, and Phase IV is completed shortly after 2030 (see Section 2.10.2.5);

- The length of NC 12 forecast to be likely to require each activity in each year; and

- The percent length of NC 12 within the Refuge that would require each activity in each year, including the length of NC 12 where the distance to the shoreline and dune integrity is expected to be great enough that none of the activities are expected to occur.

Given that maintenance would stay within the existing NC 12 easement, and the past activities presented in Table 4-13 can occur outside the easement, Table 4-14 and Table 4-15 assume the following three projected future activities:

1. Road Scraping. Same as defined in Table 4-13;

2. Dune Building and Maintenance in Easement. Since dunes that develop small holes or lose elevation as a result of a storm are generally outside of the NC 12 easement, they could no longer be repaired. Instead, a small dune would be built in the NC 12 easement to account for the weaker dune outside of the NC 12 easement. This activity could occur somewhere along NC 12 within the Refuge two to three times per year based on past experience with the development of small holes or loss of elevation in existing dunes. Maintenance of this dune also would occur once built. Once dunes are built, their maintenance or repair could occur at intervals more frequent than the manifestation of the original need since this activity would not restore the damaged original dune.

3. Sandbag Dune Building and Maintenance in Easement. In the past, dunes that have been substantially lost to a storm have been rebuilt. Because of the greater exposure to NC 12 resulting from the substantial loss of a segment of dune and because rebuilding would need to be confined to available space within the NC 12 easement, the dune would be rebuilt with a

Table 4-14. Forecast Areas in Refuge Susceptible to Three Projected Future Storm-Related NC 12 Maintenance Activities (Average Erosion Shoreline)

[1] The lengths reflect each location's susceptibility to the need for the storm-related maintenance activities indicated. The area actually affected by any given storm generally would be less than the lengths shown. Minor events tend to result in spotty activities and larger events tend to result in activities that affect larger portions of the susceptible locations. At locations susceptible to the more intensive activity 3, minor events are likely to cause more extensive 1 and 2 activities than at locations not susceptible to activity 3.

[1] The lengths reflect each location's susceptibility to the need for the storm-related maintenance activities indicated. The area actually affected by any given storm generally would be less than the lengths shown. Minor events tend to result in spotty activities and larger events tend to result in activities that affect larger portions of the susceptible locations. At locations susceptible to the more intensive activity 3, minor events are likely to cause more extensive 1 and 2 activities than at locations not susceptible to activity 3.

sandbag core. This activity could occur somewhere along NC 12 within the Refuge one to two times per year based on past experience with substantial dune loss. Maintenance of this dune also would occur once built. Once sandbag dunes are built, their maintenance or repair could occur at intervals more frequent than the manifestation of the original need since this activity would not restore the substantially lost original dune.

Items 2 and 3 in Table 4-13 could still be done if they could be done within the existing easement, but are not assumed in Table 4-14 and Table 4-15 because those solutions are generally applicable to repairs when the dunes are still outside or partially outside of the NC 12 easement. Item 4 could not be done as described in Table 4-13 because berm replenishment would occur outside of the NC 12 easement. Item 5 in Table 4-13 could not be done within the existing NC 12 easement.

The lengths shown in Table 4-14 and Table 4-15 reflect locations expected to require the storm-related maintenance activities indicated. The area actually affected by any given storm generally would be less than the lengths shown. Minor events tend to result in spotty activities, and larger events tend to result in activities that affect larger portions of the susceptible locations. At locations susceptible to the more intensive activity 3, minor events are likely to cause more extensive 1 and 2 activities than at locations not susceptible to activity 3.

Past activities and their frequencies presented in Table 4-13 were derived primarily from maintenance records dating from 1991. Maintenance requirements at the hot spots have increased substantially since 1999 with Hurricanes Dennis, Bonnie, and Floyd, and increased again with Hurricane Isabel in 2003. The projected three activities that likely would be used for maintenance in the future and their associated frequencies were developed from a post-1999 storm activity baseline. From 1999 to November 2007, there were six hurricanes, one tropical storm, and 13 nor'easters or other storms that required cleanup activities. Even larger, more frequent storms that directly affect Hatteras Island could alter the assessments of Table 4-14 and Table 4-15. Also, with this in mind, the category minimal to none carries two connotations: 1) the activity itself is minimal (infrequent occurrences of activity 1), or 2) there is a minimal probability of occurrence using the criteria just described.

Table 4-14 and Table 4-15 indicate that the level of NC 12 maintenance related to storms will continue in the three hot spots and likely increase in those areas until Phase II is completed. Again, NCDOT would confine this work to the existing NC 12 easement, since the Refuge has indicated that such work would not be found compatible with the Refuge under the requirements of the National Wildlife Refuge System Improvement Act of 1997. Recognizing the desirability of ending these activities, NCDOT intends to place a high priority on the implementation of Phase II, as discussed in Section 2.10.2.5. The completion of Phase II would substantially decrease the amount of storm-related maintenance on NC 12, but some would remain and would increase prior to the completion of Phases III and IV, but not to the extreme currently occurring in the three hot spots.

As indicated in Section 2.10.2.5 and in commitment number 15 of the Project Commitments section, NCDOT also would not perform storm-related NC 12 maintenance work outside of the existing easement in the Phase III, IV, and no action areas on NC 12 for the reason noted in the previous paragraph. Limiting the growth in the need for NC 12 storm-related maintenance in the Phase III and IV areas to the extent practicable given the availability of transportation funding and the efficient use of those funds also is considered desirable. In order to help accomplish that objective, NCDOT would implement a monitoring program, the particulars of which would be developed in consultation with representatives of the Refuge, including development of decision-making criteria for translating monitoring findings into a decision to move forward with an additional phase and how to refine the location of each phase to reflect actual future shoreline change.

4.7 Natural Systems

This section addresses each alternative's impacts to natural systems as they relate to: geology, topography, and soils; surface waters and water quality; biotic communities; wetlands and open water habitat; unique and rare habitats; fisheries and wildlife; protected species, and avoidance, minimization, and compensatory mitigation.

4.7.1 Geology, Topography, and Soils

The Pamlico Sound Bridge Corridor and, to a greater extent, the Parallel Bridge Corridor would result in localized, construction-related changes in topography and soils, especially in low-lying areas (see Section 4.7.3). Potential impacts to area soils would result from fill, vegetation removal and excavation, soil compaction, and erosion. Although many of these impacts would be short-term, a permanent loss of hydric soils and associated function would result from fill activities required for the proposed project. Also, an increase in impervious surface area would result from bridge pile placement. Steps to avoid and minimize impacts to hydric soils are discussed in Section 4.7.10. To minimize soil erosion while construction is underway, an erosion and sedimentation control plan would be prepared in accordance with the Sedimentation Pollution Control Act of 1973, GS 17-3A-50, *et seq.* and GS 113A-50.

4.7.1.1 Pamlico Sound Bridge Corridor

The Pamlico Sound Bridge Corridor would affect estuarine sediments of the Pamlico Sound. Barge traffic and pile placement would disturb sediments, although much of the disturbance would be temporary. However, pile placement would result in permanent loss of estuarine sediment area. The dredging likely required during construction at the shallow portions of the Pamlico Sound Bridge Corridor would result in substantial changes in estuarine sediments and topography. However, dredging would be short-term and likely would fill to near pre-construction contours in areas of active, high-energy currents (see Section 4.7.3).

4.7.1.2 Parallel Bridge Corridor with NC 12 Maintenance

With the Parallel Bridge Corridor, construction-related impacts to sediments would be similar to that of the Pamlico Sound Bridge Corridor, although impacts to estuarine sediments would be less extensive as less of the Parallel Bridge Corridor is over open water. The topography within the Parallel Bridge Corridor is flat, with little change in elevation aside from the dunes adjacent to existing NC 12. Fill material would be required for any construction, including dune maintenance, roadway elevation and/or maintenance, or bridge approach roads.

Temporary impacts from road and bridge construction would be the least for the Parallel Bridge Corridor with Nourishment Alternative, being confined to those impacts associated with the construction of a bridge over Oregon Inlet. The Nourishment Alternative, as well as the nourishment component of the Phased Approach/Rodanthe Nourishment Alternative, however, would require both frequent sand extraction (i.e., dredging) from off-shore borrow sites and beach nourishment for the 50-year planning period. Dredging would result in the removal of existing sediments from two off-shore borrow areas, although sediments from the USACE's ongoing ocean bar dredging also could be used (see Section 2.10.2.1). A total of 6.3 miles (10.1 kilometers) of beach would be subject to nourishment every four years with the Parallel Bridge Corridor with Nourishment Alternative. As indicated in Section 2.10.2.1, 46.6 million cubic yards (35.7 million cubic meters) of sand for dunes and nourishment would be needed through 2060. Approximately 6,000 feet (1,829 meters) would be subject to nourishment with the Parallel

Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative with 21.8 million cubic yards (16.7 cubic meters) of sand needed for nourishment though 2060. Prior investigations of sand extracted from borrow sites suggest that after sand removal, the amount of sand in the sediment decreases while the amount of fine sediments, organic matter, silt, and clay increase (Jutte et al., 2002; Van Dolah et al., 1994). Sand removal effects on sediment quality have been found to persist less than two years to more than ten years after dredging (Jutte et al., 2002; Van Dolah et al., 1998). Recovery time to pre-dredge conditions is variable and depends on the size of the dredged area, local currents, sediment availability, and sediment grain size and composition. The topography of the dredged area also would change substantially after dredging because it is not in a high current area, like the area dredged for the Oregon Inlet and Pamlico Sound bridges (see Section 4.7.1.1). Dredging equipment would create large furrows and depressions within the sand removal area.

4.7.2 Surface Waters and Water Quality

As stated in Chapter 3, all waters in the project area are classified as SA waters (Class A salt waters) with a supplemental classification of High-Quality Waters (HQW). The most stringent application of the Best Management Practices (BMPs) is expected where highway projects affect receiving waters of special designation, such as HQW (NCDOT, August 2003). Construction-related water quality impacts would be similar for both replacement bridge corridors. Both corridors would result in temporary increases in turbidity; however, given the dynamic nature of Oregon Inlet, a temporary increase in turbidity likely would not be notable, as the continuous flux of ocean water through Oregon Inlet would reduce the chances of any permanent water quality problems. Since the Parallel Bridge Corridor lies predominantly over land, there would be less open water construction and, therefore, direct water quality impacts during construction would be of a smaller temporal and spatial scale.

Offshore sand removal and beach nourishment associated with the Parallel Bridge Corridor with Nourishment Alternative could affect water quality by resuspending sediments. These impacts also would occur with the nourishment component of the Phased Approach/Rodanthe Nourishment Alternative, although smaller in scale because nourishment would only occur in the Rodanthe area.

Runoff, created while the highway is in operation, may contribute pollution to nearby ecosystems. Highway runoff can contain varying amounts of heavy metals, nutrients, organic compounds, and particulates, all of which can degrade water quality and impact aquatic organisms (see Section 4.7.3). BMPs identified in North Carolina Department of Environmental and Natural Resources (NCDENR) *Stormwater Best Management Practices Manual* (BMP Manual) (NCDENR, 2007) are capable of removing up to 85 percent of total suspended solids (TSS), 40 percent of total nitrogen (TN) and total phosphorous (TP), 100 percent of ortho-phosphorous (OP), 90 percent of nitrate and nitrite nitrogen (NOx), 97 percent of copper (Cu), and 99 percent of zinc (Zn). The combination of BMPs that can be used in conjunction with this project will be determined when designs are finalized.

4.7.2.1 Pamlico Sound Bridge Corridor

Construction Period Impacts

The primary water quality impacts of the Pamlico Sound Bridge Corridor during construction would result from construction barge traffic, general construction activity, construction channel dredging, and jetting/driving pile placement. All of these activities would cause a temporary

increase in turbidity and a potential decrease in dissolved oxygen levels associated with the resuspension of sediment particles into the water column. Sediments within the affected area have been characterized by the USACE as predominantly fine sand with lesser amounts of silt and clay (USACE, 1980). Given the dynamic nature of Oregon Inlet, a temporary increase in turbidity likely would not be notable, as the continuous flux of ocean water through Oregon Inlet would reduce the chances of any permanent water quality problems. Furthermore, sediments within the project area do not contain significant levels of organic or inorganic pollutants; therefore, disturbance to sediments would not result in detrimental pollutant levels in the water column.

During construction of the Pamlico Sound Bridge Corridor, steps taken to minimize turbidity (when possible and practicable) would include the use of work bridges (rather than dredging for barges) for movement of construction equipment in shallow areas where submerged aquatic vegetation (SAV) is present. If SAV is in waters deep enough to float a barge without dredging, the use of a work bridge would not be necessary. Dredging generally would only be used for approximately 8 miles (12.8 kilometers) in depths less than 6.0 feet (1.8 meters) where SAV is not present and, because the Pamlico Sound Bridge Corridor extends into Pamlico Sound beyond the 6.0-foot (1.8-meter) depth contour, dredging would primarily be restricted to the shallow portions of the alignment near the Rodanthe and Bodie Island termini. Where dredging is needed, the dredging would be to a depth of 8.0 feet (2.4 meters) to 10.0 feet (3.0 meters) to provide more flexibility for construction barge operations and reduce the amount of redredging. Work bridges also would be used to carry construction equipment over intertidal marsh areas (black needlerush and smooth cordgrass). Options for dredged material disposal are discussed in Section 4.13.5. Opportunities to reduce the impact of jetting are discussed in Section 2.10.1.3.

Temporary BMPs also would be implemented prior to the start of construction to manage pollutants associated with construction activities such as sediment, pesticides, fertilizers, petrochemicals, construction chemicals, wash water, paper, wood, garbage, and sanitary waste. Consistent with USEPA guidance (USEPA, 2005), site erosion, sediment, and chemical control measures would include an erosion and sediment control plan detailing provisions such as perimeter controls, stabilization of exposed areas, and construction sequencing that would be implemented prior to the start of construction. Land disturbance activities would be conducted in a manner that reduces erosion, contains sediment on-site during and after construction, prevents off-site transport of waste and chemicals, and minimizes use and production of pollutants. For example, stormwater runoff impacts during construction can be reduced through proper management and disposal of wastes, completing construction in stages so that only a portion of the site is disturbed at a time and then stabilized before the next area is disturbed, and storm drain inlet protection.

Operational Impacts

Given its location and length, the Pamlico Sound Bridge Corridor bridge likely would increase the amount of highway runoff entering Pamlico Sound. Highway runoff can contain varying amounts of sediments, oils, grease, and metals, all of which can degrade water quality. Water quality impacts associated with current NC 12 operations are primarily related to the potential for contamination of receiving surface waters by runoff from impervious roadway surfaces. The impervious areas used to estimate pollutant loadings associated with the existing bridge and highway facility, the Pamlico Sound Bridge Corridor alternatives, and the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are presented in Table 4-16.

Pollutant constituents and concentrations resulting from highway runoff are influenced by several different factors. Consequently, various methods have been developed for estimating pollutant loadings from urban watersheds and highway runoff. Two methods were chosen to evaluate and estimate the pollutant loadings from each of the alternatives studied. One is the Simple Method, a

Table 4-16. Summary of Impervious Areas for the Existing Project Area, Pamlico Sound Bridge Corridor and Parallel Bridge Corridor

	No-Action	Pamlico Sound		Parallel Bridge

Notes:
- Bonner Bridge characteristics for No-Action Alternative obtained from Dare County State Highway Plans (1961).
- Proposed 2.6-mile (4.2-kilometer) long Oregon Inlet bridge for Phased Approaches does not include the temporary maintenance bridge (2,600 feet long by 26 feet wide [792.5 meters by 7.9 meters]) planned during construction.
- Estimated lengths of proposed NC 12 relocation bridges for Phased Approaches do not include the two proposed one-lane frontage roads for the Rodanthe Bridge.

*Preferred Alternative

widely accepted empirically-based model used for estimating pollutant loadings of an urban watershed (Schueler, 1987). This model is consistent with the guidance set forth in NCDENR's BMP Manual.

The second is the FHWA Method, another well-established model developed to estimate pollutant loading resulting from highway runoff (Driscoll et al., 1990). The FHWA method focuses on pollutants contributed by highway segments within a watershed. For comparative analysis purposes, both of these models were used to estimate pollutant loadings associated with each of the alternatives (PB, 2008).

The estimated annual pollutant loadings associated with the Pamlico Sound Bridge Corridor alternatives using the Simple Method and the FHWA Method are summarized in Table 4-17 and Table 4-18, respectively. The receiving surface waters within the project area, Pamlico Sound and Oregon Inlet, are not included on the Impaired Waters List which indicates that water quality uses (e.g., shellfishing) are currently being met (NCDENR, 2006). Therefore, Total Maximum Daily Loads (TMDL), defined as the maximum amount of a pollutant that a water body can receive and still meet water quality standards, have not been developed for these water bodies of interest, so only a comparative analysis with existing conditions (i.e., No-Action Alternative) and between alternatives can be made with respect to water quality impacts.

Table 4-17. Simple Method Summary of Estimated Annual Pollutant Loads for the No-Action (Existing), Pamlico Sound Bridge Corridor, and Parallel Bridge Corridor Alternatives

Pollutant	Pounds per Year (Kilograms per Year)							
	No-Action	Pamlico Sound		Parallel Bridge				
	Bonner Bridge/ NC 12	Curved Terminus	Inter-section Terminus	Nourish-ment	Road North/ Bridge South	All Bridge	Phased Approach/ Rodanthe Bridge*	Phased Approach/ Rodanthe Nourishment
Total Phosphorus	146 (67)	239 (109)	237 (108)	158 (72)	192 (87)	210 (95)	207 (94)	197 (89)
Total Nitrogen	1,126 (512)	1,837 (835)	1,824 (829)	1,213 (551)	1,474 (669)	1,615 (733)	1,596 (724)	1,516 (688)
TSS	30,965 (14,075)	50,507 (22,958)	50,173 (22,806)	33,349 (15,159)	40,544 (18,390)	44,426 (20,151)	43,884 (19,905)	41,696 (18,913)
COD	51,120 (23,236)	83,382 (37,901)	82,831 (37,650)	55,056 (25,026)	66,934 (30,361)	73,343 (33,268)	72,449 (32,862)	68,837 (31,224)
BOD	6,700 (3,045)	10,928 (4,967)	10,856 (4,934)	7,216 (3,280)	8,772 (3,979)	9,612 (4,360)	9,495 (4,307)	9,022 (4,092)
Zinc	99 (45)	162 (73)	161 (73)	107 (49)	130 (59)	142 (64)	140 (64)	133 (60)
Lead	101 (46)	165 (75)	164 (75)	109 (50)	133 (60)	145 (66)	144 (65)	136 (62)
Copper	26 (12)	43 (20)	43 (19)	28 (13)	35 (16)	38 (17)	38 (17)	36 (16)

Note: TSS=Total suspended solids; COD=Chemical oxygen demand; BOD=Biological oxygen demand.
* Preferred Alternative. The relationship of the Phased Approach Alternatives to the shoreline assumes their 2060 high erosion condition.

Table 4-18. FHWA Method Summary of Estimated Annual Pollutant Loads for the No-Action (Existing), Pamlico Sound Bridge Corridor, and Parallel Bridge Corridor Alternatives

Pollutant	Pounds per Year (Kilograms per Year)							
	No-Action	Pamlico Sound		Parallel Bridge

Zinc	48 (22)	67 (30)	67 (30)	51 (23)	59 (27)	64 (29)	61 (28)	
Lead	48 (22)	67 (30)	67 (30)	51 (23)	59 (27)	64 (29)	61 (28)	58 (26)
Copper	13 (6)	19 (9)	18 (8)	14 (6)	16 (7)	17 (8)	17 (8)	16 (7)

Note: TSS=Total suspended solids; COD=Chemical oxygen demand; BOD=Biological oxygen demand.
* Preferred Alternative. The relationship of the Phased Approach Alternatives to the shoreline assumes their 2060 high erosion condition.

Percent increases in annual pollutant loadings with reference to the No-Action Alternative are presented in Table 4-19. These values represent percent increase in annual loadings for each pollutant of concern. This comparative analysis indicates that the Pamlico Sound Bridge Corridor alternatives would result in the greatest increase in annual pollutant loadings, ranging from 39 to 63 percent increase. The results shown in Table 4-19 indicate that the difference between the percent increases in pollutant loadings estimated with the Simple and FHWA methods for each alternative in comparison to existing conditions increases with percent imperviousness. The reason for this is that the runoff coefficients employed in each method are a function of the percent imperviousness of an alternative, but are not linear functions. Once percent imperviousness exceeds 25 percent, the FHWA Method produces runoff coefficient values that are less than those computed using the Simple Method, and this difference between methods increases as percent imperviousness increases. In other words, for the same amount of imperviousness for each project alternative, the Simple Method yields higher stormwater runoff; therefore, it also yields higher pollutant loadings. As stated previously, the Simple Method is the method referenced in NCDENR's BMP Manual. The FHWA method was added for comparison.

Table 4-19. Summary of Percent Increases in Estimated Annual Pollutant Loads in Comparison to the No-Action Alternative

Alternative	Simple Method	FHWA Method
Pamlico Sound		
Curved Terminus	63%	40%
Intersection Terminus	62%	39%
Parallel Bridge		
Nourishment	8%	6%
Road North/Bridge South	31%	23%
All Bridge	43%	33%
Phased Approach/Rodanthe Bridge (Preferred)	42%	28%
Phased Approach/Rodanthe Nourishment	35%	22%

Note: The relationship of the Phased Approach Alternatives to the shoreline assumes their 2060 high erosion condition.

Best Management Practices (BMPs)

Public roads and bridges are considered as "Other Projects" for stormwater management purposes per 15A NCAC 2H.1003). This requires minimization of built-upon area, diversion of stormwater away from surface waters as much as possible, and employment of other BMPs to reduce water quality impacts compliant with NCAC 2H.1000 Stormwater Management. In addition to the state stormwater regulations, stormwater management and controls would be designed with reference to NCDOT's *Stormwater Best Management Practices Toolbox* (BMP Toolbox) (NCDOT, 2008) and NCDENR's BMP Manual. Potential BMPs considered for the alternatives studied and as described in NCDENR's BMP Manual include the following:

- Sand Filter**.** Stormwater runoff infiltrates through a sand media that filters out pollutants.
- Filter Strip. Vegetated section of land providing pollutant removal as stormwater travels over it.
- Grassed Swale. Shallow, vegetated, open channel for filtering pollutants.
- Infiltration Devices. Trenches or basins that allow stormwater runoff to infiltrate into the underlying soil.
- Bioretention**.** Depression in the ground to allow for temporary storage of runoff that is filled with a mixture of soils and plants intended to remove pollutants while providing landscaping and habitat enhancement.
- Stormwater Wetlands**.** Constructed to replicate natural wetlands using physical, chemical, and biological processes to treat runoff and temporary storage of runoff in shallow pools to support vegetation.
- Wet Detention Basin**.** A permanent pool of water is maintained for pollutant removal and additional capacity is available for detaining stormwater runoff.

The applicability of the last three BMPs listed above (bioretention, stormwater wetlands, and wet detention basin) with respect to this project could be limited because of barrier island influences that may include long-term maintenance issues related to wind and water transport of sand and a

seasonal high water table. Stormwater management provisions would be implemented considering water quantity control and pollutant removal capacity for the selected alternative. In general, vegetated conveyance systems and infiltration would be incorporated, and a natural buffer between the roadway and receiving water body would be maintained to the extent feasible.

In order to prevent direct discharge of untreated runoff to the receiving surface waters, treatment prior to discharge is being considered for the Pamlico Sound Bridge Corridor alternatives. Runoff from the proposed bridge replacement will need to be either captured and conveyed to a treatment system on land (i.e., end-of-pipe treatment) or treated directly on the bridge before discharging to Oregon Inlet or Pamlico Sound. Conveyance along the entire 17.5-mile (28.2-kilometer) proposed bridge length may not be feasible because of maintenance and minimum slope (e.g., 0.3 percent recommended for underdrain systems in NCDOT's BMP Toolbox) requirements. However, end-of-pipe treatment is feasible at the northern and southern ends of the Pamlico Sound Bridge Corridor alternatives, but only for the relatively short sections at both ends in which the bridge rises from ground level to the typical bridge height (outside the navigation zone) of 10 feet (3.1 meters). Potential siting for end-of-pipe treatment exists at the northern terminus of the proposed bridge in the vicinity of the Coast Guard Station and Oregon Inlet Marina. At the southern terminus in Rodanthe, undeveloped, open land space exists near the Emergency Ferry Dock terminal on the west side of NC 12. These areas could be able to accommodate an infiltration system or basin facility to which stormwater runoff generated from the northern and/or southern end of the bridge could be conveyed and subsequently treated.

The remaining portion of the bridge through Pamlico Sound requires further consideration of stormwater controls to address bridge deck runoff. Currently, runoff is discharged without treatment from Bonner Bridge directly to Oregon Inlet via drain holes along the bridge length that connect to galvanized steel pipes through which runoff is discharged. Per NCDOT's BMP Toolbox, Bridge Stormwater Controls (BSCs) would be considered and applied appropriately to manage bridge deck runoff, such as designing drainage systems that eliminate direct discharge and applying downstream stormwater controls to treat and mitigate bridge runoff (NCDOT, 2008). The main components of BSCs are bridge type, bridge deck gutter, bridge drainage system, and outlet energy dissipater or stormwater control. Examples of bridge drainage systems provided by NCDOT include a system with no deck drains, a system with no deck drains over the water body, a closed system with longitudinal pipe over the entire bridge length, and a closed system with longitudinal piping over the water body. Essentially, bridge deck runoff falls from deck drains or is routed through a closed system and is then directed to a downstream stormwater control, such as infiltration, before discharging into the receiving water body. BSCs presented in NCDOT's BMP Toolbox, or proprietary devices applicable to controlling bridge deck runoff, would be considered for all bridge replacement segments traversing the receiving water bodies.

As project design moves forward, the NCDOT would incorporate BMPs for stormwater management into the project design.

4.7.2.2 Parallel Bridge Corridor with NC 12 Maintenance

Construction Period Impacts

Construction-related water quality impacts resulting from the Parallel Bridge Corridor would be similar to construction impacts related to the Pamlico Sound Bridge Corridor. However, with the Parallel Bridge Corridor there would be less open water construction and, therefore, direct construction water quality impacts would be of a smaller temporal and spatial scale.

The Parallel Bridge Corridor with Nourishment Alternative would require offshore sand extraction for beach nourishment every four years for the duration of the 50-year planning period. Nourishment of parts of the nourishment area (rotating on a four-year cycle) would occur annually if material from the USACE ocean bar channel dredging were used in the nourishment program. Offshore sand removal could cause a decrease in dissolved oxygen levels by resuspending sediment particles into the water column, or if the pit created by dredging becomes anoxic. A mechanical dredge would likely be used for dredging. BMPs to minimize turbidity include silt curtains, modified operational procedures (slower dredging, fewer dredge deployments), and modified dredge heads (Anchor Environmental, 2003).

Beach nourishment also would generate localized impacts to water quality. Like dredging, the impacts would be primarily related to the resuspension of sediments. These impacts would occur with the Parallel Bridge Corridor with Nourishment Alternative and with the nourishment component of the Phased Approach/Rodanthe Nourishment Alternative, although impacts of the latter alternative would be smaller in scale because nourishment would only occur in the Rodanthe area. Shorelines are high-energy areas, and it is likely that the spike in turbidity would be of short duration and baseline water conditions would return after beach replenishment ceased.

As with construction of the Pamlico Sound Bridge Corridor, steps taken to minimize turbidity (when possible and practicable) would include the use of work bridges (rather than dredging for barges) for movement of construction equipment in shallow areas where SAV is present. Work bridges also would be used to carry construction equipment over intertidal marsh areas (black needlerush and smooth cordgrass) and wetlands on Hatteras Island.

Construction within the ponds in the interior of the Refuge that is associated with the Road North/Bridge South and All Bridge alternatives would generate localized impacts to water quality. These impacts would be temporary and most likely affect turbidity and siltation of sediments.

Overall, a substantial degradation of water quality would not likely result from construction activity in the Parallel Bridge Corridor. Bridge construction activity and dredging and beach nourishment would result in a temporary increase in turbidity and a potential decrease in dissolved oxygen. Opportunities to reduce the impact of jetting for driving piles are discussed in Section 2.10.1.3. Although water quality impacts associated with each dredge/nourishment event are likely to be short-term, dredge and nourishment activity would occur rather frequently (every four years or annually at locations rotated on a four-year cycle) and last through 2060.

Temporary BMPs to manage pollutants associated with construction activities such as sediment, pesticides, fertilizers, petrochemicals, construction chemicals, wash water, paper, wood, garbage, and sanitary waste would be implemented prior to the start of construction. Consistent with USEPA guidance (USEPA, 2005), site erosion, sediment, and chemical control measures would include an erosion and sediment control plan detailing provisions such as perimeter controls, stabilization of exposed areas, and construction sequencing that would be implemented prior to the start of construction.

Operational Impacts

The two Phased Approach alternatives (including the Preferred Alternative) also could permanently affect water quality in the near-shore area by increasing the amount of highway runoff in locations where the bridge would extend east of the 2060 high erosion future shoreline. Highway runoff can contain varying amounts of sediments, oils, grease, and metals, all of which can degrade water quality.

As previously mentioned, water quality impacts associated with current NC 12 operations are primarily related to the potential for contamination of receiving surface waters by runoff from impervious roadway surfaces. Table 4-16 presents the impervious areas used to estimate pollutant loadings associated with the existing bridge and highway facility and the replacement bridge corridor alternatives. The estimated annual pollutant loadings associated with the Parallel Bridge Corridor alternatives using the Simple Method and the FHWA Method are presented in Table 4-17 and Table 4-18, respectively.

Percent increases in annual pollutant loadings with reference to the No-Action Alternative are presented in Table 4-19. These values represent percent increase in annual loadings for each pollutant of concern. This comparative analysis indicates that the Parallel Bridge Corridor with Nourishment Alternative would result in the least change in annual pollutant loadings (ranging from 6 to 8 percent increase) with respect to existing conditions (Table 4-19). The increases in annual pollutant loadings for the four remaining Parallel Bridge Corridor alternatives are similar, as follows (from least to greatest increase): 23 to 31 percent for Road North/Bridge South; 22 to 35 percent for Phased Approach/Rodanthe Nourishment; 28 to 42 percent for Phased Approach/ Rodanthe Bridge Alternative (Preferred); and 33 to 43 percent for All Bridge (Table 4-19).

Best Management Practices (BMPs)

Similar to the Pamlico Sound Bridge Corridor alternatives, BMP treatments of runoff from the proposed Oregon Inlet bridge with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) prior to discharge into Oregon Inlet are being considered. The Oregon Inlet bridge length of between 2.6 and 3.2 miles (4.2 and 5.1 kilometers) for the Parallel Bridge Corridor alternatives is substantially shorter than the Pamlico Sound bridge (17.5-mile [28.2-kilometer] length); however, conveyance of highway runoff along the entire bridge length may still be infeasible because of slope requirements for pipe conveyance and maintenance requirements. Nevertheless, conveyance of bridge runoff may be possible for a longer portion of the total bridge length as compared to the Pamlico Sound Bridge Corridor alternatives since the proposed Oregon Inlet bridge is shorter. An end-of-pipe treatment could be feasible at the northern terminus as described above in the vicinity of the Oregon Inlet Marina to which a portion of the northern end of the proposed Oregon Inlet bridge could be conveyed. Similarly, there are potential land side treatment sites at the southern terminus of the proposed Oregon Inlet bridge near an existing parking area that accesses the existing catwalks and at the northern end of the Refuge. However, these sites would use land from the Refuge and could be found incompatible with the mission of the Refuge.

For the remaining portion of the Oregon Inlet bridge for all Parallel Bridge Corridor alternatives (including the Preferred Alternative), BSCs would be considered and applied appropriately to manage bridge deck runoff such as designing drainage systems that eliminate direct discharge and applying downstream stormwater controls to treat and mitigate bridge runoff as presented in NCDOT's BMP Toolbox. As discussed above for the Pamlico Sound Bridge Corridor alternatives, BSCs presented in NCDOT's BMP Toolbox, or proprietary devices applicable to controlling bridge deck runoff, would be considered for all bridge replacement segments traversing the receiving water bodies.

The Nourishment Alternative would include maintenance of the existing 12.5-mile (20.1-kilometer) long NC 12 roadway through the project area, supplemented with beach nourishment. Grassed swales or filtration trenches could be constructed along the roadway shoulders to address highway runoff resulting from the existing roadway. Depending on the space available and treatment capacity, these could be supplemented with other recommended BMPs such as bioretention and stormwater wetlands, as necessary. Some vegetated trenches and wetland areas

currently exist through portions of the Refuge; therefore, trenches or swales could be used to convey and pre-treat runoff before tying into existing systems. This applies to the unchanged NC 12 segments and new roadways within the current easement specified for the remaining Parallel Bridge Corridor alternatives.

For the Phased Approach alternatives (including the Preferred Alternative), all of the Phase II, III, and IV bridges would be built over land within the existing NC 12 easement, but as the shoreline erodes, much of their length would be over water by 2060. When initially built over land, BSCs could include deck drains that route runoff to BMPs such as grassed swales which may be required to control and pre-treat the stormwater discharge and prevent erosion of the underlying land. This also would apply to the proposed bridges passing through the Refuge with the All Bridge Alternative. However, once the shoreline erodes and substantial lengths of the Phased Approach bridges are over water, these types of BSCs would no longer be possible for the entire length of the bridges. Subsequently, water quality in the near-shore area could be affected by the increasing amount of highway runoff discharged directly into the ocean. Therefore, BMPs for the Phased Approach alternatives' bridges over Hatteras Island would take into consideration the eventual location of substantial portions of these bridges over the beach and in the Atlantic Ocean.

The Road North/Bridge South and All Bridge alternatives would incorporate a new bridge at the southern end of the project area that passes over Pamlico Sound. Appropriate BSCs would be implemented to treat bridge deck runoff prior to discharge into the sound.

For Parallel Bridge Corridor bridges terminating in Rodanthe, bridge runoff could be conveyed to the southern terminus of the bridge and then to the undeveloped land near the Emergency Ferry Dock that is a potential site for similar BMPs with the Pamlico Sound Bridge Corridor alternatives.

Similar to the Pamlico Sound Bridge Corridor alternatives, the NCDOT would incorporate BMPs for stormwater management into the project design. Temporary BMPs to manage pollutants associated with construction activities, such as sediment, pesticides, fertilizers, petrochemicals, construction chemicals, wash water, paper, wood, garbage, and sanitary waste, would be implemented prior to the start of construction. Consistent with USEPA guidance (USEPA, 2005), site erosion, sediment, and chemical control measures would include an erosion and sediment control plan detailing provisions such as perimeter controls, stabilization of exposed areas, and construction sequencing that would be implemented prior to the start of construction.

4.7.3 Biotic Communities

Construction activities within the Pamlico Sound Bridge and the Parallel Bridge corridors would result in biological impacts in an extensive, sensitive, and highly productive coastal ecosystem. The Pamlico Sound Bridge Corridor alternatives would fill mostly man-dominated uplands. A bridge with a Curved Rodanthe Terminus would fill 2.0 acres (0.8 hectare) more than the Intersection Rodanthe Terminus. Since most fill impacts for both options would be to man-dominated uplands, the Pamlico Sound Bridge Corridor would not result in a substantial loss of natural biotic communities. The biotic communities fill impacts for the replacement bridge corridor alternatives, in order from greatest to least, would be as follows:

- Road North/Bridge South: 91.6 acres (37.1 hectares);
- Nourishment: 24.6 acres (10.0 hectares);

- All Bridge: 17.2 acres (7.0 hectares);
- Phased Approach/Rodanthe Bridge (Preferred): 16.2 acres (6.6 hectares);
- Pamlico Sound Bridge Corridor alternatives: 10.8 to 12.8 acres (4.4 to 5.2 hectares); and
- Phased Approach/Rodanthe Nourishment: 9.5 acres (3.9 hectares).

As seen above, all of the replacement bridge corridor alternatives, except the Parallel Bridge Corridor with Road North/Bridge South Alternative, would be of a similar order of magnitude in terms of fill impacts, with a maximum difference between these alternatives of 15.1 acres (6.1 hectares).

4.7.3.1 Pamlico Sound Bridge Corridor

Habitat modifications with the Pamlico Sound Bridge Corridor would result from shading and fill activities (construction fill and pile placement). Table 4-20 shows the total area of each biotic community that would be affected directly by fill. Shading impacts on wetland biotic communities are described in Section 4.7.4.

The Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus would fill mostly man-dominated uplands (5.7 acres [2.3 hectares]). Fill also would be placed as follows:

- 0.9 acre (0.4 hectare) on dunes;
- 1.2 acres (0.5 hectare) on wetland man-dominated;
- 0.5 acre (0.2 hectare) on maritime grassland wetlands;
- 0.1 acre (0.04 hectare) on wetland maritime shrub thicket; and
- 1.4 acres (0.6 hectare) on upland maritime shrub thicket.

On Bodie Island, a less than 0.01 acre (0.01 hectare) area of both smooth cordgrass and black needlerush wetlands would be affected by pile placement. Open water and SAV impacts would result from pile placement alone and total 2.7 acres (1.1 hectares) and 0.3 acre (0.1 hectare), respectively.

The Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus also would fill mostly man-dominated uplands (5.3 acres [2.1 hectares]). Fill also would be placed as follows:

- 0.9 acre (0.3 hectare) on dunes;
- 0.4 acre (0.2 hectare) on wetland man-dominated;
- 0.5 acre (0.2 hectare) on maritime grassland wetlands;
- 0.3 acre (0.1 hectare) on wetland maritime shrub thicket; and
- 0.5 acre (0.2 hectare) on upland maritime shrub thicket.

Table 4-20. Construction Fill and Pile Placement Impacts to Biotic Communities with the Pamlico Sound Bridge Corridor

Biotic Community	Subject to Section 404 Jurisdictional?	Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus in Acres (hectares)	Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus in Acres (hectares)
Open water			
• Aquatic bottom	Yes	2.69 (1.09)	2.70 (1.09)
• Submerged aquatic vegetation (SAV)	Yes	0.31 (0.13)	0.30 (0.12)
• Impoundments	Yes	0.00 (0.00)	0.00 (0.00)
Beach	No	0.00 (0.00)	0.00 (0.00)
Dunes	No	0.89 (0.36)	0.85 (0.34)
Wetland man-dominated	Yes	1.19 (0.48)	0.40 (0.16)
Upland man-dominated	No	5.65 (2.29)	5.27 (2.13)
Wetland salt shrub/grasslands	Yes	0.00 (0.00)	0.00 (0.00)
Upland salt shrub/grasslands	No	0.00 (0.00)	0.00 (0.00)
Wetland maritime grassland	Yes	0.52 (0.21)	0.46 (0.19)
Upland maritime grassland	No	0.00 (0.00)	0.00 (0.00)
Wetland overwash	Yes	0.00 (0.00)	0.00 (0.00)
Upland overwash	No	0.00 (0.00)	0.00 (0.00)
Wetland maritime shrub thicket	Yes	0.11 (0.04)	0.30 (0.12)
Upland maritime shrub thicket	No	1.43 (0.58)	0.54 (0.22)
Wetland reed stand	Yes	0.00 (0.00)	0.00 (0.00)
Upland reed stand	No	0.00 (0.00)	0.00 (0.00)
Salt flat[1]	Yes	0.00 (0.00)	0.00 (0.00)
Brackish marsh[1]	Yes	0.00 (0.00)	0.00 (0.00)
Smooth cordgrass[1]	Yes	<0.01 (<0.01)	<0.01 (<0.01)
Wetland black needlerush[1]	Yes	<0.01 (<0.01)	<0.01 (<0.01)
Upland black needlerush	No	0.00 (0.00)	0.00 (0.00)
TOTAL IMPACT		**12.81 (5.18)**	**10.84 (4.39)**

[1]CAMA coastal wetlands.

NOTE:

- Calculated areas are based on conditions as verified with the USACE through January 2004.
- Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

Again, on Bodie Island, a less than 0.01 acre (0.01 hectare) area of both smooth cordgrass and black needlerush wetlands would be affected by pile placement. Open water impacts would result from pile placement alone and would total approximately 2.7 acres (1.1 hectares). SAV fill totaling 0.3 acre (0.1 hectare) also would result from pile placement.

Since most fill impacts for both options would be to man-dominated uplands, neither Rodanthe terminus option would result in a substantial loss of natural biotic communities. Fill impacts to the most important biotic communities, such as SAV, would be the same for either terminus option.

Construction dredging would affect Pamlico Sound. Construction of the Pamlico Sound Bridge Corridor could be accomplished most easily and economically by working directly from barges used for shipping materials to the construction site (see Section 2.9.5). For part of the Pamlico Sound Bridge Corridor, construction barges could float above the bottom of Pamlico Sound without dredging a channel. In waters less than 6.0 feet (1.8 meters), however, dredging would be needed. The dredge channel would be approximately 100 feet (30.5 meters) wide.

Approximately 9 miles (14.4 kilometers) of the Pamlico Sound Bridge Corridor is in waters less than 6 feet (1.8 meters) in depth. Of that distance, SAV is on the sound bottom for approximately 1 mile (1.6 kilometers), based on the most recent SAV mapping. Here, a work bridge would be used instead of barges. Dredging would occur along the remaining 8 miles (12.8 kilometers). Thus, it is estimated that approximately 100 acres (40.5 hectares) of aquatic bottom would be dredged to create a channel along the Pamlico Sound Bridge Corridor for use by construction barges. Where dredging is needed, the dredging would be to a depth of 8 feet (2.4 meters) to provide more flexibility for construction barge operations and reduce the need for redredging. Indirect dredging effects on biotic communities would result from increased turbidity, noise, and siltation; this activity might cause temporary reductions in adjacent communities' plant and animal components. Also, the potential increase in turbidity and sedimentation would reduce light penetration, affecting photosynthesis by phytoplankton and SAV.

Although dredging is required, the loss of SAV would be minimal because most of the known permanent SAV beds in the project area are east of the Pamlico Sound Bridge Corridor and because work bridges, rather than dredging, would be used in portions of the bridge corridor that contain SAV. The Pamlico Sound Bridge Corridor, by nature of its location near Oregon Inlet in deeper sound waters, would minimize impacts to SAV beds.

Work bridges also would be used during construction over SAV areas and intertidal marsh areas (black needlerush and smooth cordgrass) at the Bodie Island end of the Pamlico Sound Bridge Corridor bridge.

Some habitat would be regained (143.6 acres [58.1 hectares]) with the Pamlico Sound Bridge alternatives because the existing NC 12 pavement would be removed and replanted with native vegetation. This habitat would not be equivalent to native, undisturbed habitat. However, potential habitat created by the removal of NC 12 could be colonized very quickly by ephemeral species that inhabit maritime islands. Natural shoreline movement, allowed to occur after the removal of NC 12 maintenance dunes, also would contribute to naturalizing this area of the Outer Banks, and benefiting wildlife in the Refuge.

4.7.3.2 Parallel Bridge Corridor with NC 12 Maintenance

Table 4-21 shows the total area of each biotic community that would be affected directly by fill (construction fill and pile placement) from the Parallel Bridge Corridor and its five alternatives. Shading impacts on wetland biotic communities are described in Section 4.7.4. The biotic communities fill impacts for the Parallel Bridge Corridor alternatives, in order from greatest to least, would be as follows:

- Road North/Bridge South: 91.6 acres (37.1 hectares);
- Nourishment: 24.6 acres (10.0 hectares);
- All Bridge: 17.2 acres (7.0 hectares);
- Phased Approach/Rodanthe Bridge (Preferred): 16.2 acres (6.6 hectares); and
- Phased Approach/Rodanthe Nourishment: 9.5 acres (3.9 hectares).

Most fill impacts for all five Parallel Bridge Corridor alternatives would be to wetland open water, wetland black needlerush, wetland salt shrub/grassland, upland dune, and upland maritime shrub thicket. Fill impacts to SAV would be the same for the All Bridge and Road North/Bridge South alternatives (1.4 acres [0.6 hectare]). The Nourishment Alternative would affect 0.2 acre (0.1 hectare) of SAV. Fill impacts of the two Phased Approach alternatives (including the Preferred Alternative) would be comprised mostly of open water (2.44 acres [0.99 hectare]) and upland man-dominated (11.6 acres [4.7 hectares] with Rodanthe Bridge and 5.9 acres [2.4 hectares] with Rodanthe Nourishment). The two Phased Approach alternatives would affect 0.2 acre (0.1 hectare) of SAV.

Some habitat partially occupied by the bridges along the NC 12 easement would be regained with the Road North/Bridge South (106.1 acres [42.9 hectares]), All Bridge (100.4 acres [40.6 hectares]), and two Phased Approach alternatives (including the Preferred Alternative) (117.1 acres [47.4 hectares]). As projects are built, the existing NC 12 pavement would be removed and replanted with native vegetation. Temporary work roads associated with the Phased Approach alternatives also would be removed and replanted with native vegetation. This habitat would not be equivalent to native, undisturbed habitat. However, potential habitat created by the removal of NC 12 could be colonized very quickly by ephemeral species that inhabit maritime islands. Natural shoreline movement, allowed to occur except with the alternatives involving nourishment, also would contribute to naturalizing this area of the Outer Banks, and possibly benefit wildlife in the Refuge.

Like the Pamlico Sound Bridge Corridor, dredging during construction would affect Oregon Inlet. Construction of the Oregon Inlet bridge could be accomplished most easily and economically by working directly from barges used for shipping materials to the construction site (see Section 2.10.1.3). For much of the area of the Oregon Inlet bridge, construction barges could float above the bottom of the inlet without dredging a channel. In waters less than 6.0 feet (1.8 meters), however, an alternative would be needed. Thus, in the area near the northern end of Hatteras Island where the sand bars are shoaling, a dredge channel would likely be required approximately 120 feet (36.6 meters) wide and approximately 30 feet from the bridge. Use of a temporary haul road could be used west of Bodie Island.

Table 4-21. Total Construction Fill and Pile Placement Impacts to Biotic Communities with the Parallel Bridge Corridor

Biotic Community	Subject to Section 404 Jurisdic-tions?	Parallel Bridge Corridor with Nourish-ment Alternative in Acres (hectares)	Parallel Bridge Corridor with Road North/Bridge South Alternative in Acres (hectares)	Parallel Bridge Corridor with All Bridge Alternative in Acres (hectares)	Parallel Bridge Corridor with Phased Approach/ Rodanthe Bridge Alternative in Acres (hectares)	Parallel Bridge Corridor with Phased Approach/ Rodanthe Nourishment Alternative in Acres (hectares)

TOTAL IMPACT		**24.58 (9.95)**	**91.60 (37.07)**	**17.22 (6.97)**	**16.24 (6.57)**	**9.53 (3.86)**

[1]CAMA coastal wetlands.

NOTE:

- Calculated areas are based on conditions as verified with the USACE through June 2005.
- Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

*Preferred Alternative

Approximately 2,000 feet (610 meters) of the Oregon Inlet bridge in the Oregon Inlet Shoal area is likely to be in less than 6.0 feet (1.8 meters) of water. Approximately 5.5 acres (2.2 hectares) of aquatic bottom would be dredged to create a channel that is 120 feet (61 meters) wide for use by construction barges. Indirect dredging effects on biotic communities would result from increased turbidity, noise, and siltation; this activity might cause temporary reductions in adjacent communities' plant and animal components. Also, the potential increase in turbidity and sedimentation would reduce light penetration, affecting photosynthesis by phytoplankton and SAV.

A temporary haul road could be built for construction of the north approach spans on the Bodie Island end of the Oregon Inlet bridge. It would be placed on the west side of the new bridge near the outside edge of the foundations. It would affect 6.5 acres (2.6 hectares) of biotic communities, including 0.5 acre (0.2 hectare) of wetland black needlerush, 0.4 acre (0.2 hectare) of wetland maritime shrub thicket, 4.5 acres (1.8 hectares) of wetland open water/SAV (2.4 acres [0.9 hectare] of SAV affected), 0.6 acre (0.2 hectare) of smooth cordgrass, 0.2 acre (0.1 hectare) of upland dune, and 0.3 acre (0.1 hectare) of upland maritime shrub thicket. Dredging the area could be an alternative to a haul road. Use of a work bridge instead of a haul road or dredging, particularly for short distances at critical locations, such as SAV locations, would be considered prior to construction. Reasons for use of a temporary haul road are described in Section 2.10.1.3. The effects of a temporary haul road depend on the nature of the subsoil. If the subsoil is marine sand with little organic accumulation, the impacts would be minimal, involving only distortion of the upper root zone. To avoid the risk of permanent damage to plants within the footprint of the haul road, they could be transplanted to a "heeling-in" area until the demolition operation was completed. Following construction activities and removal of the temporary road, the plants could be planted and re-established in their original bed. If, however, there is a substantial organic or muck layer beneath the marsh, the construction of a temporary haul road would cause permanent changes in the marsh resulting from consolidation and distortion of the subsoil. Changes in biodiversity, as well as organic productivity, could be a direct result of the compaction and distortion of these marine sediments. However, the likelihood of there being a substantial area of organic material under the haul road is remote. There is only a thin layer of organic material covering sand in this area, which is not compactable. Therefore, the possibility of compaction is minimal.

Although dredging and a temporary haul road would be required to construct the Oregon Inlet bridge, the loss of SAV would be minimal because most of the known permanent SAV beds in the project area are west of the Parallel Bridge Corridor (except in the Rodanthe and Bodie Island areas) and because work bridges, rather than dredging, would be used in portions of the bridge corridor that contain SAV.

When working over water where SAV is present or over wetlands, other bridges associated with the Road North/Bridge South and All Bridge alternatives in the Rodanthe area would be erected from a work bridge. Most of the area over which the bridges would pass is classified as wetland. Given the closeness of the Rodanthe area bridge to the west side of Hatteras Island, it is expected that SAV would be present along most, if not all, of the bridge length over water.

In addition to the temporary construction impacts described above for the other Parallel Bridge Corridor alternatives, the Phased Approach alternatives (including the Preferred Alternative) would have temporary habitat impacts of 48.5 acres (19.6 hectares) as a result of temporary traffic maintenance roads, as described in Section 2.10. Table 4-22 shows the total area of each biotic community that would be temporarily affected by these roads. These impacts generally would be within the Refuge and would be the same for both Phased Approach alternatives. The habitat affected the greatest by these temporary roads would be man-dominated uplands (20.7 acres [8.4 hectares]). Temporary road fill also would be placed in 27.8 acres (11.2 hectares) of

Table 4-22. Temporary Construction Fill and Pile Placement Impacts to Biotic Communities with the Parallel Bridge Corridor with Phased Approach Alternatives (including the Preferred Alternative)

Biotic Community	Subject to Section 404 Jurisdiction?	Parallel Bridge Corridor with Phased Approach Alternatives in Acres (hectares)
Open water		
• Aquatic bottom	Yes	0.61 (0.25)
• Submerged aquatic vegetation (SAV)	Yes	0.00 (0.00)
• Impoundments	Yes	0.22 (0.09)

Smooth cordgrass[1]	Yes	0.00 (0.00)
Wetland black needlerush[1]	Yes	0.96 (0.39)
Upland black needlerush	No	1.00 (0.40)
TOTAL IMPACT		**48.50 (19.63)**

[1]CAMA coastal wetlands.

- Calculated areas are based on conditions as verified with the USACE through June 2005.
- Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

15 non-man-dominated habitat types with impacts ranging from 0.23 acre (0.09 hectare) to 8 acres (3.2 hectares) as shown in Table 4-22. A potential construction haul road on Bodie Island would affect 2.4 acres (0.97 hectare) of SAV.

Temporary traffic management roads built within the existing NC 12 easement would affect 10.4 acres (4.2 hectares) twice. Initial temporary impacts, accounted for in Table 4-22, would be affected a second time when Phase II and Phase III permanent bridges are lengthened in Phase IV. Temporary roads would be needed adjacent to the approach bridges and fills that took earlier phases back down to ground level to allow their removal prior to extending the full height bridge as a part of the next phase. The first impact would be to the current habitat type. The second impact would affect areas replanted with native vegetation after the completion of Phase II or III. The length of time between impacts would be approximately 10 years (when connecting Phase III bridge to Phase IV) to 18 years (when connecting Phase III bridges to Phase IV) assuming the phasing schedule presented in Section 2.10.2.5.

With the Phased Approach alternatives (including the Preferred Alternative), the habitat affected by the completed bridges would change from what is described above over time as the shoreline erodes under the bridges. Table 4-23 shows how this impact would change from 2020 to 2060 for the Phased Approach/Rodanthe Bridge Alternative (Preferred). The table indicates that over time the portion of Phases II to IV in the ocean would increase while the length of beach would decline somewhat after peaking in 2020. During construction, the entire Phase II to IV project would be within the "other" habitat category because Phases II and IV would not be constructed on the beach or in the ocean. The wet beach area is the intertidal zone under the jurisdiction of the USACE under Section 404 of the Clean Water Act.

4.7.4 Wetlands and Open Water Habitat

In terms of Section 404 (Clean Water Act) jurisdictional areas impact, the Parallel Bridge Corridor with Road North/Bridge South Alternative would have the largest impact of the replacement bridge corridor alternatives at 78.2 acres (31.6 hectares), consisting of 50.7 acres (20.5 hectares) of wetland and 27.4 acres (11.1 hectares) of open water. The jurisdictional area impact of the other six replacement bridge corridor alternatives would be at a comparable order-of-magnitude with the All Bridge Alternative being the greatest at 12.3 acres (5.0 hectares), including 6.7 acres (2.7 hectares) of wetland and 5.7 acres (2.3 hectares) of open water, and the Phased Approach alternatives (including the Preferred Alternative) being the least at 3.1 acres (1.3 hectares). Fill of CAMA coastal wetlands also would be greatest (11.8 acres [4.8 hectares]) with the Road North/Bridge South Alternative.

The Parallel Bridge Corridor bridge structure would shade mostly open water. Shading impacts to SAV and wetland biotic communities on Bodie Island and Hatteras Island would vary between the five alternatives, with the All Bridge Alternative having the greatest impact at approximately 44.5 acres (18.0 hectares), including 17.0 acres (6.9 hectares) of wetland and 27.5 acres (11.1 hectares) of open water, and the Nourishment Alternative having the least impact at approximately 10.1 acres (4.1 hectares), including 1.5 acres (0.6 hectare) of wetland and 8.6 acres (3.5 hectares) of open water. The Pamlico Sound bridge structure would shade mostly open water. Shading impacts to SAV and the wetland biotic communities would be up to 84.9 acres (34.4 hectares), including 1.2 acres (0.5 hectare) of wetland and 83.7 acres (33.9 hectares) of open water.

[a] Based on bridge length times width of 42.5 feet (13.0 meters).
[b] Wet beach habitat is area between low tide shoreline and 100 feet (30.5 meters) landward, based on average width estimated from 2007 aerial photography.
[c] Dry beach habitat is area between 100 and 200 feet (30.5 meters and 61.0 meters) landward of low tide shoreline, based on average width estimated from 2007 aerial photography.
[d] Other habitat is habitat not in ocean or on beach.

All of the Parallel Bridge Corridor alternatives also could have temporary Section 404 jurisdictional area impacts, associated with a temporary haul road for Oregon Inlet bridge construction access on Bodie Island, of approximately 6.0 acres (2.4 hectares), including 1.5 acres (0.6 hectare) of wetland and 4.5 acres (1.8 hectares) of open water. These temporary impacts also would include approximately 1.1 acres (0.4 hectare) of CAMA coastal wetlands. The two Phased Approach alternatives (including the Preferred Alternative) would result in an additional 6.5 acres (2.6 hectares) of temporary jurisdictional area impacts associated with construction of a temporary traffic maintenance road within the existing NC 12 easement on Hatteras Island, including 5.6 acres (2.3 hectares) of wetland and 0.8 acre (0.3 hectare) of open water. The total temporary jurisdictional area impacts for the Phased Approach alternatives (including the Preferred Alternative) would be 12.5 acres (5.0 hectares), including 7.1 acres (2.9 hectares) of wetland and 5.3 acres (2.2 hectares) of open water.

4.7.4.1 Pamlico Sound Bridge Corridor

The areas of individual jurisdictional community types affected by shading and by fill and pile placement for the Pamlico Sound Bridge Corridor with Curved Rodanthe Terminus and the Pamlico Sound Bridge Corridor with Intersection Rodanthe Terminus are listed in Table 4-24.

A bridge in the Pamlico Sound Bridge Corridor would fill 4.8 acres (2.0 hectares) of jurisdictional areas with the Curved Rodanthe Terminus, including 1.8 acres (0.7 hectare) of wetland and 3.0 acres (1.2 hectares) of open water. The fill impact to jurisdictional areas would be 4.2 acres (1.7

hectares) with the Intersection Rodanthe Terminus, including 1.2 acres (0.5 hectare) of wetland and 3.0 acres (1.2 hectares) of open water. Fill of CAMA coastal wetlands (salt flat, brackish marsh, smooth cordgrass, and black needlerush) would each make up less than 0.01 acre (0.01 hectare) of this total. Fill in jurisdictional areas would primarily affect man-dominated wetlands, maritime shrub thicket wetlands, maritime grassland wetlands, and open water/aquatic bottom.

The Pamlico Sound Bridge Corridor's bridge structure also would shade Section 404 jurisdictional areas (see Table 4-24). The bridge structure would be approximately 40 feet (12.2 meters) wide and the bottom of its superstructure generally would be 10 feet (3.1 meters) above mean high water. The Pamlico Sound bridge structure would shade mostly open water. Shading impacts to SAV and the wetland biotic communities on Bodie Island and Hatteras Island would be similar under either terminus option at up to 84.9 acres (34.4 hectares), including 1.2 acres (0.5 hectare) of wetland and 83.7 acres (33.9 hectares) of open water. Less than 1 acre (0.4 hectare) of CAMA coastal wetlands would be shaded with either alternative.

Table 4-24. Shading, Fill, and Pile Placement Impacts to Wetlands and Waters for the Pamlico Sound Bridge Corridor

[1] Indicates area of SAV based on unpublished NOAA/DMF mapping and limited ground truthing of imagery taken during 1985-1990. A survey conducted in September 2007 indicated that the current area of SAV coverage is similar to that reported when previous mapping was conducted (NCDOT, 2007).
[2] CAMA coastal wetlands.
NOTE: Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

During construction, a work bridge would be used over intertidal marsh areas (black needlerush and smooth cordgrass) at the Bodie Island end of the Pamlico Sound bridge.

No practicable alternatives exist that would avoid impacts to Section 404 and CAMA coastal wetlands because of the pervasive nature of the resource. Where fill or pile placement is not required, the loss of flora and fauna associated with construction activity would be short-term. Also, the permanent loss of wetland habitat and function would be replaced through required compensatory mitigation. Mitigation is discussed in Section 4.7.10.

The bulk of the area affected by dredging and jetting/driving pile placement would be unvegetated aquatic bottom. The dynamics of the project area suggest that the bottom sand would, however, replenish itself over time, and losses would be temporary and short-term. Dredging is not planned in areas containing SAV. However, turbidity and siltation induced by dredging and the jetting-during-driving pile installation process could disturb or eliminate SAV in the vicinity of these activities. Opportunities to reduce the impact of jetting are discussed in Section 2.10.1.3.

4.7.4.2 Parallel Bridge Corridor with NC 12 Maintenance

The areas of individual Section 404 jurisdictional community types affected by shading and by fill and pile placement for the Parallel Bridge Corridor alternatives are listed in Table 4-25.

A bridge and/or relocated NC 12 in the Parallel Bridge Corridor would have the greatest fill impacts on jurisdictional areas with the Road North/Bridge South Alternative at approximately 78.2 acres (31.6 hectares), consisting of 50.7 acres (20.5 hectares) of wetland and 27.4 acres (11.1 hectares) of open water. The Nourishment Alternative would fill approximately 4.3 acres (1.7 hectares) of jurisdictional areas, consisting of 1.7 acres (0.7 hectare) of wetland and 2.6 acres (1.1 hectares) of open water. The All Bridge Alternative would fill 12.3 acres (5.0 hectares) of jurisdictional areas, consisting of 6.7 acres (2.7 hectares) of wetland and 5.7 acres (2.3 hectares) of open water. Both Phased Approach alternatives (including the Preferred Alternative) would fill approximately 3.1 acres (1.3 hectares) of jurisdictional areas. In addition, the Nourishment Alternative would require up to 76.5 acres (31.0 hectares) of jurisdictional intertidal beach to be nourished with sand (i.e., a rectangular area in the intertidal zone approximately 6.3 miles [10.1 kilometers] long by 100 feet [30.5 meters] wide) and the Phased Approach/Rodanthe Nourishment Alternative would require beach nourishment of up to 13.8 acres (5.6 hectares) (i.e., a rectangular area in the intertidal zone approximately 6,000 feet [1,829 meters] long by 100 feet [30.5 meters] wide).

Fill of CAMA coastal wetlands would be the greatest with the Road North/Bridge South Alternative at approximately 11.8 acres (4.8 hectares), consisting of 11.6 acres (4.6 hectares) of wetland black needlerush and 0.2 acre (0.1 hectare) of smooth cordgrass. The All Bridge Alternative would fill approximately 2.2 acres (0.9 hectare) of CAMA coastal wetlands (2.0 acres [0.8 hectare] of wetland black needlerush and 0.2 acre [0.1 hectare] of smooth cordgrass), whereas the Nourishment Alternative would only fill approximately 0.3 acre (0.1 hectare) of CAMA coastal wetlands. The two Phased Approach alternatives (including the Preferred Alternative) would fill 0.3 acre (0.1 hectare) of CAMA coastal wetlands (0.1 acre [0.1 hectare] of black needlerush and 0.2 acre [0.1 hectare] of smooth cordgrass). CAMA wetland fill would primarily affect maritime shrub thicket wetlands, salt shrub grassland wetlands, and open water/impoundments.

- Calculated areas are based on conditions as verified with the USACE through June 2005.
- Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

*Preferred Alternative

The Parallel Bridge Corridor's bridge structure also would shade Section 404 jurisdictional areas (see Table 4-25). The bridge structure on Hatteras Island and west of Rodanthe with the Road North/Bridge South and All Bridge alternatives would be approximately 40 feet (12.2 meters) wide (clear roadway width) and the bottom of its superstructure generally would be 10 feet (3.1 meters) above mean high water. The bridge structure on Hatteras Island with the Phased Approach alternatives (including the Preferred Alternative) would be 40 feet (12.2 meters) wide (clear roadway width) and the bottom of its superstructure generally would be 25 feet (7.6 meters) above mean high water. The Oregon Inlet bridge also would be approximately 40 feet (12.2 meters) wide (clear roadway width). Its height would vary. When west of Bodie Island it would be approximately 75 feet (22.9 meters) above mean high water. At its Hatteras Island terminus the superstructure would be 25 to 70 feet (7.6 to 21.3 meters) above mean high water as it enters the Island depending on the alternative, but would quickly drop to ground or to a bridge 10 feet (3.1 meters) above ground level with the All Bridge Alternative. The proposed bridge structure would shade mostly open water and salt shrub/grassland wetlands. Shading impacts to SAV and wetland biotic communities on Bodie Island and Hatteras Island would vary between the five alternatives, with the All Bridge Alternative having the greatest impact at approximately 44.5 acres (18.0 hectares), including 17.0 acres (6.9 hectares) of wetland and 27.5 acres (11.1 hectares) of open water, and the Nourishment Alternative having the least impact at approximately 10.1 acres (4.1 hectares), including 1.5 acres (0.6 hectare) of wetland and 8.6 acres (3.5 hectares) of open water. Shading impacts to SAV and wetland biotic communities would be 18.7 acres (7.6 hectares) with the Road North/Bridge South Alternative, including 3.2 acres (1.3 hectares) of wetland and 15.6 acres (6.3 hectares) of open water. For the Phased Approach/Rodanthe Bridge Alternative (Preferred), the shading impacts would be approximately 10.4 acres (4.2 hectares), including 4.0 acres (1.6 hectares) of wetland and 6.4 acres (2.6 hectares) of open water. For the Phased Approach/Rodanthe Nourishment Alternative, the shading impacts would be approximately 10.2 acres (4.1 hectares), including 3.8 acres (1.6 hectares) of wetland and 6.4 acres (2.6 hectares) of open water. No more than approximately 5.6 acres (2.2 hectares) of CAMA coastal wetlands would be shaded with any one alternative.

Because of the phased timeline of construction with the Phased Approach alternatives (including the Preferred Alternative), wetland impacts could be less in Phases III and IV since westward sand movement within the Refuge could fill what are now considered wetlands in the NC 12 easement before bridge construction begins. It is unlikely that future shoreline erosion and associated habitat change will result in greater wetland impacts during future construction phases than those that exist today. This is because future overwash is likely to fill eastern portions of existing wetland. New wetland formation as a result of overwash or westward migration is likely to occur west of the NC 12 easement into which the Phased Approach alternatives would be placed.

During construction of any of the Parallel Bridge Corridor alternatives (including the Preferred Alternative), a temporary haul road could be used over open water and intertidal marsh areas (black needlerush and smooth cordgrass) at the Bodie Island end of the proposed bridge. It would affect 6.0 acres (2.4 hectares) of jurisdictional communities (see Table 4-26), including 0.5 acre (0.2 hectare) of wetland black needlerush, 0.4 acre (0.2 hectare) of wetland maritime shrub thicket, 0.6 acre (0.2 hectare) of smooth cordgrass, and 4.5 acres (1.8 hectares) of open water habitat. Of the open water affected, 2.4 acres (1.0 hectare) would consist of SAV habitat. A survey conducted by NCDOT in the fall of 2007 confirmed that SAV distribution has not changed significantly since the figures produced in this report were calculated. However, patches of SAV move around from year to year, and may be present in more of the available habitat in the future. Dredging in the same area or a work bridge also could be considered.

Table 4-26. Temporary Impacts to Wetlands and Waters for the Parallel Bridge Corridor

Biotic Community	Impact in Acres (hectares)		
	Bodie Island Temporary Haul Road (All Parallel Bridge Corridor Alternatives)*	Hatteras Island Temporary Traffic Maintenance Road (Phased Approach Alternatives only)*	Total for Phased Approach Alternatives*

- Hectares were calculated from acres, thus minor rounding error exists when adding the individual hectare numbers.

*Includes the Preferred Alternative.

The two Phased Approach alternatives (including the Preferred Alternative) would include additional temporary impacts to wetland habitat resulting from construction of a temporary traffic maintenance road within the existing NC 12 easement on Hatteras Island (see Table 4-26). These impacts would not occur with the other Parallel Bridge Corridor alternatives, but would be identical for the two Phased Approach alternatives. The combined temporary impact of the Phased Approach alternatives (including the Preferred Alternative) on Bodie Island and Hatteras Island would be 12.5 acres (5.0 hectares), including 7.1 acres (2.9 hectares) of wetland and 5.3 acres (2.2 hectares) of open water. These impacts would include 2.1 acres (0.8 hectare) of CAMA coastal wetlands (smooth cordgrass and black needlerush). The temporary construction impacts for the Phased Approach alternatives (including the Preferred Alternative) are shown in Table 4-26.

No practicable alternatives exist that avoid impacts to Section 404 and CAMA coastal wetlands because of the pervasive nature of the resource, although the alternatives under consideration vary in the amount of wetland impact. The Parallel Bridge Corridor with Road North/Bridge South Alternative would have by far the largest wetland impact of the alternatives under consideration. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would have among the least permanent jurisdictional impacts at 3.1 acres (1.3 hectares) of permanent fill, including 0.5 acre (0.2 hectare) of wetland and 2.6 acres (1.1 hectares) of open water (see Table 4-25). Where fill or pile placement is not required, the loss of flora and fauna associated with construction activity would be short-term. Also, the permanent loss of wetland habitat and function would be replaced through required compensatory mitigation. Mitigation is discussed in Section 4.7.10.

As with the Pamlico Sound Bridge Corridor, the bulk of the area affected by dredging would be unvegetated aquatic bottom. The dynamics of the project area suggest that the bottom sand would, however, replenish itself over time, and losses would be temporary and short-term. Dredging is not planned in areas containing SAV. However, turbidity and siltation induced by dredging could disturb SAV near the dredged channel.

4.7.4.3 Bonner Bridge Demolition and Removal

Wetland impacts associated with demolition and removal of Bonner Bridge would depend on which access technique is used. Three access scenarios for demolition may be considered: temporary haul road, dredged work channel, and temporary work bridge. A top-down approach probably would not be possible because the piles that make up Bonner Bridge's foundation cannot simply be broken off just below the existing ground line but must be removed to at least 25.0 feet (7.6 meters) below the mean low water elevation or possibly deeper, as requested by the USACE in a letter dated January 16, 2001 (see Appendix A).

If underlying marsh sediments are comprised of mineral deposits instead of organic muck or clay, a temporary haul road could be used through these areas with certain mitigation stipulations. If soils are organic muck or clay, a temporary work bridge would be used instead of a haul road through estuarine marsh and mudflat communities. Dredged work channels should be restricted to the open water or nearby unvegetated shallow water areas, where practicable.

Important considerations with respect to the three demolition options are:

- Temporary Haul Road. The effects of a temporary haul road would depend on the nature of the subsoil. If there is a substantial organic or muck layer beneath the marsh, the construction of a temporary haul road would cause permanent changes in the marsh resulting from consolidation and distortion of the subsoil. Changes in biodiversity, as well as organic

productivity, could be a direct result of the compaction and distortion of these marine sediments. In this location, however, the likelihood of there being a substantial area of organic material under the haul road is remote.

- Temporary Work Bridge. Although more expensive than a haul road, a work bridge could be used for demolition and removal. If, however, Bonner Bridge is to be used as part of an offshore reef, it might need to be dismantled in large pieces, requiring the use of much larger equipment than could be handled on a work bridge. With a work bridge, direct impacts to the marsh and mudflats would result from driven piles, but the cumulative cross-sectional area of these structural supports would be relatively unsubstantial. Furthermore, after removal of these structures, it is anticipated that tidal flux would mitigate any minor sediment disturbances. The shade effect from the temporary structure could affect some portions of the marsh community; however, any shade-effect to the vegetation in the underlying marsh declines and the vegetation would recover almost immediately following the dismantling of the temporary bridge.

- Dredged Work Channel. Dredging would be limited to the open water and adjacent shallow water areas adjacent to the navigation zone. Much of this area is exposed to the high-energy currents and eddies common to Oregon Inlet. Sediments in these areas are shifting constantly so that little, if any, benthic community development occurs. However, bottom areas adjacent to Oregon Inlet would have increasingly developed benthic communities as the distance from the hyper-dynamic inlet increases. Dredging a channel in the high-energy portion of the channel and near-channel zones would have minor and short-lived effects on the biotic community resulting from sediment disturbances. Dredging activities in shallow water and marsh communities would be avoided because they would be much more disruptive to resident populations. Not only would all organisms, plant and animal, within the dredge zone be physically removed from the ecosystem, but any organism attracted to the re-sedimenting channel environment also would be removed during subsequent access channel maintenance activities. Substantial impacts would occur if dredging occurred within estuarine marsh and/or submerged aquatic communities where healing of the dredging "scar" would require a much longer recovery period than in open water. Though the long-term effects to community productivity would be minimal, the short-term effects would be relatively severe and would continue for an extended recovery period.

The FHWA and the NCDOT would coordinate with environmental resource and regulatory agencies prior to demolition and removal to determine the most practicable construction access methodology for the demolition of Bonner Bridge. Impacts for construction access would be determined and mitigated in full consultation with permitting agencies. A work bridge likely would be used over wetlands on Bodie Island for bridge demolition. Use of a temporary haul road could be requested if it is demonstrated that such access would not result in permanent impacts to marsh communities because these communities do not have underlying organic subsoil. This would be done if the cost of constructing and dismantling a temporary work bridge is so high that it would not be practicable to employ that methodology.

4.7.5 Unique and Rare Habitats

The Pamlico Sound Bridge Corridor would not result in permanent disturbance to Significant Natural Heritage Areas (SNHA) identified by the North Carolina Natural Heritage Program (NCNHP). SNHAs in the project area are the Refuge, dredge spoil islands used by nesting colonial waterbirds, and USFWS-proposed Wilderness areas. Permanent and temporary

disturbance to the Refuge, identified as a SNHA by the NCNHP and included on the Register of Heritage Areas (RHA) identified under the Nature Preserves Act, would result from the construction of any of the five alternatives within the Parallel Bridge Corridor.

4.7.5.1 Pamlico Sound Bridge Corridor

The Pamlico Sound Bridge Corridor would not result in permanent disturbance to SNHAs (see Figure 3-7) as identified by the NCNHP. The Pamlico Sound Bridge Corridor would not pass through the Refuge. All islands proposed for Wilderness status by the USFWS are along the soundside of the Refuge, east of the Pamlico Sound Bridge Corridor. The Pamlico Sound Bridge Corridor would pass within a quarter-mile (0.4 kilometer) of three SNHA dredge spoil islands: Sand Shoal Island, Island C, and Island B (see Figure 3-7). These islands have been historically important waterbird nesting areas. However, because of erosion, nesting no longer occurs on Island B or Sand Shoal Island, and they are primarily used by birds as intertidal foraging areas. Only Island C still supports waterbird colonies. Any construction-related disturbance to SNHAs would likely be in the form of temporary noise and, during nighttime work, light.

4.7.5.2 Parallel Bridge Corridor with NC 12 Maintenance

Permanent and temporary disturbance to the Refuge, identified as a SNHA by the NCNHP, would result from the construction of the Parallel Bridge Corridor. Based on the maintenance and relocation of NC 12 in the Refuge to the west and bridge construction, the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives would affect wetland biotic communities and the three manmade freshwater impoundments, which serve as important foraging and resting areas for migratory birds. The Phased Approach alternatives (including the Preferred Alternative) would place a bridge structure adjacent to the freshwater impoundments. Construction-related disturbances would likely be in the form of temporary noise and, during nighttime work, light. The areas of effect within the Refuge would be:

- Nourishment: 19.9 acres (8.1 hectares) primarily for dunes plus nourishment of 6.3 miles (10.1 kilometers) of the seashore within the Refuge;

- Road North/Bridge South: 93.4 acres (37.8 hectares) primarily for new 100-foot (30.5-meter) easement; and

- All Bridge: 92.2 acres (37.3 hectares) primarily for new 100-foot (30.5-meter) easement.

- Phased Approach Alternatives (including the Preferred Alternative): The total area of disturbance within the existing NC 12 easement in the Refuge would be 3.7 acres (1.5 hectares) permanent and 48.5 acres (19.6 hectares) temporary. With the Phased Approach/Rodanthe Nourishment Alternative, nourishment would occur on 1,500 feet (457.2 meters) of seashore within the Refuge.

The Parallel Bridge Corridor alternatives (including the Preferred Alternative) most likely would not affect the proposed Wilderness area of unnamed islands southwest of the southernmost freshwater pond and within 1.0 mile (1.6 kilometers) of Hatteras Island. The Oregon Inlet bridge in the Parallel Bridge Corridor would cross just east of the Oregon Inlet Shoal, which was recommended for Wilderness designation and is within the project area. The Parallel Bridge Corridor does not pass near the three SNHA islands: Sand Shoal Island, Island C, and Island B (see Figure 3-7).

4.7.6 Fisheries and Wildlife

4.7.6.1 Fish and Shellfish

Bridge construction over open water would disturb fish and shellfish resources in areas affected by pile placement and construction channel dredging. The temporary effects of channel dredging and jetting/driving pile placement would be similar. Both activities would generate a short-term increase in noise and turbidity. Noise from open water construction activity would be a temporary, localized disturbance to fish. Turbidity could result in a reduction in ecosystem productivity (i.e., ability of the system to produce and export energy) and nursery value by potentially covering shellfish beds within and near the corridor, eliminating organisms that cannot readily move, and displacing mobile organisms. Open water construction activities during the spring could also result in direct and indirect impacts on larval transport and migratory fish that use Oregon Inlet as a passageway to spawning grounds. The NCDOT would take practicable measures to minimize turbidity generated during bridge construction. Construction of the Pamlico Sound Bridge Corridor with either termini option would temporarily disturb fish and shellfish resources in areas affected by pile placement and channel dredging; however, non-mobile shellfish, such as clams and oysters, could suffer long-term impacts from construction-related dredging and siltation. The Parallel Bridge Corridor would have less of a construction impact on fish and shellfish communities because of less bridge construction over open water. The construction of the Rodanthe area bridge with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives could create a temporary disturbance for commercial crabbing and fishing operations within the Pamlico Sound; however, no long-term impact to commercial or recreational fishing is expected.

Pamlico Sound Bridge Corridor

Construction of the Pamlico Sound Bridge Corridor occurring in open water would disturb fish and shellfish resources in areas affected by pile placement (jetting and driving) and construction channel dredging. The Pamlico Sound Bridge Corridor would avoid the highly productive Walter Slough area behind Bodie Island, as well as scattered shellfish beds on the west side of the Refuge (see Figure 3-7). Also, the location and anticipated extent of dredging and disposal operations would not directly affect spawning or nursery areas. However, the Pamlico Sound Bridge Corridor would cross the northern end of Crab Slough, an area of high shellfish density (see Figure 3-7).

Potentially long-term impacts to finfish and shellfish also could result from bridge construction and dredging through the removal of benthic habitat, cover, and food sources. With the Pamlico Sound Bridge Corridor, bridge pile placement would permanently eliminate approximately 3 acres (1.2 hectares) of benthic habitat. The jetting-during-driving pile installation process would also temporarily alter benthic habitat, creating a zone of disturbance similar in diameter to the sub-surface length of the pile (see Section 2.10.1.3). The result could be possible elimination of non-mobile and slow-moving organisms and displacement of mobile organisms in the immediate vicinity of each pile. Opportunities to reduce the impact of jetting are discussed in Section 2.10.1.3. In the case of dredging, the displacement of mobile organisms would be temporary and any losses would be short-term because the spatial extent of dredging and construction at any given point in time would be limited, and many organisms can maneuver around unfavorable areas. An abundance of similar habitat is available and could provide the displaced mobile animals with suitable habitat to ensure their survival. However, non-mobile shellfish, such as clams and oysters, could suffer long-term impacts from construction-related dredging and siltation. In particular, Crab Slough is a shallow depth area of high oyster density that could be permanently altered by the mechanical disturbance of dredging and pile placement.

The construction of a bridge in the Pamlico Sound Bridge Corridor could create a temporary disturbance for commercial crabbing and fishing operations within the Pamlico Sound; however, no long-term impact to commercial or recreational fishing is expected. The bridge height is anticipated to accommodate current commercial and recreational vessel traffic. Also, the piles could be beneficial to fish populations by creating submerged structure that attracts fish. This could create the additional benefit of enhancing recreational fishing in the Pamlico Sound. Similarly, concrete from the demolished Bonner Bridge could be used to create artificial reefs, an important habitat to offshore fish and shellfish.

Parallel Bridge Corridor with NC 12 Maintenance

Construction of the Oregon Inlet bridge in the Parallel Bridge Corridor occurring in open water would disturb fish and shellfish resources in areas affected by pile placement and construction channel dredging in the area near Hatteras Island where the sand bars are rising. The construction of a Rodanthe area bridge with the Road North/Bridge South and the All Bridge alternatives could create a temporary disturbance for commercial crabbing and fishing operations within the Pamlico Sound; no long-term impact to commercial or recreational fishing is expected. The bridge height is anticipated to accommodate current commercial and recreational vessel traffic. Again, the piles could be beneficial to fish populations by creating submerged structure that attracts fish. Compared to the Pamlico Sound Bridge Corridor, open water construction with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be much more limited spatially and temporally.

The Parallel Bridge Corridor with Nourishment Alternative would include dredging and beach nourishment every four years (or use of USACE dredged material annually with the location of nourishment rotated so nourishment in any one location occurs only every four years) for the duration of the 50-year planning period. Direct dredging-related impacts on fish and shellfish include temporary changes in abundance and diversity during and immediately after dredging as well as potential entrainment in dredge equipment, especially of larval or post-larval fish and shrimp. Also, during dredging operations, fish and mobile shellfish could be displaced by turbidity and noise. However, the displacement would most likely be temporary and fish would return after dredging was completed. In the post-dredge period, some studies have found an increase in fish abundance at dredged sites (Saloman, 1974; Courtenay et al., 1980; Nelson and Collins, 1987), while others have found that dredging did not substantially change fish communities (USACE, 2001). However, if food resources are slow to recover or recover inadequately, long-term negative effects on fish and shellfish populations may result.

The effects of beach nourishment with the Nourishment Alternative on fish and shellfish would likely be similar to those of dredging. Individuals could avoid the replenished beach during periods of high turbidity, while less mobile species and larval fish may suffer mortalities. Prior research suggests that impacts to fish assemblages generally would be insignificant, but species specific impacts have been found (Wilber et al., 2003; Versar, 2004). The effects of beach nourishment would be temporary and localized; however, long-term-indirect impacts to feeding areas may result if benthic communities and primary productivity do not recover quickly or if the post-dredge habitat is of lesser forage quality compared to baseline conditions.

Mitigation measures for reducing dredging and nourishment impacts to fish and shellfish with the Nourishment Alternative include both restricting activity to winter months and avoiding dredging and beach nourishment during high recruitment periods, which for most species is spring and summer (Hobbs, 2002). Dredging effects could also be minimized by leaving patches undredged, thereby allowing individuals to recolonize quicker (Hobbs, 2002). A hopper dredge also could minimize impacts because it would not completely scour the bottom (Jutte et al., 2002). Hopper

dredging could, however, affect protected sea turtles, as discussed in Section 4.7.9.1. Other recommended dredging BMPs for reducing turbidity include the use of a hydraulic cutterhead dredge that operates below the channel surface, dredging during the incoming tide, silt curtains (Nightingale and Simenstad, 2001), temporary dikes (personal communication, July 8, 2005, John Fisher, PhD, North Carolina State University [NCSU]), modified operational controls, and modified heads.

4.7.6.2 Essential Fish Habitat

This section includes a summary of the findings of the *Essential Fish Habitat Assessment* (CZR, Incorporated, 2008).

Both replacement bridge corridor alternatives would produce turbidity, noise, and siltation resulting from construction, which in turn would create localized, short-term impacts to essential fish habitat (EFH) including estuarine emergent wetlands, oyster reef and shell bank, SAV beds, intertidal flats, and marine and estuarine water column. Although some small adverse impacts to EFH would occur during construction, the impacts would be temporary and are not expected to result in significant short-term or long-term adverse effects on managed species. Direct dredging-related impacts on marine EFH would result from noise and turbidity, sediment removal, and burial of organisms by fine sediments falling back to the sea floor. The result would be short-term adverse effects on biota and managed species that use benthic habitats, but long-term and permanent impacts to EFH and managed species are expected to be minimal. The extent of benthic community impacts are discussed in Section 4.7.6.4. If changes to benthic invertebrate communities do result, this does not necessarily mean EFH would be degraded or that negative impacts to managed species would result because most benthic communities are resilient and likely to recover quickly. Permanent loss or alteration of estuarine emergent habitat, seagrass, oyster reef and shell bank, and intertidal flats would result directly from shading and pile placement. Bridge and pile placement could result in several indirect impacts, including changes to: water flow; sediment grain size and topography; and light levels of the area underneath the bridge and for some distance surrounding the bridge. However, these changes are expected to have a minimal adverse effect on EFH and managed species (CZR, Incorporated, 2008). In the case of the two Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative), with shoreline erosion, parts of the bridge ultimately will be in the ocean.

Pamlico Sound Bridge Corridor

Impacts to EFH in the project area that would result from the construction of a bridge in the Pamlico Sound Bridge Corridor are presented in Table 4-27.

Turbidity, noise, and siltation resulting from construction would create localized, short-term impacts to estuarine emergent wetlands, oyster reef and shell bank, SAV beds, intertidal flats, and marine and estuarine water column. Permanent loss or alteration of estuarine emergent habitat, seagrass, oyster reef and shell bank, and intertidal flats would result directly from shading and pile placement. Potential loss of SAV was minimized by selection of a corridor that is in water greater than 6 feet (1.8 meters) in depth for approximately half its length. Using the most recent SAV mapping, it is estimated that pile fill with the Pamlico Sound Bridge Corridor alternatives would remove 0.3 acre (0.1 hectare) of SAV habitat. Permanent shading impact on SAV would be between 8.9 acres (3.6 hectares) and 9.2 acres (3.7 hectares) with the Pamlico Sound Bridge Corridor alternatives. SAV findings were based on available data.

Channel dredging required for the Pamlico Sound bridge construction would create temporary impacts. Using work bridges, rather than dredged channels (when possible and practicable), in

Table 4-27. Potential Construction Impacts to Inshore and Marine Essential Fish Habitat

Pamlico Sound Bridge Corridor		
Inshore EFH	**Bridge Construction**	**Dredging**
Estuarine emergent	Temporary disturbance; shading; some permanent loss from piles	None
Seagrass [1]	Temporary disturbance; shading; some permanent loss from piles	Temporary indirect disturbance; potential for some permanent loss because of turbidity and siltation
Oyster reef and shell bank[2]	Temporary disturbance; some permanent loss from piles	Removal in areas where this habitat is present; potential permanent loss of living beds through direct or indirect dredging impact
Intertidal flats	Temporary disturbance; some permanent loss of habitat from piles	Removal of sediment
Palustrine emergent and forested (freshwater wetlands)	Small loss of wetland maritime grassland	None
Estuarine water column (Pamlico Sound)[3]	Temporary increase in turbidity and decline in dissolved oxygen	Temporary increase in turbidity and decline in dissolved oxygen
Marine EFH	**Fill and Pile**	**Dredging**
Water column (Oregon Inlet)[4]	Potential temporary increase in turbidity in Oregon Inlet	Potential temporary increase in turbidity in Oregon Inlet
Parallel Bridge Corridor (Oregon Inlet and Rodanthe area bridges)		
Inshore EFH	**Bridge Construction**	**Dredging**
Estuarine emergent	Temporary disturbance; shading; some permanent loss from piles and temporary loss of habitat from construction of temporary haul road for the Oregon Inlet bridge	None
Estuarine shrub-scrub mangroves	None	None
Seagrass [1]	Temporary disturbance; shading; some permanent loss from piles	Temporary indirect disturbance; potential for some permanent loss because of turbidity and siltation
Oyster reef and shell bank[2]	Temporary disturbance; some permanent loss from piles	Removal in areas where this habitat is present; potential permanent loss of living beds through direct or indirect dredging impact
Intertidal flats	Temporary disturbance; some permanent loss of habitat from piles	Removal of sediment
Palustrine emergent and forested (freshwater)	Temporary disturbance; shading; some permanent loss from piles	None
Estuarine water column (Pamlico Sound)[3]	Temporary increase in turbidity and decline in dissolved oxygen	Temporary increase in turbidity and decline in dissolved oxygen
Marine EFH	**Fill and Pile**	**Dredging**
Water column (Oregon Inlet)[4]	Potential temporary increase in turbidity in Oregon Inlet with Oregon Inlet bridge	Potential temporary increase in turbidity in Oregon Inlet with Oregon Inlet bridge

[1]Also Habitat Areas of Particular Concern (HAPC) for summer flounder, red drum, and the snapper grouper management unit.
[2]Oyster reef and shell bank is also HAPC for the snapper grouper management unit.
[3]Pamlico Sound is also HAPC for Penaeid shrimp.
[4]Oregon Inlet is also HAPC for Penaeid shrimp, red drum, and the snapper grouper management unit.

areas of known SAV could minimize permanent loss of seagrass EFH. NCDENR Division of Marine Fisheries (DMF) maps do not indicate the presence of significant areas of shell bottom along the Pamlico Sound Bridge Corridor; therefore, dredging impacts to this habitat likely would be minor. However, permanent loss of EFH may result from dredging in sensitive oyster reefs like the northern end of Crab Slough (see Figure 3-7). Crab Slough is the only large oyster bed known to exist along any part of the Pamlico Sound Bridge Corridor. As seen on Figure 3-7, the Pamlico Sound Bridge Corridor would only cross the far northern end of Crab Slough and the crossing would be nearly perpendicular to the slough.

Parallel Bridge Corridor with NC 12 Maintenance

Impacts to EFH in the project area that would likely result from the construction of bridges in the Parallel Bridge Corridor also are presented in Table 4-27. Like the Pamlico Sound Bridge Corridor, turbidity, noise, and siltation resulting from construction would create localized, short-term impacts to EFH. Permanent loss or alteration of EFH would result directly from shading and pile placement. Using the most recent SAV mapping, it is estimated that pile fill would remove 0.2 acre (0.1 hectare), 1.4 acres (0.6 hectare), and 1.4 acres (0.6 hectare) of SAV habitat with the Nourishment, Road North/Bridge South, and All Bridge alternatives, respectively. The two Phased Approach alternatives (including the Preferred Alternative) would remove an estimated 0.2 acre (0.1 hectare) of SAV habitat. Again, using work bridges, rather than dredged channels (when possible and practicable), in areas of known SAV would minimize permanent loss of seagrass EFH. Permanent shading impact on SAV would be 1 acre (0.4 hectare), 7.3 acres (2.9 hectares), and 7.3 acres (2.9 hectares) with the Nourishment, Road North/Bridge South, and All Bridge alternatives, respectively. The Phased Approach Alternatives are estimated to include a permanent shading impact on SAV of 1 acre (0.4 hectare).

The Parallel Bridge Corridor with Nourishment would require dredging and beach nourishment every four years (or use of USACE dredged material annually with the location of nourishment rotated so nourishment in any one location occurs only every four years) for the duration of the 50-year planning period. Marine water column EFH in the vicinity of the offshore sand extraction and beach replenishment operations would be affected because these activities would generate turbidity and potentially low dissolved oxygen conditions. The direct effects of beach nourishment would be temporary and localized. However, long-term indirect impacts to marine EFH and managed species could result if the post-nourishment habitat is of lesser quality compared to baseline conditions (causing changes in sediment fill characteristics, beach morphology, and hydrology, properties that largely structure beach communities). Sediment grain size influences biogeochemical process, species biomass, and species diversity. Thus, changes in sediment could indirectly affect managed species by disturbing their habitat and food sources. For example, several studies suggest that recovery is rapid for most invertebrate species (reviewed in Greene, 2002); however, if poorly matched, silty fill material is used, recovery may take years and impacts could extend to adjacent off-shore areas (Green, 2002; Bilodeau and Bourgeois, 2004). Poorly matched fill impacts also would extend to microbial communities and primary producers, thereby affecting nutrient and organic matter processing and energy transfer to higher trophic levels. Similarly, adverse changes in beach morphology and hydrology can result in long-term loss of habitat value. Sandy beach species diversity is strongly related to Deans Parameter, a descriptive measure of beach profile. In general, narrow, steeply sloped, reflective beaches have much lower diversity than broad, gently sloping, dissipative beaches because of the presence of a large intertidal swash zone in the latter (Defeo and McLachlan, 2005; McLachlan and Dorvlo, 2005). Consequently, maintaining a gently sloping beach grade is essential to minimizing biological impacts, as increasing the beach slope will amplify wave energy on the beach, thereby creating a harsher swash zone environment and potentially decreasing species diversity (Speybroeck et al., 2006). NC 12 maintenance associated with other

Parallel Bridge Corridor alternatives (including the Preferred Alternative) may require some beach nourishment (see Section 4.6.8.6). However, sand mining and/or deposition of sand in aquatic environments is not anticipated to be necessary for NC 12 maintenance.

Once bridge piles are in the ocean because of shoreline erosion, the two Phased Approach alternatives (including the Preferred Alternative) could permanently affect diversity and density of some aquatic wildlife within these communities. Studies of oil and gas platforms and piers indicate that piles are typically colonized by a variety of sessile invertebrates such as mussels, barnacles, anemones, corals, bryozoans, and poriferans. This complex biogenic structure in turn attracts small mobile fish and invertebrates that in turn attract larger consumers (Nelson, 2003; Clynick et al., 2007). Research at oil platforms clearly shows that piles serve as fish aggregating structures (Stanley and Wilson, 2000). Davis et al., (1982) found fish and invertebrate communities changed substantially after platform installation, with some species disappearing completely and new species coming to dominate the assemblage. Similarly, in a study of artificial reefs constructed of piles, Ambrose and Anderson (1990) found some fish and invertebrate species increased in abundance while others declined. Because of habitat alteration and diminished vegetative growth, shading could impact managed species by locally diminishing the primary producers on which the managed species rely for food and cover, thereby resulting in an overall reduction in local carrying capacity. Fish abundance and growth have been found to be lower beneath fishing piers compared to adjacent waters (Able et al., 1998; Duffy-Anderson and Able, 1999). The high energy around the piles may reduce habitat quality for larval and adult fish, as well as reduce invertebrate species abundance and diversity. However, there are no known studies that have been conducted to document, prove, or disprove these potential effects.

Long-term permanent changes in surf zone community composition resulting from the two Phased Approach alternatives (including the Preferred Alternative) would not necessarily be detrimental to managed species. The introduction of bridge piles would provide a type of hard substrate previously unavailable in the surf zone, thereby increasing habitat complexity. In this way the bridge may act as an artificial reef, which, although different than the current habitat, should not be considered a loss or degradation of existing EFH. In addition, beaches are zonated with species abundance and diversity varying considerably from the high intertidal to subtidal zones (Defeo and McLachlan, 2005). It has been suggested that the natural assemblage of species found in areas where no hardened structures exist would not be displaced (personal communication, January 3, 2007, Dr. Thomas Lankford, University of North Carolina at Wilmington). Glasby and Connell (1999) reviewed studies of piles as artificial reefs and concluded that piles increase local species richness. For example, structure-oriented managed fishes, such as black sea bass, snapper grouper complex, and red drum, are likely to congregate at the bridge piles. However, the reef function of the bridge would evolve over time as the habitat in the vicinity of the piles shifts in response to natural erosion and water depths. Also, even by 2060, segments of the bridge structure will be in the shallow (6 to 10 feet/1.8 to 3.0 meters), high energy surf zone, which may not be suitable for managed reef associated species. In addition, Glasby and Connell (1999) emphasize that piles do not always support the same communities as natural marine hard substrate and should not be considered functionally equivalent to natural reefs.

Permanent loss or alteration of estuarine emergent habitat, seagrass, oyster reef and shell bank, and intertidal flats would result directly from shading and pile placement. In addition to direct loss of habitat, the Phased Approach/Rodanthe Bridge Alternative (Preferred) would result in the existence of 1.4 miles (2.3 kilometers) of bridge in the intertidal zone and an additional 8.0 miles (12.9 kilometers) of bridge in the surf zone by 2060. Bridge and pile placement could result in several associated impacts, including changes to water flow sediment grain size and topography; and light levels of the area underneath the bridge and for some distance surrounding the bridge.

An additional consideration is the long-term impacts resulting from potential maintenance activities for portions of the bridge that over time would be located in the surf zone. Although the impacts of solitary, over water construction events are often minimal, the Phased Approach alternatives (including the Preferred Alternative) would require periodic maintenance. Unlike much of the construction of the initial bridge on land, potential maintenance activities in the surf zone would occur over and/or in water and represent a long-term impact. However, maintenance activity will be undertaken in a way that minimizes impacts to EFH and managed species.

4.7.6.3 Effect of Alternatives on Commercial Fishing

Ongoing commercial fishing activity exists in the project area. The Pamlico Sound Bridge Corridor alternatives likely would not disrupt commercial fishing activity since the bridge structure will be in the sound where few commercial netting operations are conducted. Crabbing could be conducted regardless of the presence of bridge structure.

The Parallel Corridor with Nourishment, with All Bridge, and with Road North/Bridge South would most likely result in no change to commercial fishing compared to existing conditions. The two Phased Approach alternatives (including the Preferred Alternative) could result in some effect to inshore commercial fishing. As the shoreline erodes, the location of bridges associated with these alternatives would change relative to the beach so that by 2060 portions of these bridges would be beyond the off-shore breaker zone (see Table 4-10). Because of their location, there is the potential for the bridges to disrupt inshore commercial fishing operations by physically reducing potential trawling area and restricting net deployment. Although the Phased Approach alternatives (including the Preferred Alternative) could eliminate potential fishing areas in the vicinity of the bridge, impacts to overall commercial fishing operations would not be substantial as most fishing occurs further offshore and fishing area would be eliminated in only a small portion of the inshore.

4.7.6.4 Benthic Communities

Benthic communities would be affected primarily by fill impacts in open water (including SAV) and marsh communities (smooth cordgrass, black needlerush, salt flats, and brackish marsh). Both Pamlico Sound Bridge Corridor alternatives would result in pile fill of 2.7 acres (1.1 hectares) of open water and 0.3 acre (0.1 hectare) of SAV. Fill impacts to open water and marsh communities with the Parallel Bridge Corridor alternatives would be:

- Nourishment: 2.9 acres (1.2 hectares), including 2.6 acres (1.0 hectares) of open water and 0.3 acre (0.1 hectare) of marsh communities plus additional impacts associated with dredging for sand and then nourishment of 6.3 miles (10.1 kilometers) of the seashore within the Refuge;

- Road North/Bridge South: 39.2 acres (15.8 hectares), including 27.4 acres (11.0 hectares) of open water and 11.8 acres (4.8 hectares) of marsh communities;

- All Bridge: 7.9 acres (3.2 hectares), including 5.7 acres (2.3 hectares) of open water and 2.2 acres (0.9 hectare) of marsh communities; and

- Phased Approach Alternatives (including the Preferred Alternative): 3.0 acres (1.2 hectares), including 2.4 acres (1.0 hectare) of open water, 0.2 acre (0.1 hectare) of SAV, and 0.3 acre (0.1 hectare) of marsh communities (CAMA wetlands).

Pamlico Sound Bridge Corridor

With the Pamlico Sound Bridge Corridor, localized short-term impacts to benthic communities could result from all construction activity that occurs on estuarine or marine sediments. However, most benthic communities are resilient and likely to recover quickly. Bridge pile placement would permanently remove approximately 3 acres (1.2 hectares) of benthic habitat. Dredging of aquatic bottom would result in the removal of benthic habitat, resulting in localized losses of non-mobile organisms. Benthic loss would be minimal in the active Oregon Inlet area (since few species of organisms are capable of inhabiting this dynamic habitat) and greater in Pamlico Sound. Also, because of the many species-specific associations between invertebrates and SAV, measures taken to minimize SAV impacts could substantially reduce impacts to benthic invertebrates as well. In addition, it has been shown that benthic macroinvertebrates could recolonize dredged areas in a short time period after dredging ceases. Studies conducted in Hatteras Inlet during 1976 indicate that there is no apparent difference between benthic populations in a dredged channel and in natural, undredged channels, once the invertebrates have reestablished viable populations (Coastal Zone Resources Corporation, 1977). Thus, the loss of benthic organisms would most likely be temporary and short-term.

Parallel Bridge Corridor with NC 12 Maintenance

Construction of the Parallel Bridge Corridor occurring in open water (including Pamlico Sound, ponds in the Refuge, and Oregon Inlet) would disturb fish and shellfish resources in areas affected by pile placement, construction channel dredging, and a likely temporary construction haul road west of Bodie Island. Compared to the Pamlico Sound Bridge Corridor, open water construction with the Parallel Bridge Corridor would be much more limited spatially and temporally.

The Parallel Bridge Corridor with Nourishment Alternative would require dredging and beach nourishment every four years (or use of USACE dredged material annually with the location of nourishment rotated so nourishment in any one location occurs only every four years) for the duration of the 50-year planning period. The effect of offshore dredging on marine benthos has been studied extensively. Dredging would remove benthic organisms from the borrow site of sand removal. Many studies show a large initial decrease in abundance and biomass following dredging (Deis et al., 1992; Desprez, 2000; Guerra-Garcia et al., 2003). Effects are temporary, but recovery time varies by community composition, local physical conditions, and the season in which mining occurs (Hobbs, 2002; Diaz et al., 2004). Recovery of abundance and diversity can take three months to three years, and pre- and post-dredge species composition may display long-term differences (Jutte et al., 2002; Byrnes et al., 2004). Previous studies suggest that repeated dredging every four years (or less) may not allow benthic communities adequate time to recover.

Beach nourishment with the Nourishment Alternative would cover existing benthic organisms and create adverse water quality conditions in adjacent areas. Reduction in benthic macroinvertebrate abundance and diversity are often found (Reilly and Bellis, 1983; Rakocinski et al., 1996; Versar, Inc., 2004); however, when replenishment occurred in winter, no substantial effects were detected (Gorzelany and Nelson, 1987). Recovery time varies with species, the quality of sand, and time of year replenishment occurs (Rakocinski et al., 1996; Versar, Inc., 2004).

Mitigation measures for reducing dredging and beach nourishment impacts to benthos with the Nourishment Alternative include restricting activity to winter months and avoiding dredging and beach replenishment during high recruitment periods, which for most species is spring and summer (Peterson et al., 2000; Hobbs, 2002). One of the most important mitigation measures for beach replenishment is to replenish with sand similar to existing conditions. Dredging effects

also could be minimized by leaving patches undredged, thereby allowing individuals to recolonize quicker (Hobbs, 2002). Hopper dredging also may minimize impacts, because it does not completely scour the bottom (Jutte et al., 2002), although hopper dredging can adversely affect protected sea turtles (see Section 4.7.9.1). Other recommended dredging BMPs for reducing turbidity include silt curtains (Nightingale and Simenstad, 2001), temporary dikes (personal communication, July 8, 2005, John Fisher, PhD, NCSU), modified operational controls, and modified heads.

4.7.6.5 Biological Effects of Stormwater Runoff

Highway systems near water bodies may potentially contribute pollutants via stormwater runoff, road maintenance activity, litter, and atmospheric deposition. The primary pollutants associated with stormwater runoff are: heavy metals and organic compounds that may accumulate to toxic levels in aquatic organisms (e.g., Barwick and Maher, 2003); nutrients that lead to dissolved oxygen depletion (Rabalais et al., 2002); and particulates that often carry other pollutants into the environment (e.g., Basha et al., 2007). Pollutants associated with runoff also have the potential to effect terrestrial and avian species that feed in the effected aquatic environments (Thompson and Hamer, 2000). Without appropriate mitigation, water quality in receiving waterbodies could be diminished, increasing the potential for the project to impact managed species and their resources. Runoff from the Bonner Bridge is not captured and treated; therefore, the proposed project will not substantially change runoff in the vicinity of Oregon Inlet. Increases in impervious surface (as discussed in Section 4.7.2) that lead to increases in stormwater runoff have some potential to affect the aquatic environment; however, dilution of stormwater because of wave action and use of BMPs may serve to reduce negative impacts.

Section 4.7.2 describes the existing and future impervious surface associated with NC 12 in the project area, as well as characteristics of that runoff and how it would differ with each of the detailed study alternatives. Also as discussed in Section 4.7.2, NCDOT would incorporate BMPs for stormwater management into the project design.

4.7.6.6 Wildlife

A 3.9-million-mile (6.3-million-kilometer) network of public roadways covers approximately 1 percent of the United States, yet directly or indirectly affects wildlife in 15 to 20 percent of the total land area (Forman and Deblinger, 2000; Forman, 2000; Jackson, 2000; Forman et al., 2003). This results from what is known as the "road-effect zone" (Forman and Alexander, 1998; Forman and Deblinger, 2000). The road-effect zone is typically asymmetrical and represents the area extending outward along both sides of the roadbed in which substantial ecological effects are experienced. The extent and intensity of these ecological effects depends upon slope, wind, and habitat cover in relation to the roadbed (Forman and Alexander,1998; Forman and Deblinger, 2000; Coffin, 2007).

<u>Roadkill</u>

Because the Pamlico Sound Bridge Corridor is mostly a bridge over water, avian species are the most probable roadkill concern. The primary species that could be affected would be those that commonly perch on bridges such as gulls, terns, wading birds, pelicans, and raptors. For instance, substantial road mortality has been documented in royal terns (*Sterna maxima*; Bard et al., 2001) and brown pelicans (*Pelecanus occidentalis*; Owens and James 1991). It is unlikely that threatened or endangered species such as the piping plover would be subject to road mortality because of their behavior patterns. In the case of the Parallel Bridge Corridor alternatives (including the Preferred Alternative), small mammals, reptiles, amphibians, and avian species

could all be roadkill concerns. However, except for some rare species, road mortality has a minimal effect on animal populations (Forman and Alexander, 1998) despite it being a leading cause of mortality. In addition, some species seem to be capable of learning to avoid road mortality (Mumme et al., 2000; Coffin, 2007).

Noise Disturbance

Although evidence of wildlife population declines as a result of roadway mortality has persisted for years, the long-term effects of road avoidance resulting from traffic noise have only recently been actively studied. Traffic noise is a potential threat to an animal's health, reproductive success, physiology and behavior (Forman and Alexander, 1998; Radle, 2006). Road avoidance because of noise/human activity has been extensively documented for wildlife species such as black bears (*Ursus americanus*; Brody and Pelton, 1989), bobcats, (*Felis rufus*; Lovallo and Anderson, 1996), wolves (*Canis lupus*; Thurber et al., 1994), and songbirds (Reijnen et al., 1995; Reijnen et al., 1996; Forman and Alexander, 1998). Some species may become habituated to disturbance, but many species display reduced nesting and activity near areas of traffic noise (Fenandez-Juricic, 2001). Even though road noise has a varying effect on wildlife, it seems to substantially affect avian communities that utilize sound in their basic behaviors (Coffin, 2007). Noise levels as low as those found in a library reading room (42 to 48 decibels) have been found to negatively affect avian species (reviewed in Forman and Alexander, 1998).

The Pamlico Sound Bridge Corridor would be outside the Refuge, an area of concentrated use by waterfowl, wading birds, shorebirds, and various other wildlife species, removing the existing disturbance of NC 12 operations and maintenance from the Refuge. A bridge in this corridor could disturb birds using Pamlico Sound, such as waterfowl, but it would leave nesting birds largely undisturbed. The disturbance that would occur would be a new disturbance from both the perspectives of construction and operations.

A project in the Parallel Bridge Corridor could disturb avian nesting, resting, and foraging habitat (including the federally threatened piping plover), as well as nesting habitat for sea turtle species, both on the Bodie Island side of Oregon Inlet and on Hatteras Island within the Refuge. Disturbances occur today from traffic and NC 12 maintenance. Parallel Bridge Corridor Alternatives could alter that disturbance in the following ways:

- The All Bridge and Road North/Bridge South alternatives would move operational disturbances to the west, with the greatest change being at the north end of the Refuge in areas used most intensely by feeding birds. Construction noise also would occur in this westerly area with the greatest potential disturbance associated with the construction of bridges, particularly pile placement. These alternatives are not defined as phased in this FEIS and as such it would be expected that construction disturbance would occur over a three-year period throughout the Refuge.

- The Nourishment Alternative would reduce disturbances related to NC 12 storm maintenance by reducing the amount of maintenance required along the road and leave operational disturbances unchanged.

- The Phased Approach alternatives (including the Preferred Alternative) would remain in the existing right-of-way, leaving operational disturbances where they currently exist. As the shoreline erodes under the Phased Approach bridges, the Refuge wildlife habitat would move away from the bridge. The greatest new disturbance would come from bridge construction, particularly pile placement. As the project would be phased, the most intense construction disturbance would be confined to the location of the construction of any given phase.

However, the four phases would be built over an estimated 12.5 years of construction within a period of approximately 20 years, and movement of construction equipment and materials could be expected throughout the Refuge during the construction of each phase.

Direct Habitat Losses

Clearing within the construction limits of the replacement bridge corridor alternatives and subsequent fill placement could either eliminate or displace most biota. These activities would primarily affect animal communities of maritime shrub thickets. Typically, less mobile animals—such as small mammals, reptiles, and amphibians—would be lost with the removal of their habitat. More mobile animals, such as larger mammals and birds, might be able to move out of the area of impact. Survival of these displaced animals should be great considering the small area of habitat (7.8 to 9.8 acres [3.2 to 4.0 hectares]) that would be affected by the Pamlico Sound Bridge Corridor, as most of the bridge is over water. The Parallel Bridge Corridor would entail greater impacts to terrestrial communities with two alternatives because of the relocation of NC 12. The area of terrestrial habitat (upland and wetland) filled with each of the Parallel Bridge Corridor alternatives would be:

- Nourishment: 22.0 acres (8.9 hectares);
- Road North/Bridge South: 64.2 acres (26.0 hectares);
- All Bridge: 11.6 acres (4.7 hectares);
- Phased Approach/Rodanthe Bridge (Preferred): 13.6 acres (5.5 hectares); and
- Phased Approach/Rodanthe Nourishment: 6.9 acres (2.8 hectares).

Displaced animals might move temporarily or permanently to adjacent areas. However, this immigration could negatively affect or be prevented by adjacent wildlife communities that are already at carrying capacity. This impact could be mitigated in part by reclamation of habitat after removal of existing NC 12 pavement. With any of the alternatives, except the Nourishment Alternative, NC 12 pavement could be removed and replanted with native vegetation. This habitat may be of lower quality than natural habitat, but habitats on the Outer Banks are already subject to extensive disturbance, and many wildlife species there are capable of dispersing quickly into newly created habitat.

Effects of Construction Timing

Regardless of the alternative being considered, timing of construction would largely determine the level of disturbance that some wildlife experience. For instance, nesting birds are most sensitive to nesting disturbance during early nesting season (April-August), and sea turtles would be most sensitive to lighting and noise disturbance during nesting season (May-October). Night time construction also has more potential to disturb wildlife. Lighting is highly disorienting to sea turtles attempting to nest or to leave the beach after nesting or hatching (Witherington 1992; Witherington and Martin, 2000; Kikukawa et al., 1999). Light could also disturb roosting and migrating birds (Bruderer et al., 1999), which can reduce avian energy reserves if conducted during winter (Wiersma and Piersma, 1994). Therefore, impacts associated with the project would affect different species in different ways depending on the time of year and time of day that construction is conducted. Activities that disturb nesting (spring and early summer) should be considered the most detrimental because they could result in direct losses of potential young.

The Pamlico Sound Bridge alternatives would disturb fewer nesting species because construction would be conducted mostly out of wildlife nesting habitat.

4.7.6.7 Oregon Inlet Birds

Pamlico Sound Bridge Corridor

The Pamlico Sound Bridge Corridor would have minimal impact on the birds of Oregon Inlet because sensitive bird habitat was avoided whenever possible in selecting the location of the corridor. The sand flats at the southern tip of Bodie Island and the northern tip of Hatteras Island, frequently used by birds for foraging, resting, and sporadic nesting, would be avoided. In addition, the numerous dredged material islands used by colonial waterbirds for nesting are outside of the Pamlico Sound Bridge Corridor.

Most disturbances to birds would result from temporary construction activity, although fill and pile placement activity would entail a small but permanent loss of habitat used by a variety of birds. In a larger area, noise generated during construction activity also could displace birds inhabiting marsh habitat, primarily on Bodie Island where the Pamlico Sound Bridge Corridor would cross marsh for approximately 1,200 feet (366 meters). Also, because bridge construction would occur in the waters of Pamlico Sound, there is the potential for construction activity to disturb feeding and resting wintering waterfowl that migrate to the region every year. However, the disturbances would be localized and temporary.

Because the Pamlico Sound Bridge Corridor is mostly a bridge over water, avian species would be the most probable roadkill concern. The primarily species that may be affected are those that commonly perch on bridges such as gulls, terns, wading birds, pelicans, and raptors (see Section 4.7.6.6 under "Roadkill"). It is unlikely, that threatened or endangered species such as the piping plover would be subject to road mortality.

Parallel Bridge Corridor with NC 12 Maintenance

The Parallel Bridge Corridor could have minimal impact on the birds using Oregon Inlet, because sensitive bird habitat on the east side of Oregon Inlet Shoal was avoided whenever possible in selecting the location of the corridor. The beach and sand flats at the southern tip of Bodie Island and the northern tip of Hatteras Island, frequently used by birds for foraging, resting, and sporadic nesting, would be avoided by the Parallel Bridge Corridor. In addition, the numerous dredged material islands used by colonial waterbirds for nesting are outside of the Parallel Bridge Corridor. However, the Parallel Bridge Corridor with All Bridge and Road North/Bridge South alternatives could have moderate to substantial impact to the ponds and fields (brackish impoundments) in the Refuge used by migratory birds for nesting, foraging, and/or resting.

Like the Pamlico Sound Bridge Corridor, most disturbance to birds would result from temporary construction activity, although fill and pile placement activity would entail a small but permanent loss and/or degradation of habitat used by a variety of birds. In a larger area, noise generated by pile placement during construction activity also could displace some birds, primarily on Hatteras Island where the Parallel Bridge Corridor with All Bridge Alternative would relocate NC 12 on structure for approximately 7 miles (11.3 kilometers); however, avian response to construction activities has not been well studied and varies by species and site conditions. Also, because bridge and road construction would occur within the ponds of the Refuge with the Road North/Bridge South and All Bridge alternatives, there is the potential for construction activity to disturb feeding and resting waterbirds that regularly use the area. However, the disturbances would be localized and temporary.

The two Phased Approach alternatives (including the Preferred Alternative) include bridge construction over four phases, with construction in different parts of the Refuge, as described in Section 2.10. Thus, there would be four periods of construction disturbance of birds within the Refuge. Phase II would likely immediately follow Phase I for a construction period for the two phases totaling seven years. Phases III and IV likely would be 10 years each for a total construction period of 17 years with approximately a seven-year gap between Phases II and III and approximately a 10-year gap between Phases III and IV. The other Parallel Bridge Corridor alternatives analyzed would not be phased (see Section 2.10.2.5). Thus, construction noise disturbances in the Refuge would occur over a single construction period of approximately four years.

An additional factor to consider would be that of increased highway mortality for adults, hatchlings, and immature birds when a road or bridge is constructed through habitat they have always used for nesting, foraging, or resting. (Personal communication, Dennis Stewart, July 22, 2005, USFWS.) (See Section 4.7.6.6 under "Roadkill.")

Both Corridors

Although dredging would have little direct effect on the birds of Oregon Inlet, indirect effects could result if dredged material disposal techniques employed do not consider nesting activities of the colonial waterbirds. The terms and conditions outlined in the *Biological and Conference Opinion*s (USFWS, 2008) for the Phased Approach/Rodanthe Bridge Alternative (Preferred) related to piping plovers specify that "all dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission." The NCDOT is committed to implementing this measure. Numerous species depend on these dredge spoil islands, and their continued availability is critical. They also are heavily used during the non-breeding season. Species that nest on these islands include all of the coastal wading birds, royal terns, sandwich terns, brown pelicans, least terns, common terns, gull-billed terns, black skimmers, Caspian terns, and American oystercatchers. Oregon Inlet is heavily used by migrating and wintering piping plovers, and they frequent the dredge islands in the area as well. This area is also important to red knots since this species is being proposed for emergency listing (personal communication, December 2, 2006, Sue Cameron, North Carolina Wildlife Resources Commission [NCWRC]). Dredged material disposal islands near Oregon Inlet are experiencing severe erosion and, without further deposition of dredged material, some islands would likely disappear within a few years. Thus, properly controlled disposal of material could be beneficial by maintaining dredge spoil islands as viable nesting habitat. The effects of beach nourishment, including as a means for disposing of dredged materials, on nesting and migrating waterbirds also are a subject of interest and research. Recent studies conducted by the USACE have shown few substantial effects on shorebirds in North Carolina, but the ability to detect impacts is often difficult to determine on seasonal and highly variable waterbird populations (CZR Incorporated, 2003).

4.7.7 Positive Benefits of Allowing Natural Barrier Island Change

The positive benefit of allowing new inlets to remain, dunes to erode, storms to overwash the island, and washover deposits to remain in place is that this natural cyclic process is thought to preserve the barrier island system over time and despite sea level rise; however the island would not likely remain in its original location (e.g., island migration), configuration (e.g., number, location or size of inlets), or current vegetated state. Sediment pathways are restored, and new habitat is generated with each overwash cycle. Preventing the accumulation of washover fans, as is done by the human-made dune system in the project area, interrupts this process. Restoration

of the dune system after a storm involves artificially moving the sand seaward and reintroducing it into the beach/dune system. If the material is then removed seaward during later storms, it could be lost to the specific site as it moves downdrift. If in a later storm, the material is swept up again in an overwash event, the natural process is delayed by dune restoration but not prevented (Godfrey and Godfrey, 1976; Leatherman, 1988; Pilkey et al., 1998).

Habitats on the Outer Banks are highly ephemeral in nature because of the high level of natural disturbance present in barrier island ecosystems. Plants and wildlife such as seabeach amaranth and piping plovers have evolved to specialize in these habitats. Allowing natural barrier island change on Hatteras Island, which has been prevented in the project area by the presence of NC 12 and human dune building for many decades (including dune building by the CCC), as well as most recently by the closure of the breach formed at the southern end of the island during Hurricane Isabel, will allow the formation of ephemeral habitats that are essential to maintaining the natural ecological character of a barrier island. Overwash fans, new inlets, and low sloping beaches may be formed that serve as habitat for resting, feeding, and nesting of avian species.

The Pamlico Sound Bridge Corridor would allow the most natural barrier island change to occur. The Parallel Bridge Corridor Alternatives, except for the Nourishment Alternative, would allow for natural shoreline movement in most of the project area.

4.7.8 Impacts Prior to Implementation of Phases II to IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred) from Potential Short-Term or Emergency Actions

Prior to the completion of Phases II to IV of the Phased Approach alternatives (including the Preferred Alternative), maintenance of the existing NC 12 roadway within the existing NC 12 easement would be necessary in response to storms in order to allow continued travel along NC 12. Section 4.6.8.6 discusses the nature of these activities. These activities may disturb wildlife in the manner listed in Table 4-28. They also would affect habitat within the NC 12 easement in the areas in which they would occur (see Table 4-14 and Table 4-15). Continuation of these activities would interrupt natural shoreline processes with the loss of the benefits addressed in Section 4.7.7.

Table 4-28. Impacts of Storm-Related NC 12 Maintenance Activities on Natural Resources

Activity	Affect on Natural Resources	General Past Frequency of Events Necessitating Projected Activities
1. Road Scraping	Noise/vibration disturbance for wildlife. Lighting disturbance for sea turtles if conducted at night. Not likely to cause substantial impacts.	1 to 2 times per month
2. Dune Building and Maintenance in Easement	Noise/vibration disturbance for wildlife. Lighting disturbance for sea turtles if conducted at night. Not likely to cause substantial impacts.	2 to 3 times per year
3. Sandbag Dune Building and Maintenance in Easement	Noise/vibration disturbance for wildlife. Lighting disturbance for sea turtles if conducted at night. Not likely to cause substantial impacts.	1 to 2 times per year

Most NC 12 maintenance activities likely would result in few impacts to fish and wildlife. All activities are a potential noise/vibration disturbance; and, if conducted at night, lighting from maintenance activities has potential to disturb nesting sea turtles.

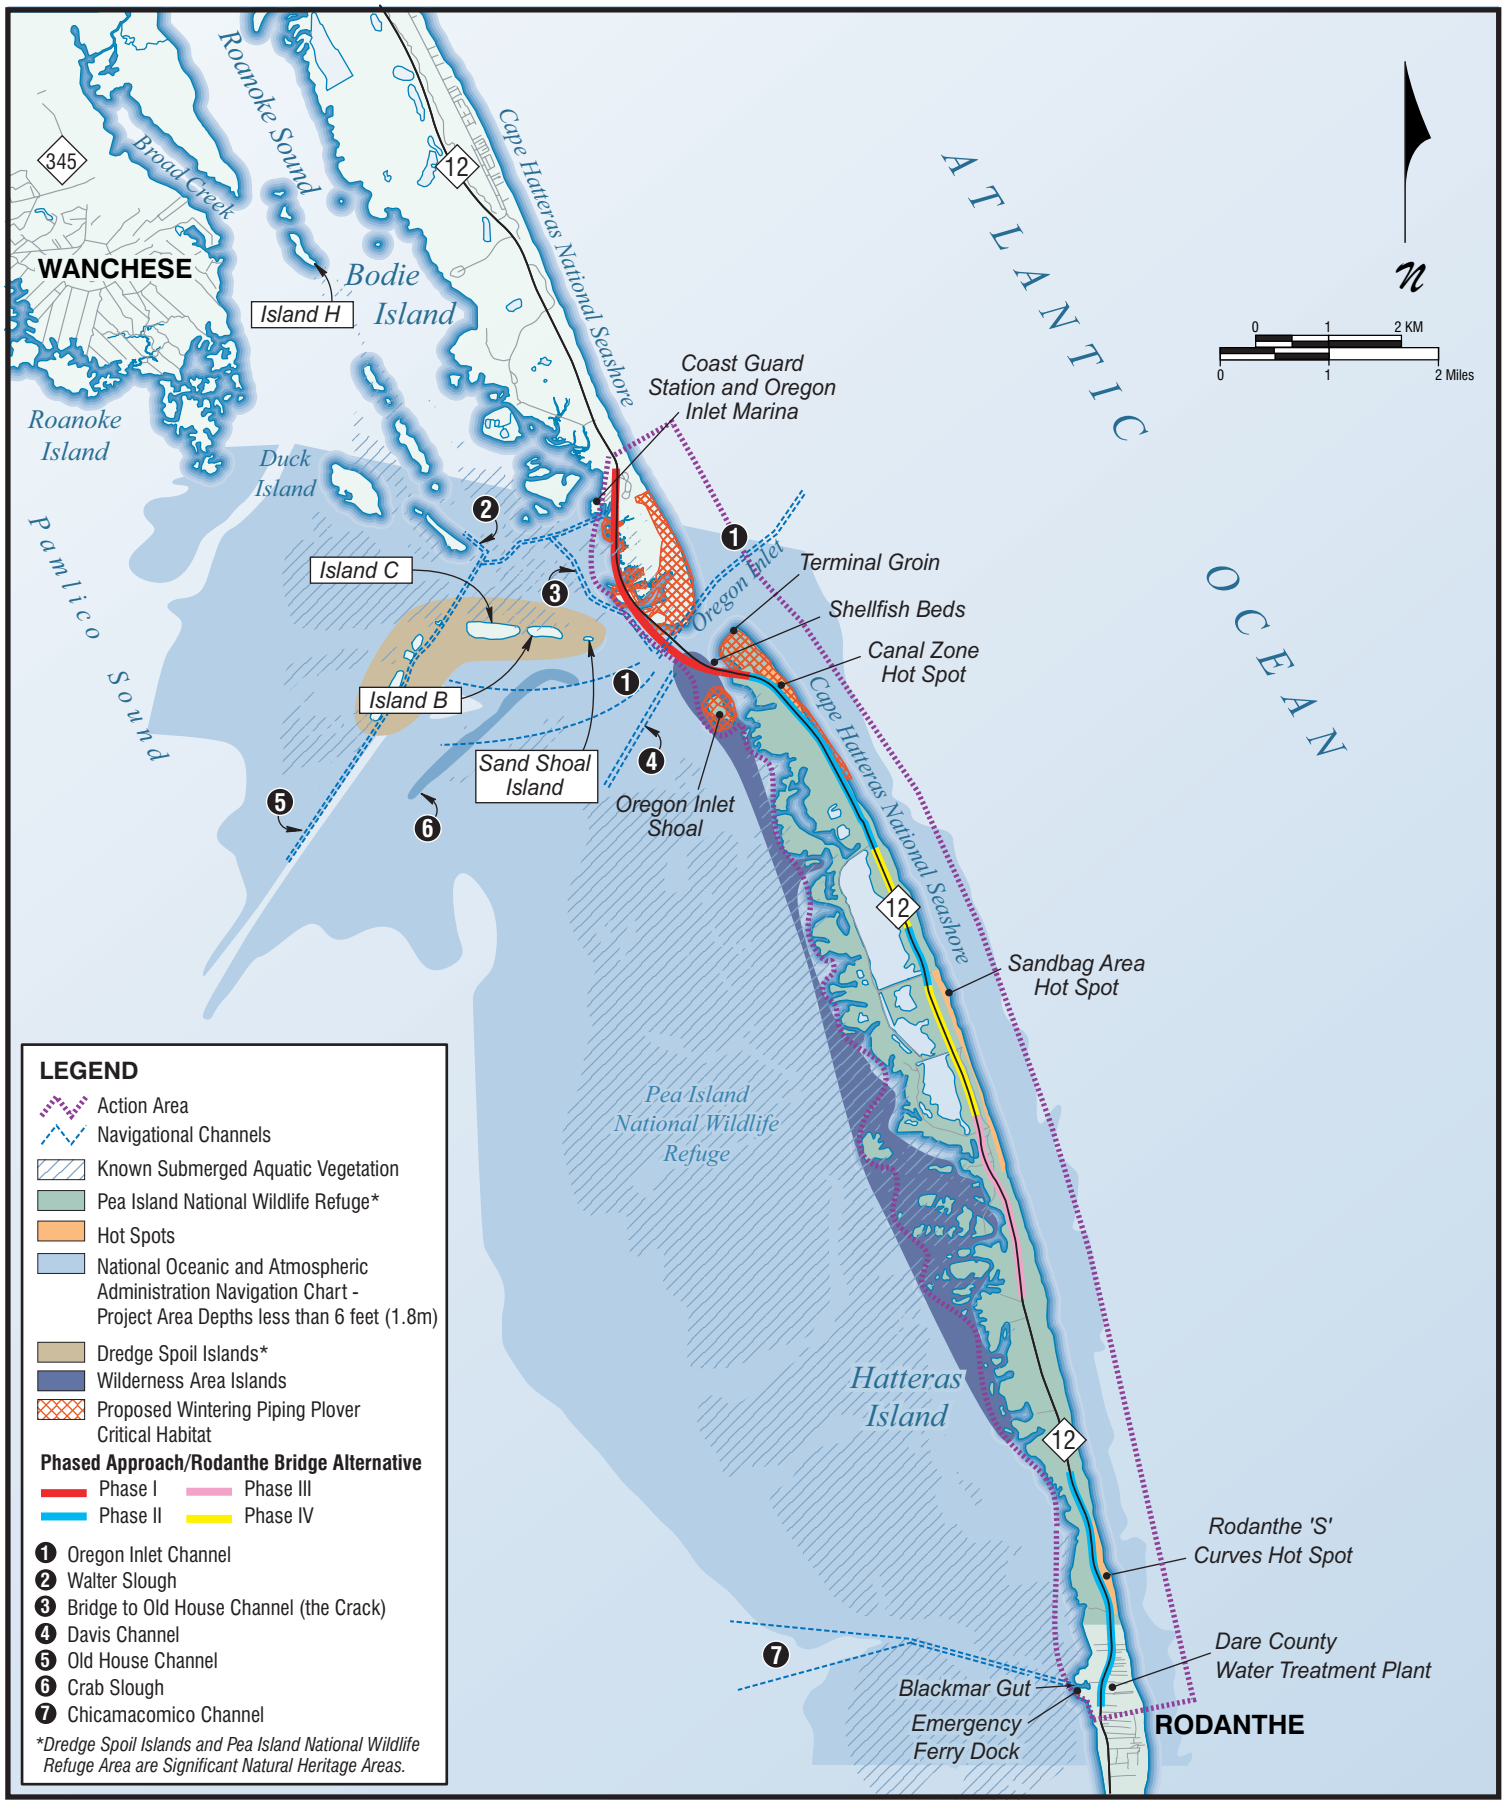

Table 4-14 and Table 4-15 indicate that the current level of NC 12 maintenance caused by storm damage would continue, and likely increase, in the three hot spot areas until Phase II is completed. Future maintenance would be confined to the existing NC 12 easement, since the Refuge has concluded that the selection of the Phased Approach/Rodanthe Bridge Alternative (Preferred) as the project for implementation in a ROD will preclude any future storm-related maintenance outside the NC 12 easement from being found compatible with the Refuge under the requirements of National Wildlife Refuge System Improvement Act of 1997. However, recognizing that the level of maintenance at the hot spots is not desirable, NCDOT intends to place a high priority on implementing Phase II, as discussed in Section 2.10.2.5. The completion of Phase II would substantially decrease the amount of storm-related maintenance on NC 12; however some would remain and may increase prior to the completion of Phases III and IV, though not to the extreme currently occurring in the three hot spots.

Also, as indicated in Section 2.10.2.5, NCDOT would not perform storm-related NC 12 maintenance work outside of the existing easement in the Phase III and IV areas, as well as in the 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge that is not expected to be threatened by erosion prior to 2060. Limiting the growth of NC 12 storm-related maintenance in the Phase III and IV areas to the extent practicable given the availability of transportation funding and the efficient use of those funds also is considered desirable by NCDOT. In order to help accomplish that objective, NCDOT would implement a monitoring program, the particulars of which would be developed in consultation with representatives of the Refuge. This program would include the development of decision-making criteria for translating monitoring findings into a decision to move forward with Phases III and IV.

4.7.9 Protected Species

The Pamlico Sound Bridge Corridor would not likely result in adverse impacts to the 13 federally-listed threatened or endangered species in Dare County. With the Pamlico Sound Bridge Corridor, the biological conclusion for 10 of these species is "May Affect – Not Likely to Adversely Affect," and the biological conclusion for three species is "No Effect." With the Parallel Bridge Corridor, the biological conclusion for six of these species (five species with the Nourishment and Phased Approach/Rodanthe Nourishment alternatives) is "May Affect – Not Likely to Adversely Affect," the biological conclusion for three species is "No Effect," and the biological conclusion for four species (five species with the Nourishment and Phased Approach/ Rodanthe Nourishment alternatives) is "May Affect – Likely to Adversely Affect." Possible effects on state-listed rare species, federal species of concern, and candidates for federal listing are discussed in Section 3.7.7. Section 7 (of the Endangered Species Act of 1973) formal consultation for these species is not currently necessary as they are not listed as a federally threatened or endangered species.

A *Biological Assessment* (FHWA and NCDOT, 2008) was submitted to the USFWS and National Marine Fisheries Service (NMFS) in March 2008 as part of Section 7 formal consultation for the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred). It addressed protected species within an action area shown in Figure 4-1. The USFWS subsequently

BIOLOGICAL ASSESSMENT ACTION AREA AND NATURAL RESOURCE-RELATED FEATURES

Figure 4-1

issued their *Biological and Conference Opinions* (USFWS, 2008) in July 2008 (see Appendix E). The USFWS concurred with the NCDOT's biological conclusions for the following protected species and indicated that these species would not be part of the formal consultation:

- West Indian manatee – May Affect, Not Likely to Adversely Affect;
- Roseate tern – May Affect, Not Likely to Adversely Affect;
- Seabeach amaranth – May Affect, Not Likely to Adversely Affect;
- Red-cockaded woodpecker – No Effect; and
- Red wolf – No Effect.

The *Biological and Conference Opinions* (USFWS, 2008) also indicated that the hawksbill sea turtle and Kemp's ridley sea turtle do not normally nest in North Carolina, but occur in waters off the North Carolina coast. Therefore, these two turtle species, along with the shortnose sturgeon, fall within the purview of the NMFS, so they also were not part of the formal consultation with the USFWS. The four protected species that the USFWS issued biological opinions on were piping plover, loggerhead sea turtle, green sea turtle, and leatherback sea turtle. In addition, the USFWS also issued a biological opinion for the proposed critical habitat for wintering piping plovers. As stated in the *Biological and Conference Opinions* (USFWS, 2008) (see Appendix E), the USFWS' biological opinion on these protected species was:

> "After reviewing the current status of the piping plover, loggerhead sea turtle, green sea turtle and leatherback sea turtle; the environmental baseline for the action area; and all effects of the proposed project, it is the USFWS's biological and conference opinion that the proposed replacement of the Bonner Bridge and subsequent phases of elevating portions of NC 12 onto bridges (Transportation Improvement Program [TIP] No. B-2500), as proposed, is not likely to jeopardize the continued existence of these species, and is not likely to destroy or adversely modify proposed critical wintering habitat for piping plover. No critical habitat has been designated for the loggerhead sea turtle; therefore, none will be affected. Critical habitat has been designated for the green sea turtle in Puerto Rico, and critical habitat has been designated for the leatherback sea turtle in the US Virgin Islands; however, this action does not affect these areas and no destruction or adverse modification of that critical habitat is anticipated."

The USFWS' *Biological and Conference Opinions* (USFWS, 2008) (see Appendix E) included the following Reinitiation/Closing Statement with respect to formal Section 7 consultation:

> "This concludes formal consultation on the action outlined in your March 5, 2008 request for formal consultation. As provided in 50 CFR section 402.16, reinitiation of formal consultation is required where discretionary federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

You may ask the USFWS to confirm the conference opinion as a biological opinion issued through formal consultation, if the critical habitat is designated. The request must be in writing. If the USFWS reviews the proposed action and finds that there have been no significant changes in the action as planned or information used during the conference, the USFWS will confirm the conference opinion as a biological opinion on the project and no further Section 7 consultation will be necessary."

The following section discusses in more detail the reasons for the biological conclusions for each federally-protected species with each of the proposed replacement bridge corridor alternatives (including the Preferred Alternative).

4.7.9.1 Federally-Listed or Proposed Species

Of the 13 federally-listed threatened or endangered species listed by the USFWS for Dare County (see Section 3.7.7), ten species were documented or may be present in the project area. The USFWS has jurisdiction over protected sea turtles species when they are on land. The NMFS has jurisdiction when they are in the water. The Pamlico Sound Bridge Corridor would not likely result in adverse impacts to any federally protected species. With all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative), a biological conclusion of "May Affect – Likely to Adversely Affect" was found for the green sea turtle, loggerhead sea turtle, leatherback sea turtle, and piping plover. In addition, a biological conclusion of "May Affect – Likely to Adversely Affect" was also found for the seabeach amaranth with the Nourishment and Phased Approach/Rodanthe Nourishment alternatives.

- **Bald eagle** (*Haliaeetus leucocephalus*) Federal Status – Delisted
  State Status – Threatened

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  Bald eagles were a federally-listed species (threatened), but have since been delisted in June 2007. Bald eagles, however, remain federally-protected under the Migratory Bird Treaty Act of 1918 and the Bald and Golden Eagle Protection Act of 1940 (BGPA). The BGPA prohibits take of bald and golden eagles and provides a statutory definition of "take" that includes "disturb." The bald eagle is a year-round transient species found regularly along the Outer Banks during migration and occasionally as a winter resident. The species has been sighted foraging over the ponds, marshes, open water, and sandy beaches of the area (Personal communication, July 25, 1990, Scott Lanier, USFWS). The abundance of suitable foraging habitat in the area and the transient nature of the bald eagle suggest that only temporary disturbances to the bird would be caused by construction activities. No eagles or eagle nests were observed during the field surveys of the project area in March 2003 and May/June 2004. Additionally, no trees of sufficient size to support a nest were observed within the project area. Any altered habitat resulting from bridge construction would be minimal and no substantial impacts are anticipated. The NCNHP has no records of any known populations of this species within the project area. Therefore, the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor would not likely adversely affect this species.

- **Red-cockaded woodpecker** (*Picoides borealis*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: NO EFFECT
  Parallel Bridge Corridor: NO EFFECT

  This species occurs in mature open pine forests in the southeastern United States, mostly longleaf pine forests. It prefers open longleaf pine savannas for foraging and nesting habitat. It excavates roosting and nesting cavities in live pine trees. The absence of mature stands of pine or pine-mixed hardwood limits its distribution. Suitable nesting or foraging habitat does not exist within one-half mile (0.8 kilometer) of the project area. Because of the lack of suitable habitat for foraging and nesting, this species would not be affected by the Pamlico Sound Bridge Corridor or by the Parallel Bridge Corridor.

- **Roseate tern** (*Sterna dougallii*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  This coastal bird prefers sandy, open beach and interdunal habitat. It typically nests colonially by forming depressions in the sandy substrate near grass clumps or other vegetation. Suitable habitat is available within the project area and records show documentation of the roseate tern within the project area (Mack, 1969). Solitary roseate tern nests have been sporadically reported in North Carolina; however, there is only one documented nest of this species from North Carolina and it was reported in Carteret County (Lee and Parnell, 1990). Appropriate nesting habitat for the roseate tern is available in the project area; however, the NCNHP has no records of any known populations of this species within the project area. The rarity of this species in North Carolina along with the absence of established nesting in the state make the possibility of roseate terns nesting in the project area very unlikely. The presence of the species in the project area mostly likely would be migrant birds seeking rest or food. Thus, the construction, operation, and existence of a bridge in the Pamlico Sound Bridge Corridor or the Parallel Bridge Corridor would not affect any nesting areas. Beach nourishment along the shoreline with the Parallel Bridge Corridor with Nourishment Alternative could potentially encourage future nesting species. No substantial impact would occur to the fishery resources upon which it depends during migratory periods. Therefore, the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor would not likely adversely affect the roseate tern.

- **Piping plover** (*Charadrius melodus*) Federal Status – Threatened
  State Status – Threatened

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – LIKELY TO ADVERSELY AFFECT

  This shore bird prefers open, sandy habitats, particularly those undergoing early succession. It is known to winter and nest on North Carolina beaches in which the nest is typically a hollow in the sand that may be lined with shells or pebbles. Two nests were found near

Bonner Bridge in 1996 surveys conducted by the NPS. NCWRC and NPS verified a single territorial pair at the southern end of Bodie Island in 2006. NCWRC also conducted a coast-wide wintering piping plover survey in January 2006 in which eleven piping plovers were found wintering at Oregon Inlet (personal communication, December 2, 2006, Sue Cameron, NCWRC). Oregon Inlet is heavily used by migrating and wintering piping plovers and they frequent the dredge islands in the area as well. Review of NCNHP maps indicated one known population of the piping plover within the northernmost portion of the Parallel Bridge Corridor area south of the terminal groin and west of the ocean shoreline. NPS has also confirmed that individuals from the federally-listed endangered Great Lakes population utilize the study area (personal communication, December 4, 2006, Karen Sayles, NPS).

The USFWS has proposed that the Oregon Inlet area on Bodie Island and some islands in Pamlico Sound be designated as critical habitat for wintering piping plovers. Although this habitat is not officially designated at this time, the piles of the bridge in the Parallel Bridge Corridor alternatives (including the Preferred Alternative) could directly use up to 0.05 acre (0.02 hectare) of critical habitat. The piles of the Pamlico Sound Corridor alternatives also could use this habitat, but to a lesser extent since the corridor is generally located further west.

Construction activities within the Pamlico Sound Bridge Corridor would affect less than 1 acre (0.4 hectare) of potential nesting or foraging habitat in the project area where sandy beaches and dunes have formed along the Pamlico Sound and along oceanic beaches. This effected dune area is near existing NC 12, and it provides little if any foraging or nesting habitat value. Since construction of the two Phased Approach alternatives (including the Preferred Alternative) would take place within the existing NCDOT easement, disturbance to potential nesting or foraging habitat in the project area would be minimal. However, construction noise/vibration could affect nesting, and shoreline erosion could create what could have served as Piping Plover habitat that would be instead shaded by the bridges as the shoreline erodes.

Beach nourishment along the shoreline within the Parallel Bridge Corridor with Nourishment Alternative and the Phased Approach/Rodanthe Nourishment Alternative could potentially encourage future nesting species. However, the inability to predict future nest locations, as well as the lack of information pertaining specifically to the effects of noise-related disturbances, leads to difficulty in drawing absolute conclusions. In addition, the dynamic nature of the Oregon Inlet area results in a continually changing distribution of suitable habitat that could require reevaluation in the future.

A Section 7 consultation was initiated for the Oregon Inlet bridge of the Parallel Bridge Corridor in 1997 after piping plovers nested in the Oregon Inlet area following the release of the 1993 DEIS. The consultation addressed piping plover feeding, nesting, and critical wintering habitat. Consultation to resolve the effect of the Preferred Alternative was initiated in March 2008 and completed with USFWS providing its *Biological and Conference Opinion*s (USFWS, 2008) document (see Appendix E). Since construction/demolition might result in a "take" of potential plover nests, the biological conclusion was determined to be "May Affect – Likely to Adversely Affect" for the Parallel Bridge Corridor alternatives (including the Preferred Alternative). Because construction and operation of the Parallel Bridge Corridor alternatives would have the potential to alter approximately 0.05 acre (0.02 hectare) of the proposed critical habitat north of Oregon Inlet, the effect on proposed critical habitat for wintering piping plovers was determined to be "May Affect – Likely to Adversely Affect" for the Parallel Bridge Corridor alternatives. Since the Pamlico Sound Bridge Corridor would avoid almost all piping plover habitat, a conclusion of "May Affect – Not Likely to Adversely Affect" was reached for this alternative.

Conservation measures and reasonable and prudent measures specified for the Phased Approach/Rodanthe Bridge Alternative (Preferred) by USFWS' *Biological and Conference*

*Opinion*s (USFWS, 2008) document (see Appendix E) are presented in Sections 4.7.10.4 and 4.7.10.5, respectively. They will be carried out by FHWA and NCDOT.

- **Hawksbill sea turtle** (*Eretmochelys imbricata*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  The hawksbill sea turtle occurs in tropical and subtropical waters of the Atlantic, Pacific, and Indian Oceans. Although this species is found along the eastern coast from Massachusetts southward, its nesting within the continental United States is limited to infrequent occurrences along the coast of Florida. Suitable habitat is available for the hawksbill sea turtle within the project area. However, the hawksbill is a highly tropical species that prefers the open ocean and has not been documented within the project area by the NCNHP (NCNHP database, 2003). Hawksbill turtle nesting in the United States is restricted to the southeastern coast of Florida and the Florida Keys, where they are nocturnal nesters (NMFS and USFWS, 1993). Because of the infrequent occurrence of this species within the project area and the absence of nesting activity, it is concluded that the proposed project would not likely adversely affect this species. This conclusion is affirmed in the USFWS' *Biological and Conference Opinion*s (USFWS, 2008) in Appendix E and in a letter from NMFS in Appendix A.

- **Kemp's ridley sea turtle** (*Lepidochelys kempii*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  This small Atlantic sea turtle species has been captured inadvertently in North Carolina waters numerous times, but is found typically along the Gulf of Mexico. It nests on tropical sandy beaches and is only an occasional visitor to North Carolina's marine waters. The NCNHP has no records of this species within the project area (NCNHP Database, 2003); however, open water in the Oregon Inlet area (ocean, inlet, and sound) can provide suitable habitat. Because of the infrequent occurrence of this species in the project area and the absence of nesting activity in North Carolina, it is concluded that the proposed project would not likely adversely affect this species. This conclusion is affirmed in the USFWS' *Biological and Conference Opinion*s (USFWS, 2008) in Appendix E and in a letter from NMFS in Appendix A.

- **Leatherback sea turtle** (*Dermochelys coriacea*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – LIKELY TO ADVERSELY AFFECT (land)
  MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT (aquatic)

  This species prefers the open ocean, preferably the warmer parts of the Atlantic Ocean; however, they occasionally forage in shallow bays, estuaries, and the mouths of rivers. It is

not known to nest regularly along the North Carolina coast and the NCNHP has no records of this species in the project area. Aerial surveys conducted between April and November in 1979, 1982, and 1983 revealed leatherback sea turtles near the ocean shoreline between Cape Hatteras, North Carolina, and Cape Sable, Nova Scotia (NMFS and USFWS, 1992). It is expected that occurrences of leatherback sea turtles in the ocean near the vicinity of the proposed project would be transients migrating between the nesting grounds in the Gulf of Mexico and cooler waters of the New England coast. Nests have been found only south of Cape Hatteras. However, open water in the Oregon Inlet area (ocean, inlet, and sound) does provide suitable habitat. Construction related noise/vibration and lighting could temporarily impact turtle nesting habitat with the Parallel Bridge Corridor alternatives (including the Preferred Alternative). With the two Phased Approach alternatives (including the Preferred Alternative), bridge and piles would eventually be on the beach or in the surf. The locations where this would occur would vary year-by-year along the bridge with the location and extent of beach erosion. The presence of a bridge piles on the beach and in the surf could reduce the quality of sea turtle nesting habitat by altering beach dynamics (wind/currents). Shading on the beach by the bridge could alter incubation periods and the ratio of male to female hatchlings. Because leatherback sea turtles have nested in North Carolina, it is concluded that the proposed project has potential to adversely affect this species on land. Therefore, the effect on the leatherback sea turtle with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) from the perspective of the jurisdiction of the USFWS is determined to be "May Affect – Likely to Adversely Affect." Since the Pamlico Sound Bridge Corridor would be in the sound and not on Hatteras Island, the effect of this alternative is "May Affect – Not Likely to Adversely Affect."

Conservation measures and reasonable and prudent measures specified for the Phased Approach/Rodanthe Bridge Alternative (Preferred) by USFWS' *Biological and Conference Opinion*s (USFWS, 2008) document (see Appendix E) are presented in Sections 4.7.10.4 and 4.7.10.5, respectively. They will be carried out by FHWA and NCDOT.

The effects on sea turtles while they are in the aquatic environment would be discountable. Turbidity, associated with construction, would be limited to dredging for barge access and pile driving. These activities would take place in a relatively small portion of Oregon Inlet at any one time, and would not limit travel by sea turtles between ocean and sound habitats. In addition, the presence of divers and barges would not represent a new disturbance to sea turtles because the area is already used by recreational users and boats. Also, it is unlikely that highway runoff would have a substantial negative affect on juvenile sea turtles. Stormwater runoff from bridges would be filtered by soil when over land, and could be diluted by wave action after Hatteras Island migrates westward. In the Phase II to IV area of the Phased Approach alternatives (including the Preferred Alternative), the potential for attraction of predatory fishes to newly created habitat (pilings) is unknown, but it is unlikely that these fishes would have a substantial effect on juvenile turtle populations because the pilings also would attract many species of prey fishes. Therefore, the effect on the leatherback sea turtle in the aquatic environment (jurisdiction of the NMFS) for all alternatives was determined to be "May Affect – Not Likely to Adversely Affect." A letter from NMFS affirming this conclusion is presented in Appendix A.

- **Green sea turtle** (*Chelonia mydas*) Federal Status – Threatened
  State Status – Threatened

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – LIKELY TO ADVERSELY AFFECT (land)
  MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT (aquatic)

  The green sea turtle is essentially a tropical species and does not breed in temperate zones, but it does occasionally occur in North Carolina waters during the warmer months. Green sea turtles occupy three habitat types: high-energy oceanic beaches that are used for nesting, convergence zones in the open sea that are used for migration, and benthic feeding grounds in relatively shallow, protected waters (NMFS and USFWS, 1991). The NCNHP has a record of this species nesting within the Parallel Bridge Corridor study area from 1980 (NCNHP Database, 2003). The known nesting site is along the beach east of the southern dike of the southernmost manmade pond within the Refuge. With the two Phased Approach alternatives (including the Preferred Alternative), bridge and piles would eventually be on the beach or in the surf. The locations where this would occur would vary year-by-year along the bridge with the location and extent of beach erosion. The presence of bridge piles on the beach and in the surf could reduce the quality of sea turtle nesting habitat by altering beach dynamics (wind/currents). Shading on the beach by the bridge could alter incubation periods and the ratio of male to female hatchlings. Because of the presence of nesting habitat and a known nesting site for the green sea turtle within the project area, impacts to this federally protected turtle from project construction noise/vibration and nighttime lighting could occur. Therefore, it is concluded that the proposed project has potential to adversely affect this species. Therefore, the effect on the green sea turtle with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) from the perspective of the jurisdiction of the USFWS is determined to be "May Affect – Likely to Adversely Affect." Since the Pamlico Sound Bridge Corridor would be in the sound and not on Hatteras Island, the effect of this alternative is "May Affect – Not Likely to Adversely Affect."

  Conservation measures and reasonable and prudent measures specified for the Phased Approach/Rodanthe Bridge Alternative (Preferred) by USFWS' *Biological and Conference Opinion*s (USFWS, 2008) document (see Appendix E) are presented in Sections 4.7.10.4 and 4.7.10.5, respectively. They will be carried out by FHWA and NCDOT.

  For the reasons discussed under the discussion of the leatherback sea turtle, the effects on the green sea turtle while they are in the aquatic environment would be discountable. Therefore, the effect on the green sea turtle in the aquatic environment (jurisdiction of the NMFS) for all alternatives was determined to be "May Affect – Not Likely to Adversely Affect." A letter from NMFS affirming this conclusion is presented in Appendix A.

- **Loggerhead sea turtle** (*Caretta caretta*) Federal Status – Threatened
  State Status – Threatened

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – LIKELY TO ADVERSELY AFFECT (land)
  MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT (aquatic)

  The loggerhead turtle is found in temperate and subtropical waters worldwide. It is fairly common along the coast of North Carolina and can be found from open to inland waters such as bays, salt marshes, and the mouths of large rivers, but it prefers open, pelagic habitat. Suitable nesting habitat for the loggerhead turtle exists within the Parallel Bridge Corridor project area. In North Carolina, these turtles nest on ocean-facing beaches along the Outer Banks from mid-May through the end of August. The NCNHP has noted all ocean-facing beaches within the project area as suitable nesting habitat. However, at the time of site reconnaissance in March 2003, May and June 2004, and November and December 2004, no current nesting sites or markers denoting current nesting sites were observed within the project area. With the two Phased Approach alternatives (including the Preferred Alternative), bridge and piles would eventually be on the beach or in the surf. The locations where this would occur would vary year-by-year along the bridge with the location and extent of beach erosion. The presence of bridge piles on the beach and in the surf could reduce the quality of sea turtle nesting habitat by altering beach dynamics (wind/currents). Shading on the beach by the bridge could alter incubation periods and the ratio of male to female hatchlings.

  The duration of the construction, while temporary, is of a long-term nature and bridge and road construction, nourishment, and associated activity, such as dredging and construction-related boat traffic, could harm sea turtles in the Pamlico Sound. The only type of dredge that is known to present a threat to turtles is the hopper dredge. Pipeline and clamshell dredges do not present a threat to turtles. (Dickerson et al., 1995; NMFS and USFWS, 1991; personal communication, April 8, 1997, Dave Nelson, Marine Biologist, USACE Waterways Experiment Station, Vicksburg, Mississippi; personal communication, May 2, 1997, Bill Adams, Planning Department, Environmental Resources Branch, USACE, Wilmington, North Carolina.)

  The loggerhead sea turtle periodically nests on stretches of open beaches of the project area from May 1 through November 15. Therefore, the effect on the loggerhead sea turtle with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) from the perspective of the jurisdiction of the USFWS is determined to be "May Affect – Likely to Adversely Affect." Since the Pamlico Sound Bridge Corridor would be in the sound and not on Hatteras Island, the effect of this alternative is "May Affect – Not Likely to Adversely Affect."

  Conservation measures and reasonable and prudent measures specified for the Phased Approach/Rodanthe Bridge Alternative (Preferred) by USFWS' *Biological and Conference Opinion*s (USFWS, 2008) document (see Appendix E) are presented in Sections 4.7.10.4 and 4.7.10.5, respectively. They will be carried out by FHWA and NCDOT.

  For the reasons discussed under the discussion of the leatherback sea turtle, the effects on loggerhead sea turtle while they are in the aquatic environment would be discountable. Therefore, the effect on the loggerhead sea turtle in the aquatic environment (jurisdiction of the NMFS) was determined to be "May Affect – Not Likely to Adversely Affect." A letter from NMFS affirming this conclusion is presented in Appendix A.

- **American alligator** (*Alligator mississippiensis*) Federal Status – Threatened (S/A)
  State Status – Threatened

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: NO EFFECT
  Parallel Bridge Corridor: NO EFFECT

  In North Carolina, American alligators are at the northern edge of its range. Although a resident of localized areas of mainland Dare County, most are found in the southeastern portion of the state, in lakes, swamps, marshes, and other fresh to brackish water coastal wetlands. Suitable habitat exists within the Parallel Bridge Corridor's project area in the wetland areas in the western portion of the Refuge, however, no alligators or nests were observed during field surveys within the project area. The NCNHP has no records of any known populations of the American alligator within the project area; therefore, the proposed project would not affect this species.

- **West Indian manatee** (*Trichechus manatus*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  In the United States, the manatee occurs primarily in Florida, although occasional occurrences during the summer have been documented as far north as coastal Virginia (USFWS, 1993). The water depth in the project area is deep enough to support habitat for the manatee. Manatees are reported as being sighted approximately 0.5 mile (0.8 kilometer) west of Rodanthe in the Pamlico Sound. Although manatees may move through Oregon Inlet to reach the waters of Roanoke and Pamlico Sounds, because of the extreme rarity of its occurrence in the area, the proposed project may affect but would not likely adversely affect this species. However, construction contracts would require compliance with the USFWS's *Guidelines for Avoiding Impacts to the West Indian Manatee: Precautionary Measures for Construction Activities in North Carolina Waters* (USFWS, June 2003).

- **Shortnose sturgeon** (*Acipenser brevirostrum*) Federal Status – Endangered
  State Status – Endangered

  Biological Conclusion:
  Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
  Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT

  Among the most primitive of the bony fishes, the shortnose sturgeon is an anadromous species that inhabits the lower sections of larger rivers and coastal waters of the Atlantic coast, moving into freshwater only to spawn in the spring. It occurs from the St. John River in New Brunswick Canada south into the St. Johns River in north Florida. Unlike other anadromous species, the shortnose sturgeon does not seem to make long distance offshore migrations.

  Historically the species probably occurred in major rivers throughout North Carolina, however, the current distribution is not well known. USFWS cites 2003 NC Natural Heritage Program data indicating records from 11 counties in North Carolina, not including Dare

County. There is, however, a record from 2006 in Pamlico Sound in Dare County (personal communication, November 30 2006, David Rabon, USFWS). A bottom dweller and benthic feeder, it prefers areas with soft substrate and vegetated bottom for most of the year. At spawning, the fish requires fast current and rough bottoms.

Suitable habitat exists within the project area and historic records document the species within Dare County. The rarity of occurrence in Albemarle and Pamlico Sounds, and because the fish prefer deep spots during the day and move to tidal flats for the night in the summer and early fall (Jackson et al., 1992), reduces the likelihood that the proposed project would adversely affect this species. In addition, any occurrence of this species within the project area would likely be short-term and in conjunction with annual spring migrations, further decreasing the likelihood that the project would adversely affect this species.

The variety of conservation measures that would be implemented to reduce potential impacts associated with sea turtles, also would serve as conservation measures to the shortnose sturgeon. However, because the shortnose sturgeon is rare in the action area, any effects from construction and lose of habitat will be discountable. Therefore, the effect of all alternatives on shortnose sturgeon has been determined to be "May Affect – Not Likely to Adversely Affect." A letter from NMFS affirming this conclusion is presented in Appendix A.

- **Red wolf** (*Canis rufus*) Federal Status – Experimental
  State Status – Significantly rare

Biological Conclusion:
Pamlico Sound Bridge Corridor: NO EFFECT
Parallel Bridge Corridor: NO EFFECT

Although once found throughout the southeastern United States, red wolves were extinct in the wild by 1980. Four pairs were released in the Alligator River National Wildlife Refuge in 1987. Pups and second-generation pups have been born in the wild, and the population has grown. Any heavily vegetated area of sufficient size to provide adequate food, water, and cover is considered potential habitat for the red wolf. They establish dens in hollow trees, stream banks, abandoned dens of other animals, drain pipes, and culverts. In Dare County, the red wolf occurs only on the mainland in large wilderness areas within the Alligator River National Wildlife Refuge. Suitable habitat does not exist in the project area; therefore, the proposed project would not affect this species.

- **Seabeach amaranth** (*Amaranthus pumilus*) Federal Status – Threatened
  State Status – Threatened

Biological Conclusion:
Pamlico Sound Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
Parallel Bridge Corridor: MAY AFFECT – NOT LIKELY TO ADVERSELY AFFECT
except for the Nourishment and the Phased Approach/Rodanthe Nourishment alternatives, for which the conclusion is MAY AFFECT – LIKELY TO ADVERSELY AFFECT

Seabeach amaranth is a fleshy stemmed annual herbaceous plant found on barrier island beaches and dunes. The flowering period is from June to frost. The sand flats and the foredune found in the Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor project areas offer suitable habitat for seabeach amaranth. Other habitats such as soundside beaches, foredune blowouts, and sand and shell material placed as beach nourishment, or dredge spoil

are also suitable habitat found within the project area of both replacement bridge corridors. This species was not documented from the project area prior to 2004, despite previous surveys over multiple years looking for this species. The NPS located a single amaranth plant on the Bodie Island flats, near Bonner Bridge on July 6, 2004. A complete survey was postponed because of nesting piping plovers; however, as a result of tropical storm events, the flats were washed out and no other plants were found associated with the sand spit. (Personal communication, November 19, 2004, Marcia Lyons, Cape Hatteras National Seashore.) Surveys for this species in 2006 did not document any plants within the Seashore or Refuge (personal communication, December 2006, Marcia Lyons, Cape Hatteras National Seashore).

Therefore, the effect on this species has been determined to be "May Affect – Not Likely to Adversely Affect" for all alternatives except the two involving nourishment. However, since the favored habitat is highly ephemeral, a survey of the project area could be conducted for the habitat of this species prior to potential disturbances from nourishment. If suitable habitat were found, a survey for the species would then be conducted. With the two detailed study alternatives that would involve nourishment, adaptation of that program to avoid impacts could be considered.

4.7.9.2 Federal Species of Concern

The Pamlico Sound Bridge Corridor and the Parallel Bridge Corridor would not adversely affect any federal species of concern and would not destroy substantial areas of habitat for these species. Table 3-25 lists the federal species of concern, their state status, and the existence of habitat within the project area.

Rafinesque's big-eared bat is not found in the project area, nor does suitable habitat exist in the project area for this species. The "Buxton Woods" white-footed mouse is primarily a resident of maritime forests in the Cape Hatteras area. The proposed project would not likely affect this species because it would not affect maritime forest. Maritime grasslands and maritime shrub thicket communities exist in the project area, and could serve as suitable habitat for "dune bluecurls;" however, it has not been documented north of Avon. Long-beach seedbox has been documented in Dare County along the margins of ponds in Buxton and in a roadside ditch near Wanchese. However, no survey has found these two plant species to exist in the project area; therefore, the proposed project is unlikely to directly affect these species. In addition, construction-related loss of habitat potentially used by "dune bluecurls" and long beach seedbox would be minimal.

The black rail and the northern diamondback terrapin are present in the project area and inhabit marsh communities, primarily along the sound. American eel also occurs throughout coastal North Carolina in fresh, brackish, and salt water bodies. Localized, short-term disturbance to habitat for these three species would likely result from construction activity in the replacement bridge corridors. However, considering the small loss or disturbance of habitat along the sound entailed by the replacement bridge corridors and the abundance of adjacent similar habitat in the project area, construction would not likely result in substantial adverse impacts to any of these three mobile species.

4.7.9.3 North Carolina-Listed Species

As indicated in Section 3.7.7.4, habitat exists in the project area for several state-listed species (gull-billed tern, peregrine falcon, bald eagle, saltmarsh spikerush, and possibly Carolina glasswort, blue witch grass, and small-flowered hemicarpha). The NCDOT would keep the NCNHP, the North Carolina Botanical Garden, the North Carolina Wildlife Resources

Commission, and/or other interested agencies informed regarding the status of the project. If any of these species were found to occur within the project area, the NCDOT would participate in the efforts of these agencies to design and implement a program to reduce potential effects.

4.7.9.4 Marine Mammals

Marine mammals are protected under the Marine Mammal Protection Act (MMPA). The MMPA prohibits, with certain exceptions, the "take" of marine mammals in US waters and by US citizens on the high seas, and the importation of marine mammals and marine mammal products into the US. "Take" is defined under the MMPA as "harass, hunt, capture, kill or collect, or attempt to harass, hunt, capture, kill or collect." The construction activities associated with the detailed study alternatives (including the Preferred Alternative) will not result in a "take" of marine mammals.

4.7.10 Avoidance, Minimization, and Compensatory Mitigation

This section describes mitigation options for the use of natural resources associated with the Pamlico Sound Bridge and the Parallel Bridge corridors. The CEQ has defined mitigation in its regulations (40 CFR 1508.20) as avoiding impacts, minimizing impacts, rectifying impacts, reducing impacts over time, and compensating for impacts. This section also includes information from the USFWS' Incidental Take Statement from the *Biological and Conference Opinions* (USFWS, 2008) (see Appendix E). The Incidental Take Statement applies to the federally-protected species that were part of formal Section 7 consultation and reflects the maximum potential take for each protected species that is authorized for the entire project over the proposed extended timeframe of the project.

4.7.10.1 Avoidance

Avoiding impacts is the preferred method of mitigation according to the CEQ (40 CFR 1508.20). Avoidance was taken into account during the corridor alternatives development studies for both the Pamlico Sound Bridge and the Parallel Bridge corridors. Wetlands are so pervasive in the project area that it is impossible to completely avoid some impact. Both the Pamlico Sound Bridge Corridor and Parallel Bridge Corridor, however, would avoid construction fill in emergent intertidal wetlands and the productive aquatic bottom of the Walter Slough area to the northwest. Also, two of the most notable avoidance measures were the decision to move the Pamlico Sound Bridge Corridor to a location west of the extensive SAV beds found behind Hatteras Island, and the decision to move its location outside the Refuge. These avoidance measures reduced impacts to wildlife communities, EFH, and important wetland habitats. Five Parallel Bridge Corridor alternatives (including the Preferred Alternative) were evaluated in detail in this FEIS partly in order to examine different wetland avoidance options.

The two Parallel Bridge Corridor alternatives that rely on nourishment (the Nourishment Alternative and Phased Approach/Rodanthe Nourishment Alternative) could fill large areas of intertidal beach during nourishment (76.51 acres and 13.8 acres [30.96 hectares and 5.58 hectares], respectively). However, beach nourishment occurs in an extremely ephemeral habitat; and, if done correctly, does not have long-term negative effects. In terms of impacts to other Section 404 jurisdictional areas, the Parallel Bridge Corridor alternatives may be listed in descending order as follows: Road North/Bridge South Alternative (78.15 acres [31.63 hectares]), All Bridge Alternative (12.33 acres [4.99 hectares]), Nourishment Alternative (4.28 acres [1.73 hectares]), Phased Approach/Rodanthe Bridge Alternative (Preferred) (3.11 acres [1.26 hectares]), and Phased Approach/Rodanthe Nourishment Alternative (3.08 acres [1.25

hectares]). Excluding intertidal beach, the Phased Approach/Rodanthe Nourishment Alternative would entail the fewest impacts to most Section 404 jurisdictional areas. However it is only slightly (0.03 acres [0.01 hectares]) less than the Phased Approach/Rodanthe Bridge Alternative (Preferred) and the lack of direct intertidal beach impacts would make the Preferred Alternative the least damaging to Section 404 jurisdictional areas.

4.7.10.2 Minimization

The locations of the Pamlico Sound Bridge and the Parallel Bridge corridors offer different levels of habitat and wetland avoidance, as described in Sections 4.7.3 and 4.7.4. The use of bridges over habitat and wetlands in place of a roadway on fill is one means incorporated in the alternatives to help minimize wetland impact. The beach nourishment included in the Parallel Bridge Corridor with Nourishment Alternative also would reduce wetland impact by allowing NC 12 to remain in its current location. Several additional measures would be used to minimize adverse impacts to natural resources:

- Conservation measures and reasonable and prudent measures specified for the Phased Approach/Rodanthe Bridge Alternative (Preferred) by USFWS' *Biological and Conference Opinion*s (USFWS, 2008) document (see Appendix E) would be implemented. They are presented in Sections 4.7.10.4 and 4.7.10.5, respectively.

- Work bridges, rather than dredging from barges (when possible and practicable), would be used for movement of construction equipment in areas where SAV is present. Work bridges also would be used to carry construction equipment over intertidal marsh areas (black needlerush and smooth cordgrass) at the Bodie Island end of the Pamlico Sound Bridge Corridor bridge. A temporary haul road likely would be used at the Bodie Island end of an Oregon Inlet bridge with the Parallel Bridge Corridor. Use of a work bridge instead of a haul road for short distances at critical locations, such as SAV locations, would be considered prior to construction.

- Depending on the particular construction activity being performed, turbidity curtains or other means of sediment and erosion control would be implemented in an effort to minimize impacts to adjacent areas of SAV and/or wetlands. Prior to construction, the design-build contractor would submit the proposed sediment and erosion control measures for each stage of construction to the NCDOT and the permitting agencies for review. The reviewing agencies may stipulate additional sediment and erosion control measures that would be followed accordingly.

- BMPs will also be implemented to manage pollutants associated with construction and operation activities to minimize the amount of pollutant loading that is discharged from the bridge and highway to the Oregon Inlet and Pamlico Sound. This could include development of an erosion and sediment control plan both to manage site erosion, sediment, and chemicals and to conduct land disturbance activities in a way that reduces erosion, contains sediment on-site during and after construction, prevents off-site transport of waste and chemicals, and minimizes use and production of pollutants.

4.7.10.3 Compensatory Mitigation

The 1990 Memorandum of Agreement (MOA) between the USACE and the USEPA states that "appropriate and practicable compensatory mitigation is required for unavoidable adverse impacts which remain after all appropriate and practicable minimization has been required."

Compensatory mitigation refers to the restoration, creation, enhancement, or preservation of wetlands as compensation for unavoidable wetland impacts. Guidance provided in the MOA indicates that restoration should be the first option considered and that on-site and in-kind mitigation is preferable to off-site and out-of-kind mitigation. The following mitigation ratio guidelines (ratio of the acres [hectares] of wetland replacement to acres [hectares] of wetlands permanently filled) are used by the USACE regulatory division in Washington, North Carolina:

- Restoration 2:1
- Enhancement 4:1
- Creation 3:1
- Preservation 10:1

In consultation with the other agencies, NCDOT may determine that there are circumstances where in-lieu-fee, fee mitigation, or other similar arrangements would serve as appropriate mitigation options. The *Ecosystem Enhancement Program* (EEP) could also serve as a potential in-lieu-fee source for compensatory mitigation.

Mitigation of Temporary Wetland Impacts

Construction equipment on land would be confined to the proposed right-of-way for the Pamlico Sound Bridge Corridor. Work bridges would be used over intertidal marsh areas (black needlerush and smooth cordgrass) at the Bodie Island end of the Pamlico Sound Bridge Corridor bridge to minimize potential temporary wetland impact.

With the Parallel Bridge Corridor, construction equipment would generally operate in the proposed right-of-way. A temporary haul road, however, could be used at the Bodie Island end of the Oregon Inlet bridge given the larger foundation components of the Oregon Inlet bridge. This activity would affect 6.0 acres (2.4 hectares) of wetlands. Construction of the two Phased Approach alternatives (including the Preferred Alternative) also would include traffic maintenance roads within the existing NC 12 easements on Hatteras Island, which would affect an additional 5.6 acres (2.3 hectares) of wetlands (see Table 4-26).

Temporary impacts to wetlands would be mitigated on a 1:1 basis by restoring these areas to their pre-construction condition. If needed, dredged materials could be used to return these wetland areas to their pre-construction elevation. Settling of the dredged materials would be taken into account in order to ensure a return to the proper elevation. These areas would be replanted immediately following the placement of dredged materials in order to provide rapid coverage and to prevent erosion. Species composition of the plantings would be based on pre-construction baseline data on species composition of the affected areas. Detailed monitoring of hydrology and vegetation would be conducted in order to ensure a return to full wetland function.

The USACE has successfully established salt marsh on dredge spoil deposited at proper elevations with complete vegetation coverage in three years (Broome, 1990). Woodhouse et al. (1972) also have successfully developed marshes on dredge spoil with complete coverage in two years. The USACE has developed guidelines for implementing salt marsh development on dredged material (USACE, 1978).

Mitigation of Permanent Wetland Impacts

Permanent wetland losses would be mitigated by restoring, creating, or enhancing wetlands at agency-approved ratios. Potential compensatory wetland mitigation includes on-site restoration and enhancement of in-kind wetlands as compensation for as much of the permanently affected area as possible; however, the limited availability of potential mitigation sites in the immediate vicinity of the project area would necessitate an exploration of additional options, which include off-site restoration, creation, and enhancement of wetlands.

Within the Pamlico Sound Bridge Corridor, permanent fill and pile placement would affect primarily man-dominated wetlands and maritime shrub thicket wetlands. Open water within the impoundments, salt shrub/grasslands, and black needlerush wetlands would be primarily affected by permanent fill and pile placement within the Parallel Bridge Corridor. Mitigation by wetland type would include:

- Wetland Maritime Shrub Thicket. Within the Pamlico Sound Bridge Corridor with either Rodanthe terminus option, less than 0.3 acre (0.1 hectare) of wetland maritime shrub thicket would be filled. Within the Parallel Bridge Corridor with any of the NC 12 Maintenance alternatives, less than 6.7 acres (2.7 hectares) of wetland maritime shrub thicket would be filled. These areas could be mitigated on an equitable basis by creating shrub thickets on land currently used for the Bonner Bridge approach on Hatteras Island. These areas are somewhat protected from salt spray and harsh winds. Once excavated and backfilled with organic material (to establish appropriate elevation and substrate) and planted with shrub species typical of adjacent shrub thickets, these areas eventually would develop into functioning maritime shrub thickets. If sufficient area is not available on Hatteras Island, several small shrub thickets exist adjacent to the man-dominated approach onto Bodie Island, and their habitat value could be enhanced by expanding this wetland community. If sufficient and suitable area still is not available on-site because of the high proportion of land that is wetlands, other options—including exchange (converting one wetland type to another wetland type of higher functional value in this case) and off-site mitigation—would be explored.

- Wetland Man-Dominated. Within the Pamlico Sound Bridge Corridor, Curved Rodanthe Terminus option, 1.2 acres (0.5 hectare) of man-dominated wetlands would be filled. With the Intersection Rodanthe Terminus option, 0.4 acre (0.2 hectare) would be filled. Within the Parallel Bridge Corridor, approximately 0.2 acre (0.1 hectare) of man-dominated wetlands would be filled with all three alternatives. These highly disturbed wetlands provide little value for animal communities; therefore, equitable mitigation options are numerous and are described later in this section.

- Wetland Maritime Grassland. Within the Pamlico Sound Bridge Corridor, approximately 0.5 acre (0.2 hectare) of wetland maritime grassland would be filled with both alternatives. Within the Parallel Bridge Corridor with Nourishment Alternative, 0.1 acre (0.04 hectare) of maritime grassland wetlands would be filled. With the Parallel Bridge Corridor with All Bridge Alternative, 0.2 acre (0.1 hectare) would be filled. A 0.3-acre (0.1-hectare) impact to maritime grassland wetland communities would occur with the Parallel Bridge Corridor with Road North/Bridge South Alternative. Within the Parallel Bridge Corridor with either Phased Approach alternative (including the Preferred Alternative), 1.3 acres (0.5 hectare) would be filled. Maritime grasslands are primarily transitional wetlands and are functionally less important than other emergent wetlands more common in the project area. Mitigation options are described later in this section.

- Wetland Salt Shrub/Grasslands. Pile placement with either terminus option of the Pamlico Sound Bridge Corridor would not affect this wetland community, which is normally found between small areas of salt marshes (smooth cordgrass and black needlerush) and the more stable maritime shrub thicket. With the Parallel Bridge Corridor with All Bridge Alternative, 2.6 acres (1.1 hectares) of wetland salt/shrub grasslands would be filled. A substantial impact (29.4 acres [11.8 hectares]) to salt shrub/grassland wetland communities would occur with the Parallel Bridge Corridor with Road North/Bridge South Alternative because of the relocation of NC 12. Within the Parallel Bridge Corridor with either Phased Approach alternative (including the Preferred Alternative), 1.6 acres (0.6 hectare) of wetland salt shrub/grasslands would be filled. The Parallel Bridge Corridor with Nourishment Alternative would not require impacts to this community. Salt shrub/grasslands are primarily transitional wetlands and are functionally less important than other emergent wetlands; however, the quality of this habitat has been enhanced within the project area through the use of prescribed burning. This increases foraging habitat for wildlife such as snow geese. (Personal communication, Dennis Stewart, July 28, 2005, USFWS.) Mitigation options are described later in this section.

- Wetland Reed Stand. Pile placement within the Pamlico Sound Bridge Corridor would not affect this wetland community because of its isolated location on the soundside of the Rodanthe area. The Parallel Bridge Corridor with Nourishment Alternative would affect 0.2 acre (0.1 hectare) of reed stand, whereas the Parallel Bridge Corridor with Road North/Bridge South Alternative would affect 0.9 acre (0.4 hectare). The Parallel Bridge Corridor with All Bridge Alternative would permanently affect 0.03 acre (0.01 hectare) of reed stand wetlands, primarily at the emergency ferry dock in Rodanthe. Within the Parallel Bridge Corridor with either Phased Approach alternative (including the Preferred Alternative), 0.6 acre (0.3 hectare) of wetland reed stand would be filled. Because of this community's encroaching nature, chemical spray treatment could be applied to potentially provide additional habitat for adjacent emergent marsh communities. These disturbed wetlands provide limited food resources for animal communities; therefore, equitable mitigation options are numerous and are described later in this section.

- Wetland Overwash. This community exists only within the Parallel Bridge Corridor; it consists of areas that have been recently overwashed from severe storm events, as well as areas in which NC 12 abuts the dunes, and sand removal from the roadway is performed on a regular basis. The Parallel Bridge Corridor with Nourishment Alternative would not affect this community. The Parallel Bridge Corridor with Road North/Bridge South Alternative would affect 1.5 acres (0.6 hectare) of overwash wetland fans, and the Parallel Bridge Corridor with All Bridge Alternative would affect 0.2 acre (0.1 hectare). Within the Parallel Bridge Corridor with either Phased Approach alternative (including the Preferred Alternative), 0.7 acre (0.3 hectare) of wetland overwash would be filled. This community is a transitional community and could be potentially restored by creating wetland shrub habitat or other similar grassland communities.

- CAMA Wetlands. Salt flat and brackish marsh wetland communities were identified within the project area; however, neither the Pamlico Sound Bridge Corridor nor the Parallel Bridge Corridor would affect these communities. Pile placement would fill less than 0.01 acre (0.01 hectare) each of black needlerush and smooth cordgrass communities with either terminus option of the Pamlico Sound Bridge Corridor. The Parallel Bridge Corridor with Nourishment Alternative would affect less than 0.3 acre (0.1 hectare) each of black needlerush and smooth cordgrass communities. The Parallel Bridge Corridor with Road North/Bridge South Alternative would substantially affect these communities (11.6 acres

[4.6 hectares] of black needlerush and 0.2 acre [0.1 hectare] of smooth cordgrass) because of the relocation of NC 12. Pile placement within the Parallel Bridge Corridor with All Bridge Alternative would affect approximately 2.2 acres (0.9 hectare) of these communities. Within the Parallel Bridge Corridor with either Phased Approach alternative (including the Preferred Alternative), 1.0 acre (0.4 hectare) of black needlerush would be filled. Both of these communities are considered areas of high value and are relatively scarce on a national basis. These wetlands would be mitigated or replaced in-kind. Mitigation options are described later in this section.

- Submerged Aquatic Vegetation Beds. Pile placement would fill approximately 0.3 acre (0.1 hectare) of SAV along the length of the Pamlico Sound Bridge Corridor. The Parallel Bridge Corridor with All Bridge and Road North/Bridge South alternatives would affect 1.4 acres (0.6 hectare) of SAV along the length of the Oregon Inlet bridge and the Rodanthe area bridge. The Parallel Bridge Corridor with Nourishment Alternative would affect 0.2 acre (0.1 hectare) of SAV because of the use of existing NC 12. Impacts from the construction of a temporary haul road to the west of the Oregon Inlet bridge would affect 2.4 acres (0.9 hectare) of SAV based on the most recent available survey data from the Division of Marine Fisheries. According to the USFWS Mitigation Policy, this highly productive, relatively scarce habitat must be mitigated for with no net loss of in-kind habitat value. Between 1985 and 1994, the Habitat Protection field office in Beaufort, NC, recommended seagrass mitigation for five permits which destroyed a total of 3.25 acres (1.32 hectares) of SAV. Compensatory mitigation for these permits totaled 4.74 acres (1.92 hectares) (Fonseca et al., 1998). Two of the five mitigation sites were evaluated and only one was judged successful. The difficulties associated with the creation of a functional SAV bed within a reasonable time suggest that avoidance is the best and most logical mitigative measure. This was accomplished for the most part by the placement of the Pamlico Sound Bridge and the Parallel Bridge corridors and the planned use of work bridges to carry construction equipment through SAV areas.

  Compensatory mitigation would involve planting and subsequent monitoring using recommendations provided by the National Oceanic and Atmospheric Administration (NOAA) (Fonseca et al., 1998). Mitigation site selection is critically important in the success of SAV mitigation. On-site mitigation is preferred, rather than the selection of an off-site location, since the historic presence of seagrass in the area of impact suggests a greater chance of replanting success (Fonseca et al., 1998). A four-year monitoring effort following planting or remedial replanting is recommended by the NOAA with success determination based on yearly documentation of: number of rhizome apicals, planning unit survival, shoot density, and aerial coverage of planning units. Prior to construction, mitigation options for SAV would be further evaluated after the NCDOT has completed a final SAV survey. The most recent NCDOT SAV survey was completed in 2007.

Mitigation considerations for individual wetland types were discussed above. Impacts to Section 404 jurisdictional wetlands will total 0.47 acre (0.19 hectare) for the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred). At a maximum mitigation ratio of 10:1, the Preferred Alternative would require 4.7 acres (1.9 hectares) of mitigation.

The Ballance Farm Mitigation Site is in Currituck County approximately 5 miles (8.0 kilometers) southeast of Moyock. The 430-acre (470-hectare) property was purchased by NCDOT to mitigate for wetland impacts associated with the widening of NC 168 (TIP Project No. R-2228) and future impacts in the Pasquotank River basin (High Unit Cost Grant Program [HUC] 03010205). The site originally consisted of 297 acres (120.2 hectares) of prior converted

agricultural fields along with existing tidal freshwater marsh and nonriverine forested wetlands. According to the Ballance Farm Mitigation Plan, implementation of the site was to provide marsh creation, marsh preservation, nonriverine wetland restoration, nonriverine wetland preservation and upland habitat preservation. After five years of monitoring, the nonriverine wetland restoration portion of the site was deemed successful and closed out in 2004. In 2005 a portion of the marsh creation site was deemed successful and accepted as suitable mitigation for TIP Project No. R-2228. The site was then transferred to the EEP as an asset.

Mitigation credit available from the Ballance Farm Mitigation could provide for all or a portion of the mitigation required for the Preferred Alternative. The amount of mitigation credit available from this site cannot be currently determined because other projects could debit credit from the site. Any mitigation not accounted for by the Ballance Farm would be reconciled through onsite mitigation and monetary contributions to the EEP.

4.7.10.4 Conservation Measures for Protected Species

Conservation measures represent actions, pledged in the project description, that the action agencies (FHWA and NCDOT) will implement to minimize the effects of a proposed action and further the recovery of the species under review. Such measures should be closely related to the action and should be achievable within the authority of the action agencies. Since conservation measures are part of a proposed action, their implementation is required under the terms of Section 7 consultation. Conservation measures for protected species were agreed to in formal consultation with USFWS and NMFS for the Phased Approach/Rodanthe Bridge Alternative (Preferred). The USFWS' *Biological and Conference Opinions* (USFWS, 2008) (see Appendix E) lists the following conservation measures:

- The Phased Approach/Rodanthe Bridge Alternative (Preferred) will allow natural shoreline migration and the formation of new inlet habitats to occur.

- The project will incorporate the most current BMPs to reduce habitat degradation from stormwater runoff pollution.

- Phase I of the project will be built at least 125 feet (38.1 meters) farther west of the Bonner Bridge and currently occupied piping plover habitat.

- NCDOT does not anticipate the use of explosives during construction or demolition of the existing bridge.

- The NCDOT contractor will use pipeline or clamshell dredging, rather than a hopper dredge to minimize effects to sea turtles.

- No permanent light fixtures will be installed on the bridge or the approaches (with the exception of navigation lights as required by the US Coast Guard).

- Seabeach amaranth surveys will be conducted at least one year prior to initiating bridge construction activities.

- Temporary facilities such as haul roads that affect proposed critical habitat will be removed as soon as possible.

Several additional conservation measures incorporated into the Phased Approach/Rodanthe Bridge Alternative (Preferred) are associated with species under the jurisdiction of the NMFS, including sea turtles (when in the ocean and sound) and the shortnose sturgeon. Additional conservation measures for the sea turtles will mainly involve measures to minimize impacts to water quality during demolition, construction, and maintenance. Although turtles are air-breathing reptiles and highly mobile while in the water, they could be temporarily affected by potential contaminants in the water column if they were in the vicinity. Minimization measures would include BMPs involving use, storage, and disposal of demolition/construction materials to minimize short-term turbidity or water quality degradation during over water construction in Oregon Inlet and during periodic maintenance. Stormwater management and controls would be designed with reference to NCDOT's BMP Toolbox and NCDENR's BMP Manual. Conservation measures to protect shortnose sturgeon would be similar to those protecting sea turtles, including no hopper dredging and BMPs to minimize habitat degradation during construction and periodic maintenance. In addition, construction and demolition activities associated with Phase I of the project would be completed as quickly as possible in order to minimize deterring spawning sturgeon from entering Oregon Inlet. Stormwater management and controls would be designed with reference to NCDOT's BMP Toolbox and NCDENR's BMP Manual.

NCDOT will comply with the NMFS's March 23, 2006, *Sea Turtle and Smalltooth Sawfish Construction Conditions* (NMFS, 2006) that restrict in-water construction-related activities when these protected species are observed in the project area. However, the NMFS and NCDOT agree that bridge construction or demolition activities do not need to stop when a protected species is sighted in the proximity of construction if the construction activities are not in the water. The in-water moratorium prohibits pile installation and removal, as well as activities associated with bridge construction and demolition when listed species are present, but does not restrict terrestrial activity.

4.7.10.5 Incidental Take Statement, Including Reasonable and Prudent Measures, for Protected Species

The material in this section was prepared by the USFWS and agreed upon by FHWA and NCDOT as it relates to protected species under the jurisdiction of USFWS that were the subject of formal Section 7 consultation. It is contained in the USFWS' *Biological and Conference Opinions* (USFWS, 2008) document (see Appendix E). Consultation with the NMFS resulted in their agreement for a biological conclusion of "May Affect – Not Likely to Adversely Affect" for species under its jurisdiction with the Preferred Alternative. Thus, an incidental take statement and reasonable and prudent measures beyond the conservation measures described in the previous section were not required or prepared by NMFS. The letter confirming the NMFS' conclusions is presented in Appendix A. This material applies to the Phased Approach/Rodanthe Bridge Alternative (Preferred).

Section 9 of the Endangered Species Act and federal regulations pursuant to Section 4(d) of the Endangered Species Act prohibit the taking of endangered and threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. Harm is further defined by the USFWS to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns such as breeding, feeding, or sheltering. Harass is defined by the USFWS as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of Section 7(b)(4) and Section 7(o)(2), taking that is incidental

to and not intended as part of the agency action is not considered to be prohibited taking under the Endangered Species Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and will be undertaken by FHWA so that they may become binding conditions of any grant or permit issued to NCDOT, as appropriate, for the exemption in Section 7(o)(2) to apply. FHWA has a continuing duty to regulate the activity covered by this Incidental Take Statement. If FHWA (1) fails to assume and implement the terms and conditions or (2) fails to require NCDOT to adhere to the terms and conditions of the Incidental Take Statement through enforceable terms that are added to the permit or grant document, the protective coverage of Section 7(o)(2) may lapse. To monitor the impact of incidental take, FHWA or NCDOT will report the progress of the proposed project and any impact on the species to USFWS.

Amount or Extent of Take Anticipated

The incidental take anticipated for piping plovers with the Phased Approach/Rodanthe Bridge Alternative (Preferred) is:

- Breeding Piping Plovers. USFWS expects incidental take of breeding plovers will be difficult to detect. The take would be the lost potential for nesting because of disturbance of breeding pairs at the nesting sites from nearby construction activity. It would be impossible to determine whether the lack of nesting or the absence of breeding pairs was because of the project or some other unrelated factor. It would only be possible to infer that the project directly caused the loss of a nest if an established nest was abandoned at the time construction began in the vicinity. Also, plover nests are cryptic and easily overlooked. However, this undetected level of take may occur near Oregon Inlet at historical nesting locations. Based on historical nesting data, the maximum level of incidental take is three breeding pairs per year precluded from nesting or caused to abandon nests during construction for Phases I and II of the Phased Approach/Rodanthe Bridge Alternative (Preferred) during each nesting season (i.e., April 1 to July 15) and the harassment of the associated breeding pairs.

- Migrating and Wintering Piping Plovers. USFWS expects incidental take of nonbreeding plovers with the Phased Approach/Rodanthe Bridge Alternative (Preferred) will be difficult to detect for the following reasons: sub-lethal effects are not easily determined; harassment which contributes to lessened survivorship may only be apparent on the breeding grounds the following year; and dead plovers may not be detectible. However, take of all migrating and wintering plovers throughout the extent of suitable habitat within the action area can be anticipated in all four phases of the Phased Approach/Rodanthe Bridge Alternative (Preferred) by the disturbance of feeding or roosting plovers from nearby construction activity.

The USFWS expects incidental take of all species of sea turtles will be difficult to detect for the following reasons:

- The turtles nest primarily at night and all nests are not found because (a) natural factors, such as rainfall, wind, and tides may obscure crawls and (b) human-caused factors, such as pedestrian and vehicular traffic, may obscure crawls;

- The total number of hatchlings per undiscovered nest is unknown;

- An unknown number of females may avoid the project beach and be forced to nest in a less than optimal area; and

- Lights may misdirect an unknown number of hatchlings and cause death.

However, take of all sea turtles throughout the extent of nesting habitat within the action area can be anticipated in all four phases of the Phased Approach/Rodanthe Bridge Alternative (Preferred) by harm or harassment because the effects of artificial light and disturbance from construction and future maintenance and repair activities on nesting females and hatchlings. Also, as portions of the beach migrate westward, take of all undetected nests throughout the extent of the nesting habitat can be anticipated from future maintenance or repair activities that may crush undetected nests. Finally, as portions of the beach migrate westward, take of all nesting sea turtles throughout the extent of nesting habitat within the action area can be anticipated from reduced nesting by females deterred by bridge piles on the beach and by shading effects on sex ratios of eggs in nests constructed underneath the bridges.

Effect of the Take

In its *Biological and Conference Opinions* (USFWS, 2008), the USFWS determined that this level of anticipated take is not likely to result in jeopardy to the species, or destruction or adverse modification of designated or proposed critical habitat.

Reasonable and Prudent Measures

The USFWS believes the following reasonable and prudent measures are necessary and appropriate to minimize take of the piping plover, loggerhead sea turtle, green sea turtle, and leatherback sea turtle. These nondiscretionary measures include, but are not limited to, the terms and conditions outlined in the *Biological and Conference Opinion*s (USFWS, 2008). They are:

- Piping Plover
  - Avoid disturbing nesting piping plovers.
  - To the extent possible, avoid disturbing foraging and roosting plovers.
  - To minimize the effect of harassment on foraging plovers, provide alternative foraging areas.
  - Avoid or minimize opportunities for avian predator perches.
- Sea Turtles - All Species
  - Avoid disturbing nesting sea turtles, nests, and hatchlings.
  - Educate construction contractors and pertinent NCDOT staff as to the adverse effects of artificial lighting on sea turtles.
  - Minimize the effects of construction lighting on nesting sea turtles and hatchlings.
  - Minimize the effects of vehicle headlights from the completed bridge.
  - Avoid permanent light fixtures.

Terms and Conditions

In order to be exempt from the prohibitions of Section 9 of the Endangered Species Act, NCDOT must comply with the following terms and conditions, which implement the reasonable and prudent measures described in the previous section. These terms and conditions are nondiscretionary, included as Project Commitments, and are:

- Piping Plover

    a. All construction equipment and personnel must avoid all bird closure areas within the Seashore and Refuge.

    All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 to July 15).

    All future repair work on bridge structures that would occur within or adjacent to current or future plover nesting areas must occur outside the nesting season (April 1 to July 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for nesting plovers and avoided to the extent possible.

    b. During the construction of Phases II, III and IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred), keep all construction equipment and activity within the existing right-of-way.

    Do not moor any construction barges within 300 feet (91.4 meters) of the following islands: Green Island, Wells Island, Parnell Island, Island MN, Island C, the small unnamed island immediately east of Island C, Island D, and Island G (see Figure 1 in the *Biological and Conference Opinion*s in Appendix E).

    c. All dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission. The point of contact is Sue Cameron at 910-325-3602. If the dredge material is used outside the current defined action area, the action area is assumed to be expanded to cover the beneficial placement of the material.

    d. To the maximum extent practical, while ensuring the safety of the traveling public, limit or avoid the use of road signs or other potential predator perches adjacent to plover nesting or foraging areas. Where signs or other structures are necessary, determine if alternative designs would be less conducive for perching on by avian predators (gulls, crows, grackles, hawks, etc.). For example, minimize or avoid the use of large cantilever signs in favor of smaller and shorter designs.

- Sea Turtles - All Species

    a. All construction equipment and personnel must avoid all marked sea turtle nests.

    Construction material and equipment staging areas must not be located seaward of the artificial dune.

All future routine maintenance activities of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the US Coast Guard), must occur outside the nesting season (May 1 to November 15).

All future repair work of bridge structures that would occur within or adjacent to current or future sea turtle nesting habitat, and which would require vehicles or equipment on the beach or the use of night lighting (excluding navigation lights required by the US Coast Guard) must occur outside the nesting season (May 1 to November 15) unless emergency or human safety considerations require otherwise. In this event, the area must be surveyed for sea turtle nests and avoided to the extent possible.

b. Provide an opportunity for the USFWS or an USFWS designee to educate construction contractor managers, supervisors, foremen and other key personnel and resident NCDOT personnel with oversight duties (division engineer, resident engineer, division environmental officer, etc.) as to adverse effects of artificial lighting on nesting sea turtles and hatchlings, and to the importance of minimizing those effects.

c. During turtle nesting season (May 1 to November 15), use the minimum number and the lowest wattage lights that are necessary for construction.

   During turtle nesting season, portable construction lighting must be of the low-pressure sodium-vapor type.

   During turtle nesting season, utilize directional shields on all portable construction lights, and avoid directly illuminating the turtle nesting beach at night.

   During turtle nesting season, all portable construction lights must be mounted as low to the ground as possible.

   During turtle nesting season, turn off all lights when not needed.

d. For Phases II, III and IV of the Phased Approach/Rodanthe Bridge Alternative (Preferred)**,** on the ocean side, design the bridge structure in a manner which will shield the beach on the east side from direct light emanating from passenger vehicle headlights. For the small portion of Phase I over land on Hatteras Island, retrofit the bridge structure at the time that Phase II connects with Phase I. The specific design of the bridge will be developed in consultation with the USFWS prior to re-evaluation of the environmental document for Phase II.

e. Avoid retrofitting the bridges and approach roads with permanent light fixtures in the future (excluding navigation lights required by the US Coast Guard).

Coordination of Incidental Take Statements with Other Laws, Regulations, and Policies

The USFWS will not refer the incidental take of any migratory bird for prosecution under the Migratory Bird Treaty Act of 1918, as amended (16 USC 703-712), if such take is in compliance with the terms and conditions (including amount and/or number) specified in the *Biological and Conference Opinion*s (USFWS, 2008).

Conservation Recommendations

Section 7(a)(l) of the Endangered Species Act directs federal agencies to use their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. The following non-binding conservation recommendations are discretionary agency activities recommended by USFWS in the *Biological and Conference Opinion*s (USFWS, 2008) to minimize or avoid adverse effects of the proposed project on listed species or proposed critical habitat, to help implement recovery plans, or to develop information:

- Piping plovers
  - FHWA and/or NCDOT could contribute funding to the current Seashore predator removal program or any future Refuge predator removal program.
  - The pond behind the terminal groin at the north end of Hatteras Island has historically provided foraging habitat for plovers whenever NCDOT has mined sand from it. NCDOT could continue to utilize this pond as a source of sand for construction/ maintenance purposes. NCDOT could remove the sand such that the elevation and shape of the mined area is restored to a moist/wet sand habitat conducive to plover foraging. This should be coordinated with the Refuge.
- Sea turtles – all species—FHWA and/or NCDOT could contribute funding to the Network for Endangered Sea Turtles (NEST), a nonprofit organization dedicated to the preservation and protection of sea turtle habitat in the Outer Banks from the Virginia border to Oregon Inlet. NEST monitors this area for nesting activity.

In order for USFWS to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, they requested notification on the implementation of any conservation recommendations. FHWA and NCDOT will consider implementation of these recommendations and notify USFWS should they decide to implement one or more of these recommendations.

4.8 Mineral Resources

There are no known mineral resources of economic value within any of the replacement bridge corridor alternatives.

4.9 Air Quality

A microscale air quality analysis was conducted to determine the potential effects of the replacement bridge corridor alternatives on local air quality. The "worst-case" project level carbon monoxide (CO) concentrations were determined for the existing (2002) and design (2025) years.

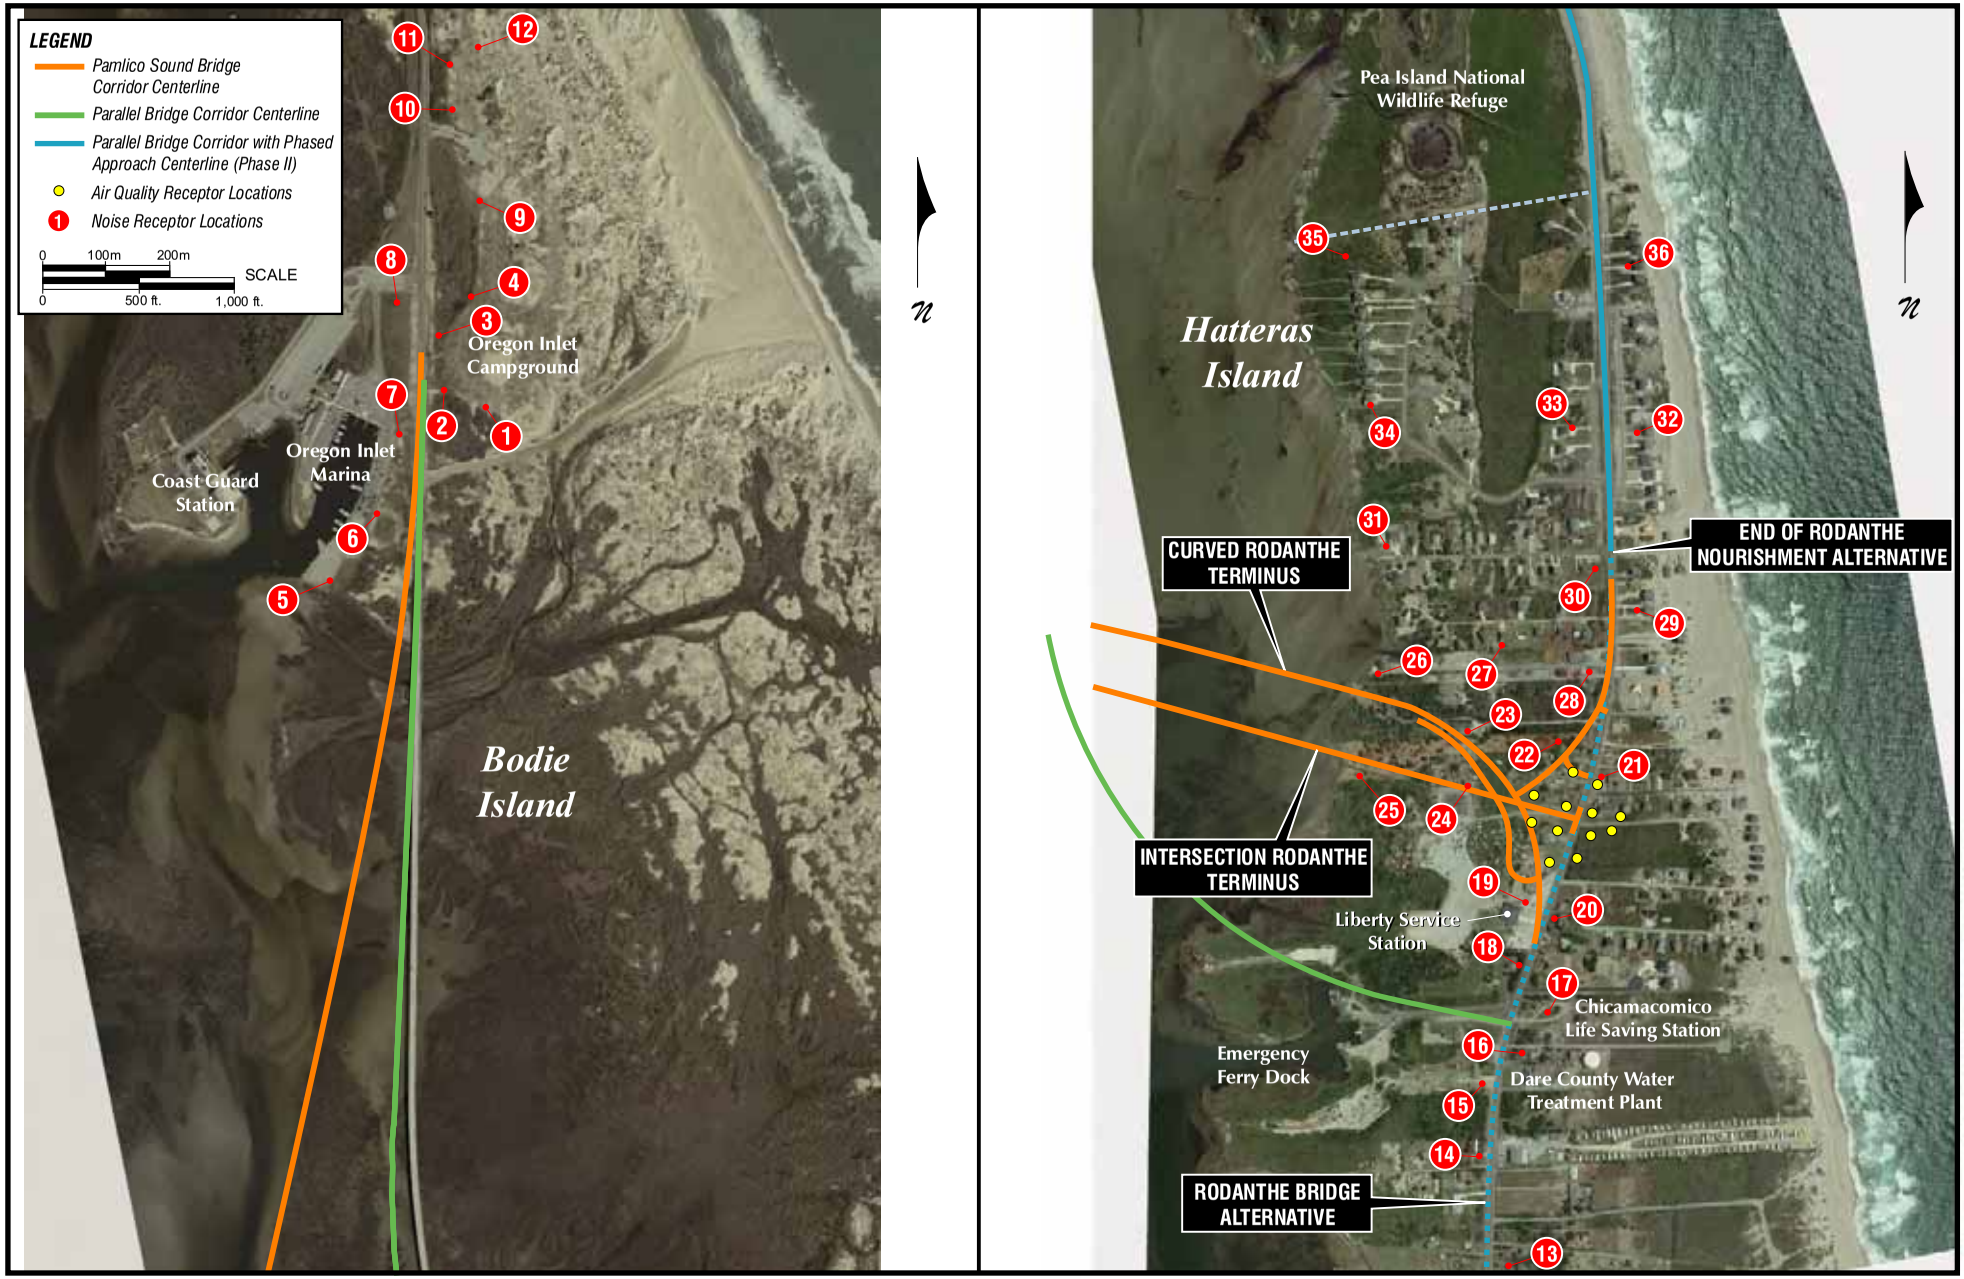
These CO concentrations were then compared to the National Ambient Air Quality Standards (NAAQS). The maximum one-hour and eight-hour CO levels predicted were below NAAQS maximum levels. Thus, the proposed project would not cause or exacerbate a violation of the NAAQS. The project conforms to the State Implementation Plan (SIP) and the goals set forth in the Clean Air Act Amendments (CAAA) and the Final Conformity Rule.

4.9.1 Regional Air Quality

The proposed project is included as part of a regional transportation network. The NCDOT's 2009 to 2015 TIP (NCDOT, 2008) includes the replacement of Bonner Bridge (TIP Project No. B-2500). The TIP is the basis for the area's regional emissions analysis, which utilizes vehicle miles traveled (VMT) (vehicle kilometers traveled [VKT]) and vehicle hours traveled (VHT) within the region to estimate daily pollutant burden levels. The results of this analysis determine whether an area is in conformity with regulations set forth in the Clean Air Act Final Conformity Rule.

The regional analysis performed for the TIP incorporates the effects of this project and would, therefore, satisfy the requirements set forth in the Final Conformity Rule.

4.9.2 Microscale Air Quality Analysis



A microscale air quality analysis was performed using the USEPA mobile source emission factor model (MOBILE 5B, the current model at the time of the preparation of the SDEIS) for vehicular emissions and the CAL3QHC version 2 air quality dispersion model for estimating pollutant concentrations near roadway intersections. Guidelines set forth in the USEPA's *Guidelines for Modeling Carbon Monoxide From Roadway Intersections* (USEPA, November 1992) and the NCDENR's *Guidelines for Evaluating the Air Quality Impacts of Transportation Facilities* (NCDENR, October 1999) were followed.

CO levels in the project area were estimated under worst-case conditions for existing traffic, traffic in 2025 assuming Bonner Bridge were to remain in place, and traffic in 2025 with the replacement bridge corridor alternatives. The No-Action Alternative assumes that Bonner Bridge is demolished at the end of its service life and not replaced. This likely would result in a dramatic but unknown decrease in traffic on NC 12, since limited ferry capacity would discourage visitors to Hatteras Island and future growth in the permanent population. Thus, No-Action Alternative CO levels could not be modeled for comparison with the replacement bridge corridor alternatives, as is customary for this type of analysis. CO levels were, however, modeled assuming 2025 traffic on NC 12 if Bonner Bridge were to remain in place.

The worst-case microscale CO analysis was performed for the peak one-hour traffic period. This peak period occurs on a Saturday during the peak tourist season. This period is when the greatest CO emissions are expected to occur.

The intersection of the Pamlico Sound Bridge Corridor's Intersection Rodanthe Terminus with existing NC 12 in Rodanthe as well as the comparable existing NC 12 intersection for the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives, has the potential for the greatest or worst-case CO concentrations. None of the other alternatives would introduce a turning movement into the main flow of NC 12 traffic. Twelve receptor locations were examined at this intersection (see Figure 4-2). The receptors were at locations where the highest CO concentrations could be expected and where the general public would have access. The 12 receptors were placed at various representative points near adjoining property lines where human activity might occur. Their locations were chosen in accordance with USEPA's *Guideline for Modeling Carbon Monoxide from Roadway Intersections* (USEPA-454/R-92-005).

The transport and concentration of pollutants emitted from motor vehicles are influenced by three principal meteorological factors: wind direction, wind speed, and the atmosphere's temperature profile. The values for these parameters were chosen to maximize pollutant concentrations at each receptor site to establish a worst-case situation.

AIR QUALITY AND NOISE ASSESSMENT LOCATIONS

Figure 4-2

The assumptions above presume the simultaneous occurrence of all worst-case parameters (peak-hour traffic conditions, an intersection with the greatest turning movements, low wind speeds, low atmospheric temperature, and worst-case wind direction). Thus, the CO levels estimated by the model are the maximum concentrations that could be expected to occur at each of the 12 receptors.

Model output provided peak 1-hour CO concentrations. Peak 8-hour concentrations were obtained by multiplying the highest peak 1-hour CO estimates by 0.61. This factor is recommended by the NCDENR's Division of Air Quality. It takes into account that over 8 hours (as distinct from a single hour) vehicle volumes fluctuate downwards from the peak, vehicle speeds vary, and meteorological conditions including wind speed and wind direction vary as compared to the very conservative assumptions used for the 1- hour levels.

The model predicts CO concentrations resulting from emissions from motor vehicles using roadways immediately adjacent to the location at which predictions are being made. A CO "background" level must be added to this value to account for CO entering the area from other sources upwind of the receptors. In consultation with the NCDENR's Division of Air Quality, a 1-hour value of 1.8 ppm and an 8-hour value of 1.1 ppm were used as background levels for this analysis.

4.9.3 Potential Air Quality Impacts

The highest 1-hour and 8-hour CO levels predicted at the 12 receptor sites are shown in Table 4-29. The CO levels shown include the modeled contributions of traffic plus the background concentration. The highest predicted 1-hour and 8-hour CO concentrations, 3.2 ppm and 2.0 ppm respectively, do not exceed the NAAQS of 35 ppm (1-hour) and 9 ppm (8-hour). The replacement bridge corridor alternatives would not cause or exacerbate a violation of the NAAQS.

Table 4-29. Predicted Worst-Case 1-Hour and 8-Hour CO Levels (ppm)

Category	Existing 2002	No-Action 2025	Worst-Case Location for the Replacement Bridge Corridor Alternatives 2025
1-Hour	2.4	2.6	3.2
8-Hour	1.5	1.6	2.0

National and state 1-hour standard = 35 ppm
One-hour values include 1-hour background = 1.8 ppm
National and state 8-hour standard = 9 ppm
Eight-hour values include 8-hour background = 1.1 ppm

4.9.4 Air Quality Conformance

The project is in Dare County, which has been determined to comply with the National Ambient Air Quality Standards. The proposed project is in an attainment area; therefore, Title 40 *Code of Federal Regulations* Parts 51 and 93 are not applicable. This project is not anticipated to create any adverse effects on the air quality of this attainment area.

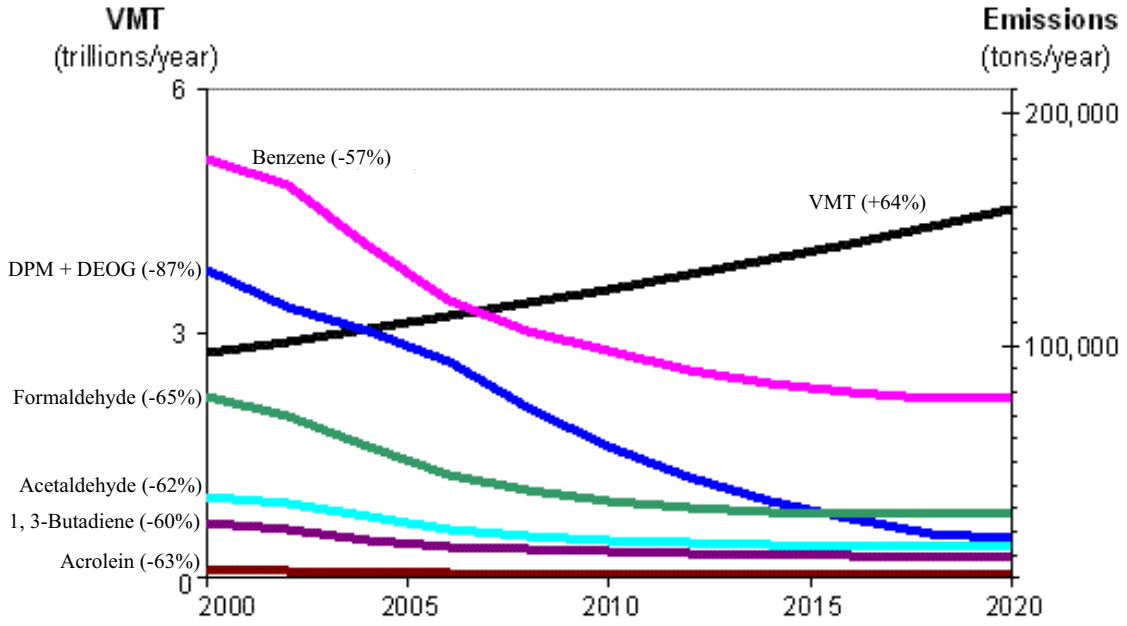
4.9.5 Mobile Source Air Toxics

In addition to the criteria air pollutants for which there are NAAQS (see Section 3.9), the USEPA also regulates air toxics. Most air toxics originate from human-made sources, including on-road mobile sources, non-road mobile sources (e.g., airplanes), area sources (e.g., dry cleaners), and stationary sources (e.g., factories or refineries). Because changes in vehicle-miles traveled associated with the replacement bridge corridor alternatives would be small, notable changes in the emission of Mobile Source Air Toxics (MSATs) are not expected with the replacement bridge corridor alternatives.

MSATs are a subset of the 188 air toxics defined by the Clean Air Act. MSATs are compounds emitted from highway vehicles and non-road equipment. Some toxic compounds are present in fuel and are emitted to the air when the fuel evaporates or passes through the engine unburned. Other toxics are emitted from the incomplete combustion of fuels or as secondary combustion products. Metal air toxics also result from engine wear or from impurities in oil or gasoline.

The USEPA is the lead federal agency for administering the Clean Air Act and has certain responsibilities regarding the health effects of MSATs. The USEPA issued a Final Rule on Controlling Emissions of Hazardous Air Pollutants from Mobile Sources (Volume 66 of the *Federal Register* on page 17229, March 29, 2001). This rule was issued under the authority in Section 202 of the Clean Air Act. In its rule, USEPA examined the impacts of existing and newly promulgated mobile source control programs, including: its reformulated gasoline (RFG) program; its national low emission vehicle (NLEV) standards; its Tier 2 motor vehicle emissions standards and gasoline sulfur control requirements; and its proposed heavy duty engine and vehicle standards and on-highway diesel fuel sulfur control requirements. Between 2000 and 2020, FHWA projects that involve even a 64 percent increase in VMT, will reduce on-highway emissions of benzene, formaldehyde, 1,3-butadiene, and acetaldehyde by 57 percent to 65 percent, and will reduce on-highway diesel particulate matter (PM) emissions by 87 percent, as shown in Table 4-30.

As a result, USEPA concluded that no further motor vehicle emissions standards or fuel standards were necessary to further control MSATs. The agency is preparing another rule under authority of Clean Air Act Section 202(l) that will address these issues and could adjust the full 21 and the primary six MSATs.



4.9.5.1 Unavailable Information for Project-Specific MSAT Impact Analysis

This document includes a basic analysis of the likely MSAT emission impacts of this project, including all the replacement bridge corridor alternatives assessed in the FEIS. However, available technical tools do not enable prediction of the project-specific health impacts of the emission changes associated with the replacement bridge corridor alternatives. Because of these limitations, the following discussion is included in accordance with President's CEQ regulations (Title 40 CFR Section 1502.22[b]) regarding incomplete or unavailable information.

4.9.5.2 Information that is Unavailable or Incomplete

Evaluating the environmental and health impacts from MSATs on a proposed highway project would involve several key elements, including emissions modeling, dispersion modeling in order to estimate ambient concentrations resulting from the estimated emissions, exposure modeling in order to estimate human exposure to the estimated concentrations, and then final determination of health impacts based on the estimated exposure. Each of these steps is encumbered by technical shortcomings or uncertain science that prevents a more complete determination of the MSAT health impacts of this project:

Table 4-30. US Annual Vehicle-Miles Traveled (VMT) vs. Mobile Source Air Toxics Emissions, 2000-2020

Notes: For on-road mobile sources. Emissions factors were generated using MOBILE6.2. MTBE proportion of market for oxygenates is held constant, at 50 percent. Gasoline RVP and oxygenate content are held constant. VMT: Highway Statistics 2000, Table VM-2 for 2000, analysis assumes annual growth rate of 2.5%. "DPM + DEOG" is based on MOBILE6.2-generated factors for elemental carbon, organic carbon and SO4 from diesel-powered vehicles, with the particle size cutoff set at 10.0 microns.

- Emissions. The USEPA tools to estimate MSAT emissions from motor vehicles are not sensitive to key variables determining emissions of MSATs in the context of highway projects. While MOBILE 6.2 (i.e., USEPA's updated version of their mobile source emission factor model that also includes particulate matter [PM] and MSATs) is used to predict emissions at a regional level, it has limited applicability at the project level. MOBILE 6.2 is a trip-based model. Projected emission factors are based on a typical trip of 7.5 miles (12.1 kilometers), and on average speeds for this typical trip. This means that MOBILE 6.2 does not have the ability to predict emission factors for a specific vehicle operating condition at a specific location at a specific time. Because of this limitation, MOBILE 6.2 can only approximate the operating speeds and levels of congestion likely to be present on larger projects, and cannot adequately capture emissions effects of smaller projects. For PM, the model results are not sensitive to average trip speed, although the other MSAT emission rates do change with changes in trip speed. Also, the emissions rates used in MOBILE 6.2 for both PM and MSATs are based on a limited number of tests of mostly older-technology vehicles. Lastly, in its discussions of PM under the conformity rule, USEPA has identified problems with MOBILE 6.2 as an obstacle to quantitative analysis.

  These deficiencies compromise the capability of MOBILE 6.2 to estimate MSAT emissions. MOBILE 6.2 is an adequate tool for projecting emissions trends and for performing relative analyses between alternatives for very large projects, but it is not sensitive enough to capture

the effects of travel changes tied to smaller projects or to predict emissions near specific roadside locations.

- Dispersion. The tools to predict how MSATs disperse also are limited. The USEPA's current regulatory models, CALINE3 and CAL3QHC, were developed and validated more than a decade ago for the purpose of predicting episodic concentrations of carbon monoxide to determine compliance with the NAAQS. The performance of dispersion models is more accurate for predicting maximum concentrations that can occur at some time at some location within a geographic area. This limitation makes it difficult to predict accurate exposure patterns at specific times at specific highway project locations across an urban area to assess potential health risk. The National Cooperative Highway Research Program (NCHRP) is conducting research on best practices in applying models and other technical methods in the analysis of MSATs. This work also will focus on identifying appropriate methods of documenting and communicating MSAT impacts in the NEPA process and to the public. Along with these general limitations of dispersion models, FHWA also is faced with a lack of monitoring data in most areas for use in establishing project-specific MSAT background concentrations.

- Exposure Levels and Health Effects. Finally, even if emission levels and concentrations of MSATs could be accurately predicted, shortcomings in current techniques for exposure assessment and risk analysis preclude reaching meaningful conclusions about project-specific health impacts. Exposure assessments are difficult because it is difficult to accurately calculate annual concentrations of MSATs near roadways, and to determine the portion of a year that people are actually exposed to those concentrations at a specific location. These difficulties are magnified for 70-year cancer assessments, particularly because unsupportable assumptions would have to be made regarding changes in travel patterns and vehicle technology (which affects emissions rates) over a 70-year period. There also are considerable uncertainties associated with the existing estimates of toxicity of the various MSATs because of factors such as low-dose extrapolation and translation of occupational exposure data to the general population. Because of these shortcomings, any calculated difference in health impacts between alternatives is likely to be much smaller than the uncertainties associated with calculating the impacts. Consequently, the results of such assessments would not be useful to decision makers, who would need to weigh this information against other project impacts that are better suited for quantitative analysis.

4.9.5.3 Summary of Existing Credible Scientific Evidence Relevant to Evaluating the Impacts of MSATs

Research into the health impacts of MSATs is ongoing. For different emission types, there are a variety of studies that show either that some are statistically associated with adverse health outcomes through epidemiological studies (frequently based on emissions levels found in occupational settings) or that animals demonstrate adverse health outcomes when exposed to large doses.

Exposure to toxics has been a focus of several USEPA efforts. Most notably, the agency conducted the National Air Toxics Assessment (NATA) in 1996 to evaluate modeled estimates of human exposure applicable to the county level. While not intended for use as a measure of or benchmark for local exposure, the modeled estimates in the NATA database best illustrate the levels of various toxics when aggregated to a national or State level.

The USEPA is in the process of assessing the risks of various kinds of exposures to these pollutants. The USEPA's Integrated Risk Information System (IRIS) is a database of human health effects that may result from exposure to various substances found in the environment (USEPA IRIS web site, 2006). The following toxicity information for the six prioritized MSATs was taken from the IRIS database "Weight of Evidence Characterization" summaries. This information is taken verbatim from USEPA's IRIS database and represents the USEPA's most current evaluations of the potential hazards and toxicology of these chemicals or mixtures:

- Benzene is characterized as a known human carcinogen;

- The potential carcinogenicity of acrolein cannot be determined because the existing data are inadequate for an assessment of human carcinogenic potential for either the oral or inhalation route of exposure;

- Formaldehyde is a probable human carcinogen, based on limited evidence in humans, and sufficient evidence in animals;

- 1,3-butadiene is characterized as carcinogenic to humans by inhalation;

- Acetaldehyde is a probable human carcinogen based on increased incidence of nasal tumors in male and female rats and laryngeal tumors in male and female hamsters after inhalation exposure;

- Diesel exhaust (DE) is likely to be carcinogenic to humans by inhalation from environmental exposures. DE as reviewed in this document is the combination of diesel PM and diesel exhaust organic gases; and

- DE also represents chronic respiratory effects, possibly the primary noncancer hazard from MSATs. Prolonged exposures may impair pulmonary function and could produce symptoms, such as cough, phlegm, and chronic bronchitis. Exposure relationships have not been developed from these studies.

Other studies address MSAT health impacts in proximity to roadways. The Health Effects Institute, a non-profit organization funded by USEPA, FHWA, and industry, has undertaken a major series of studies to research near-roadway MSAT hot spots, the health implications of the entire mix of mobile source pollutants, and other topics. The final summary of the series is not expected for several years.

Some recent studies have reported that proximity to roadways is related to adverse health outcomes, particularly respiratory problems. These studies are: *South Coast Air Quality Management District, Multiple Air Toxic Exposure Study-II* (2000); *Highway Health Hazards* by The Sierra Club (2004) summarizing 24 studies on the relationship between health and air quality; and NEPA's *Uncertainty in the Federal Legal Scheme Controlling Air Pollution from Motor Vehicles* by the Environmental Law Institute, 35 Environmental Law Regulation (ELR) 10273 (2005) with health studies cited therein. Much of this research is not specific to MSATs, instead surveying the full spectrum of both criteria and other pollutants. The FHWA cannot evaluate the validity of these studies, but more importantly, they do not provide information that would be useful to alleviate the uncertainties listed above and enable a more comprehensive evaluation of the health impacts specific to this project.

4.9.5.4 Relevance of Unavailable or Incomplete Information to Evaluating Reasonably Foreseeable Significant Adverse Impacts on the Environment, and Evaluation of Impacts Based Upon Theoretical Approaches or Research Methods Generally Accepted in the Scientific Community

Because of the uncertainties outlined above, a quantitative assessment of the effects of air toxic emissions impacts on human health cannot be made at the project level. While available tools do allow reasonable predictions of relative emissions changes between alternatives for larger projects, the amount of MSAT emissions from each of the replacement bridge corridor alternatives and MSAT concentrations or exposures created by each of the replacement bridge corridor alternatives cannot be predicted with enough accuracy to be useful in estimating health impacts. (As noted above, the current emissions model is not capable of serving as a meaningful emissions analysis tool for smaller projects.) Therefore, the relevance of the unavailable or incomplete information is that it is not possible to make a determination of whether any of the replacement bridge corridor alternatives would have "significant adverse impacts on the human environment."

In this FEIS, FHWA has provided a quantitative analysis of MSAT emissions relative to the replacement bridge corridor alternatives, (or a qualitative assessment, as applicable) and has acknowledged that the project may result in increased exposure to MSAT emissions in certain locations, although the concentrations and duration of exposures are uncertain, and because of this uncertainty, the health effects from these emissions cannot be estimated.

As discussed above, technical shortcomings of emissions and dispersion models and uncertain science with respect to health effects prevent meaningful or reliable estimates of MSAT emissions and effects of this project. However, even though reliable methods do not exist to accurately estimate the health impacts of MSATs at the project level, it is possible to qualitatively assess the levels of future MSAT emissions under the project. Although a qualitative analysis cannot identify and measure health impacts from MSATs, it can give a basis for identifying and comparing the potential differences among MSAT emissions, if any, from the replacement bridge corridor alternatives. The qualitative assessment presented below is derived in part from a study conducted by the FHWA entitled "*A Methodology for Evaluating Mobile Source Air Toxic Emissions among Transportation Project Alternatives"* (FHWA Environment web site, 2006).

For each replacement bridge corridor alternative in the FEIS, the amount of MSATs emitted would be proportional to the vehicle-miles traveled, or VMT, assuming other variables such as fleet mix are the same for each alternative. The VMT for each replacement bridge corridor alternative would vary by its length in comparison to that of the existing road configuration. The replacement bridge corridors alternatives would all have two through lanes, as such the capacity of NC 12 and the forecast traffic volumes are not expected to be affected by their implementation. The lengths of the various replacement bridge corridor alternatives measured from a common starting point in Rodanthe and ending point on Bodie Island would be:

- Pamlico Sound Bridge Corridor—18.7 miles (30.1 kilometers);
- Parallel Bridge Corridor with Road North/Bridge South—16.2 miles (26.1 kilometers);
- Parallel Bridge Corridor with Nourishment, Phased Approach (including the Preferred Alternative), and All Bridge—16.1 miles (25.9 kilometers); and
- Existing Road Configuration—16.0 miles (25.7 kilometers).

The VMT and potential MSAT emissions for most of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be nearly identical to the existing road configuration, because their lengths are nearly identical and no change in forecast traffic volumes is expected. The VMT and potential MSAT emissions would be 17 percent higher with the Pamlico Sound Bridge Corridor compared to the existing road configuration because of its longer length.

Regardless of the replacement bridge corridor alternative chosen, emissions will likely be lower in the design year than present levels, as a result of USEPA's national control programs that are projected to reduce MSAT emissions by 57 to 87 percent between 2000 and 2020. Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control measures. However, the magnitude of the USEPA-projected reductions is so great (even after accounting for VMT growth with the Pamlico Sound Bridge Corridor) that MSAT emissions in the study area are likely to be lower in the future in nearly all cases.

The relocated sections of NC 12 contemplated as part of the replacement bridge corridor alternatives would have the effect of moving some traffic closer to nearby homes, businesses, and recreational trails; therefore, under each alternative (except the Parallel Bridge Corridor with Nourishment Alternative) there may be localized areas where ambient concentrations of MSATs could be higher than the existing road configuration. The localized increases in MSAT concentrations would likely be most pronounced along new roadway sections in Rodanthe. However, as discussed above, the magnitude and the duration of these potential increases compared to the existing road configuration cannot be accurately quantified because of the inherent deficiencies of current models. In sum, when NC 12 is relocated and, as a result, moves closer to receptors, the localized level of MSAT emissions for the replacement bridge corridor alternatives could be higher relative to the existing road configuration, but this could be offset by MSATs being lower in other locations when traffic shifts away from them. However, on a regional basis, USEPA's vehicle and fuel regulations, coupled with fleet turnover, will over time cause substantial reductions that, in almost all cases, will cause region-wide MSAT levels to be substantially lower than today.

4.10 Noise

The noise level and abatement analysis for the replacement bridge corridor alternatives were conducted at 36 receptors on Bodie and Hatteras Islands. The results of this analysis indicate that FHWA's NAC would be approached or exceeded at three or four residences depending on the Pamlico Sound Bridge Corridor Rodanthe terminus option implemented. The NAC would be approached or exceeded at four residences with the Parallel Bridge Corridor with Nourishment Alternative and the Phased Approach/Rodanthe Nourishment Alternative. The NAC would be approached or exceeded at two residences with the other Parallel Bridge Corridor alternatives. A substantial increase in noise levels would occur at two residences with either Pamlico Sound Bridge Corridor terminus option. No reasonable or feasible opportunities exist to reduce noise levels at any of these residences.

The No-Action Alternative assumes that Bonner Bridge is demolished at the end of its service life and not replaced. This likely would result in a dramatic but unknown decrease in traffic on NC 12, since limited ferry capacity would discourage visitors to Hatteras Island and future growth in the permanent population. Thus, No-Action Alternative noise levels could not be modeled for comparison with the replacement bridge corridor alternatives, as is customary for this type of analysis. Noise levels were, however, modeled assuming 2025 traffic on NC 12 if Bonner Bridge were to remain in place.

4.10.1 Traffic Noise Model

Traffic noise predictions were performed using the FHWA's Traffic Noise Model (TNM), Version 2.5 (2004). The TNM takes into account factors such as ground absorption, roadway geometry, receptor distance, operating speed, and traffic volumes.

Noise from existing traffic, traffic in 2025 (assuming Bonner Bridge was to remain in place), and traffic in 2025 with the replacement bridge corridor alternatives were modeled. Three vehicle classifications were assumed: cars (all vehicles with two axles and four tires), medium trucks (all cargo vehicles with two axles and six tires), and heavy trucks (all cargo vehicles with three or more axles). Peak-hour traffic noise was determined. In order to depict worst-case conditions peak season, Saturday traffic volumes were used.

Assessment of traffic noise impact requires the following three comparisons:

- The change in noise levels from existing conditions to future conditions with the proposed project and whether that difference is substantial;
- The difference in future noise levels with and without the project; and
- Whether noise levels with the proposed project would exceed the FHWA's NAC.

The FHWA's NAC and the definition of what constitutes a substantial increase were presented in Section 3.10.2.

4.10.2 Predicted Noise Levels

Thirty-six noise-sensitive receivers were modeled for the replacement bridge corridor alternatives. Their locations are shown in Figure 4-2. The predicted noise levels are presented in Table 4-31.

4.10.3 Noise Analysis

Receptors at which the FHWA's NAC would be exceeded are:

- Parallel Bridge Corridor
  - Nourishment: 14, 15, 18, 20
  - Road North/Bridge South: 14, 15
  - All Bridge: 14, 15
  - Phased Approach/Rodanthe Nourishment: 14, 15, 18, 20
  - Phased Approach/Rodanthe Bridge (Preferred): 14, 18
- Pamlico Sound Bridge Corridor
  - Curved Rodanthe Terminus: 14, 15, 18
  - Intersection Rodanthe Terminus 14, 15, 18, 20

[1]Receptor locations are shown in Figure 4-2.
[2]Levels shown are 1 dBA less than the criteria presented in Table 3-26, reflecting the policy to consider noise abatement measures when peak hour noise levels approach the criteria levels.
*Preferred Alternative

These receptors would also approach or exceed the NAC assuming Bonner Bridge remains in place. The increased future noise levels are associated more with the forecast growth in traffic than the implementation of the proposed project in that where the NAC is exceeded the associated noise level is in every case identical to the level that would occur if Bonner Bridge remained in place.

A substantial increase in noise levels would occur at two residences (25 and 26) with the Curved Rodanthe Terminus option and at two residences (23 and 26) with the Intersection Rodanthe Terminus of the Pamlico Sound Bridge Corridor. None of these receptors currently experience traffic noise from existing NC 12. Substantial increases are defined as 15 dBA or more where the existing L_{eq} is 50 dBA or less, or 10 dBA or more where the existing L_{eq} is greater than 50 dBA.

The effect of traffic noise resulting from the Parallel Bridge Corridor was analyzed for the Refuge. The Refuge was assessed in accordance with FHWA's NAC applicable to Activity Category "B" which is 67 dBA (or 66 dBA approaching). Activity Category "B" includes parks, recreation areas, picnic areas, residences, hospitals, and schools. The results of the analysis indicate that the 66 dBA contour in 2025 would be approximately 117 feet (35.7 meters) and the existing 66 dBA contour is 96 feet (29.3 meters) from the centerline of the Parallel Bridge Corridor alternatives exclusive of dunes along the shoreline, which can serve to reduce noise levels on the beach. The difference reflects traffic growth from 2002 to 2025. With the Pamlico Sound Bridge Corridor, traffic would drop within the Refuge in that through trips (trips without a destination within the Refuge) in the Refuge would be eliminated. See Table 3-26 for more information on noise abatement criteria.

4.10.4 Project Noise Abatement

The feasibility and reasonableness of noise abatement measures were evaluated for the affected sensitive sites (14, 15, 18, 20, 23, 25, and 26). Feasibility of an abatement measure deals primarily with design and engineering considerations. Reasonableness is a more subjective measure and demonstrates that good judgment and common sense are used in making a decision with respect to the abatement measure.

As outlined in 23 CFR 772, abatement can include the following mitigation measures: noise barriers, transportation system management, alignment modifications, and land use control. When noise abatement measures are being considered, every effort should be made to obtain substantial noise reduction at the affected receivers. The design goal of an abatement measure is a reduction of 8 dBA or more. If a minimum reduction of 5 dBA cannot be achieved, an abatement measure is not considered feasible.

The sections that follow discuss the noise abatement measures that were investigated to reduce noise levels at the seven receptors.

4.10.4.1 Noise Barriers

Noise barriers reduce noise levels by blocking the sound path between the roadway and noise sensitive sites. To be effective in reducing traffic noise impacts, a noise barrier must have certain characteristics:

- Long (the barrier should extend four times as far in each direction as the distance from the receiver to the barrier);

- Continuous (with no gaps or discontinuities in the design whether they be for pedestrian access, cross-street penetration, or access to the roadway for maintenance purposes); and

- Sufficiently high to provide the necessary reduction in noise levels at an affected site.

In order for a barrier to be considered feasible and reasonable, it must meet the following minimum criteria:

- Provide a minimum insertion loss (noise reduction) of 5 dBA to all of the affected sites, with a design goal of 8 dBA for the receivers immediately behind the barrier.

- The cost to construct the barrier should not exceed $35,000 per benefited receptor plus an incremental increase of $500 per dBA average increase in the predicted exterior noise levels of the affected receptors of the area. For purposes of this determination, benefited receptors are those that would experience a reduction of 5 dBA or more in the level of traffic noise as a result of the noise barrier.

Barrier analyses were conducted at receptors where predicted noise levels would approach or exceed the NAC. The TNM computer program was utilized to evaluate the cost-effectiveness and acoustic-effectiveness of noise barriers. Noise barriers of varying heights and lengths were modeled at each location considered. The results of the noise barrier analyses were compared to the minimum criteria.

After review of the noise level results and geometry of the project, it is not considered reasonable or feasible to construct noise barriers at any affected sensitive receptor for the following reasons:

- The noise-sensitive sites in Rodanthe are low-density residences. The four sites where NAC levels would be approached or exceeded are separated from each other by other development, and one is on the opposite site of NC 12 from the other three. The three homes where a substantial increase would occur with the Curved Rodanthe Terminus and the Intersection Rodanthe Terminus are isolated receptors. Noise barriers would not be cost-effective (less than $35,000 per benefited receptor plus an incremental increase of $500 per dBA average increase) in such settings. The NCDOT does not provide noise abatement for isolated receptors.

- For the noise-sensitive areas along NC 12, acoustically effective noise barriers would block or limit the access of residents to NC 12 by blocking driveways and side streets.

For the four homes planned or under construction near Pamlico Sound, acoustically effective noise barriers likely would block or limit the access of residents with the Curved Rodanthe Terminus. A barrier likely would be effective at the two homes remaining near the Sound with the Intersection Rodanthe Terminus.

4.10.4.2 Transportation System Management Measures

Transportation system management measures that limit motor vehicle speeds and reduce traffic volumes can be effective noise mitigation measures. However, these measures also negate a project's ability to accommodate forecasted traffic volumes.

4.10.4.3 Alignment Modifications

Alignment modifications generally involve orienting and/or siting the proposed project at sufficient distances from noise-sensitive areas to minimize noise impacts. As discussed in Sections 2.2 to 2.6, the study team evaluated numerous locations for the proposed project. The locations of the alternatives under consideration offer the best set of alternatives that balance engineering criteria, limitations imposed by terrain and the various community, cultural resource and natural resource impacts.

4.10.4.4 Land Use Controls

Another noise abatement measure is the use of land use controls to minimize impacts to future development. Dare County, the NPS, and the USFWS could consider anticipated noise level changes along the Phased Approach/Rodanthe Bridge Alternative (Preferred) so that new homes and other sensitive uses are set back from the Preferred Alternative sufficiently to avoid noise impact. In Rodanthe, a setback distance of 100 feet (30 meters) from the center of the nearest travel lane of the replacement bridge corridor alternatives to the 66 dBA noise level was calculated. Traffic noise levels should not exceed 66 dBA at new homes set back at least 100 feet (30 meters) from the road.

The 66 dBA contour in 2025 within the Refuge and Seashore would be approximately 117 feet (35.7 meters) from the centerline of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) exclusive of dunes along the shoreline.

4.11 Energy

Energy use by the replacement bridge corridor alternatives and the No-Action Alternative can be characterized as follows:

- Construction. Energy would be used for the manufacturing of bridge components and by the heavy equipment needed to build the replacement bridge corridor alternatives. For the No-Action Alternative, energy would be used to build the facilities and boats for the small ferry service that would be a part of that alternative.

- Maintenance. All of the bridges associated with the replacement bridge corridor alternatives would require routine maintenance for 40 years, after which a major rehabilitation program would be expected. The road components would require routine maintenance annually and major maintenance every 12 years. Dunes would lose half their volume and would be restored every 12 years. Nourishment would be repeated every four years. The No-Action Alternative would necessitate use of energy to repair Bonner Bridge until it is demolished because of continuing spalling and scour problems. After storms, dune and road restoration along NC 12 would be expected. The No-Action Alternative's small-scale ferry service would require maintenance of ferry facilities and regular dredging of a ferry channel across Oregon Inlet.

- Demolition and Removal. Both of the replacement bridge corridor alternatives would require demolition and removal of Bonner Bridge (which would occur under a separate contract than for the construction of the proposed project with the Pamlico Sound Bridge Corridor). The energy use by equipment would be the same.

- Motor Vehicle or Ferry Use. The replacement bridge corridor alternatives would allow traffic volumes across Oregon Inlet and down Hatteras Island to continue to grow. Fuel usage would increase. Traffic volumes and related energy use, however, would not be greater than would be expected if Bonner Bridge could remain in service. The No-Action Alternative would reduce accessibility greatly to Hatteras Island and, therefore, reduce the amount of energy being spent in travel to this destination. The overall difference in energy from the operational (traffic) perspective of the No-Action Alternative and the replacement bridge corridor alternatives would be minimal, however, since the tourist traffic now going to Hatteras Island likely would go to another tourist location. There is no reason to believe that the reduction of access to Hatteras Island would cause a substantial number of motorists to eliminate their plans to travel. They likely would travel somewhere, just not necessarily to Hatteras Island or Dare County. The No-Action Alternative also would require additional energy use by ferries.

- Motor Vehicle or Ferry Manufacture and Maintenance. Energy also would be used to manufacture and maintain the motor vehicles that would use the replacement bridge corridor alternatives and travel on Hatteras Island. This use of energy would not be substantially different with the No-Action Alternative for the same reasons motor vehicle fuel usage would not differ substantially between the replacement bridge corridor alternatives and the No-Action Alternative. Energy also would be required to manufacture and maintain the No-Action Alternative ferries.

Differences in energy use related to the construction and maintenance of the replacement bridge corridor alternatives are reflected in differences in their cost. The higher the cost, the more energy is expended. The cost information in Tables 2-9 and 2-10 indicates that the relative energy use of the replacement bridge corridor alternatives from greatest to least use would be:

1. Either Pamlico Sound Bridge Corridor (2.2 to 2.4 times the energy use of the least use alternative);

2. Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative (1.9 to 2.0 times the energy use of the least use alternative);

3. Parallel Bridge Corridor with All Bridge (1.8 to 2.0 times the energy use of the least use alternative);

4. Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) (1.8 to 1.9 times the energy use of the least use alternative);

5. Parallel Bridge Corridor with Nourishment (1.1 to 1.3 times the energy use of the least use alternative); and

6. Parallel Bridge Corridor with Road North/Bridge South (the least energy use alternative).

Without a detailed analysis of energy usage, a numeric difference in energy use between the replacement bridge corridor alternatives and the No-Action Alternative cannot be presented. Such an analysis is not considered necessary to making a sound decision regarding whether to implement one of the replacement bridge corridor alternatives and how to mitigate its impacts. The following can be observed, however, from the discussion above:

- Undoubtedly, the energy used in constructing one of the replacement bridge corridor alternatives would be greater than that required to build the small-scale ferry service associated with the No-Action Alternative. This benefit, however, would be offset, at least in part, by the higher maintenance and operation energy use of the No-Action Alternative.

- A substantial difference in motor vehicle energy use would not be expected between the replacement bridge corridor alternatives and the No-Action Alternative. The No-Action Alternative, however, would involve the use of energy to manufacture and operate ferries.

4.12 Indirect and Cumulative Impacts

The President's CEQ regulations for environmental impact documentation (CFR, Title 40, Section 1508(1)) includes definitions for indirect and cumulative impacts (ICI). These definitions are:

> Indirect effects are those "which are caused by the [proposed] action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include induced growth and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems." (40 CFR 1508.8(b))
>
> "Cumulative impact is the impact on the environment which results from the incremental impact of the [proposed] action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." (40 CFR 1508.7)

This assessment of indirect and cumulative impacts is based on the guidance contained in the NCDOT's and the NCDENR's *Guidance for Assessing Indirect and Cumulative Impacts of Transportation Projects in North Carolina* (The Louis Berger Group, 2001). Impacts directly associated with the construction and operation of each of the alternatives, whether they occur within the project right-of-way or easement (such as biotic community use) or outside the project right-of-way or easement (such as noise), are assessed in the other topical sections of this FEIS.

Because the proposed project would consist of the replacement of an existing bridge, as well as an existing road in the case of the Parallel Bridge Corridor, indirect and cumulative impacts would be minimal. The replacement bridge corridor alternatives would not alter area development trends. The Pamlico Sound Bridge Corridor would complement the goals of the Outer Banks Task Force, including its efforts to develop both short-term and long-term plans for maintaining a transportation system on the Outer Banks in light of recent trends of shoreline erosion and highway overwash on NC 12. The Parallel Bridge Corridor would address long-term NC 12 needs, but would be less supportive of the natural resource protection goals of the Task Force than the Pamlico Sound Bridge Corridor.

The Pamlico Sound Bridge Corridor, given that it would bypass the Refuge, could affect future decision-making related to:

- Activities associated with NC 12 maintenance in the Refuge;

- Access within the Seashore north of Rodanthe and the Refuge;

- Oregon Inlet dredging and associated impacts to the bottom of Pamlico Sound;

- The preservation and re-use of the (former) US Coast Guard Station at the north end of Hatteras Island; and

- The disposition of the terminal groin at the north end of Hatteras Island.

The specific direction these future decisions might take is not foreseeable. In all cases, however, planning and environmental studies would be conducted before any final decisions are made. The NCDOT will participate in those studies.

The Parallel Bridge Corridor, which leaves NC 12 within the Refuge, also would influence future Outer Banks Task Force activities associated with NC 12 maintenance in the Refuge and access within the Seashore north of Rodanthe and the Refuge. The Parallel Bridge Corridor would influence future dredging decisions from two perspectives:

1. The longer navigation zone of the Oregon Inlet bridge would allow the dredged channel to move with the natural gorge.

2. Some dredging spoils could be used as a part of the Parallel Bridge Corridor with Nourishment Alternative.

The terminal groin would be retained with the Parallel Bridge Corridor, although an opportunity could exist for the groin's removal with the All Bridge Alternative and upon completion of Phase II of the Phased Approach alternatives (including the Preferred Alternative). These alternatives would bridge the area affected as Oregon Inlet resumes its movement south after the groin is removed. The retention of the groin would allow the (former) US Coast Guard Station to remain in its current location with access to NC 12, if desired by its owners.

4.12.1 Study Area

The boundaries of the indirect and cumulative impacts study area encompass:

- The area where the implementation of the project could potentially influence decision-making associated with other actions;

- The area of influence of the proposed project on Oregon Inlet navigation;

- The boundaries of the Refuge, the Seashore on Hatteras Island, and the communities on Hatteras Island;

- The (former) US Coast Guard Station at the north end of Hatteras Island;

- The area of potential NC 12 long-term relocation options on Hatteras Island;

- The Bonner Bridge replacement study's project area as defined in Section 1.3.1; and

- The North Carolina northern Outer Banks.

These parameters encompass the potential area of influence of the proposed project in terms of the potential to affect growth trends, interact with other proposed actions, affect other activities in the region, and the affect of habitat loss, degradation, and fragmentation on the diversity, biological integrity, and ecological integrity of the northern Outer Banks. These parameters define an area that includes:

- All of Hatteras Island;
- The southern end of Bodie Island in the vicinity of the northern terminus of Bonner Bridge and the proposed project;
- Oregon Inlet;
- Pamlico Sound as far west of Hatteras Island as the path of the Pamlico Sound Bridge Corridor; and
- The North Carolina northern Outer Banks.

The features of this study area are shown on Figure 1-1 and Figure 3-3 (the (former) US Coast Guard Station). The Pamlico Sound Bridge Corridor is shown on Figure 2-11. The three alternatives associated with the Parallel Bridge Corridor are shown on Figure 2-18 to Figure 2-20.

4.12.2 Directions and Goals

The ICI study area is within the jurisdiction of Dare County's land use plan, the 1974 CAMA, and the NPS's plans for the Seashore. These plans are described in detail in Section 3.1.3 and are summarized in the sections that follow.

4.12.2.1 Dare County Land Use Plan

The *Dare County Land Use Plan, 2003 Update* provides a set of guidelines to manage growth and development in unincorporated Dare County over the next five years. The land use plan recognizes the priority of the transportation needs in Dare County and contains specific policies for the protection of NC 12 and coordination with the NCDOT for a replacement of Bonner Bridge. One goal of the land use plan is to maintain the "coastal village" atmosphere of the County. It supports the re-use of historic residential structures for business or commercial purposes. One of the major changes in the 2003 plan from the 1994 plan is the relaxation of wetland mitigation. Because of the strict language in the 1994 plan, some public projects in Dare County experienced problems. The policy in the 2003 plan is intended to provide more flexibility so as not to preclude projects that would benefit Dare County and its citizens. The 2003 plan also supports beach nourishment to maintain the shoreline.

4.12.2.2 Coastal Area Management Act

The 1974 CAMA calls for the identification of certain environmentally fragile and important land and water areas that are judged to be of greater-than-local significance. The NCCRC, in cooperation with local governments in a 20-county coastal area, has developed a program of permit review and coordination within these AEC. Dare County has substantial amounts of environmentally fragile areas and much of these lands have been designated as AECs. The Seashore and the Refuge are protected by an AEC designation. Thus, the entire ICI study area is protected, except for the communities scattered along Hatteras Island (see Figure 1-1).

The NCDENR's Division of Coastal Management (DCM) uses the Dare County land use plan when making CAMA permit decisions. Proposed development must be consistent with the local land use plan, or the DCM will not permit a planned development to be implemented.

4.12.2.3 National Park Service Plans

The NPS's *Management Policies* (NPS, 2001) is the basic Service-wide policy document of the NPS. The *General Management Plan and Amended Environmental Assessment for Cape Hatteras National Seashore* (NPS, 1984) and the *Draft Revised Statement for Management* (NPS, 1991) serve as the NPS plans for the Seashore. These documents provide for the preservation of the cultural resources and the flora, fauna, and natural physiographic conditions, while allowing appropriate recreational use and public access to the oceanside and soundside shores. Impairment of park resources and values by projects such as the proposed project is prohibited by law. It is the desire of the NPS to no longer attempt to stabilize the Outer Banks artificially, but rather to let natural processes take their course. No new Seashore facilities are planned in the ICI study area. The plans for the Seashore focus on restoration and maintenance of existing facilities.

4.12.2.4 Pea Island National Wildlife Refuge Plan

The USFWS prepared a *Comprehensive Conservation Plan* (USFWS, 2006) to guide the management of the Refuge. The plan, which was published in September 2006, outlines programs and corresponding resource needs for the proceeding 15 years, as mandated by the National Wildlife Refuge System Improvement Act of 1997. The purpose of the plan is to identify the role that the Refuge will play in support of the mission of the National Wildlife Refuge System and to provide long-term guidance to the Refuge's management programs and activities.

4.12.3 Notable Features

Notable features in the ICI study area are defined in Chapter 3 and Chapter 5. They are:

- Cape Hatteras National Seashore, as described in Section 3.5 and Section 5.1.1;
- The communities scattered along Hatteras Island, as described in Sections 3.1.2, 3.1.6, 3.1.7, and 3.1.8;
- Oregon Inlet, including its natural features and its use for navigation, as described in Sections 3.1.9, 3.6, 3.7.2, 3.7.3.1, and 3.7.6.1;
- Several historic resources, as described in Sections 3.4.1, 5.1.3, and 5.1.4;
- Pea Island National Wildlife Refuge, including its recreational and natural features as described in Sections 3.4.1.1, 3.5, 3.7.5, 3.7.6.5, and 5.1.2; and
- Pamlico Sound, as described in Sections 3.7.2, 3.7.3.1, and 3.7.6.1.

4.12.4 Other Potential Impact Causing Activities

Other potential impact causing activities in the ICI study area are:

- Future development and redevelopment on privately held lands on Hatteras Island;
- Actions associated with the goals of the Outer Banks Task Force;
- Potential changes in access within the Refuge and the Seashore north of Rodanthe that could result from moving the southern terminus of the bridge over Oregon Inlet from the north end of Hatteras Island (with Bonner Bridge) to Rodanthe (with the Pamlico Sound Bridge Corridor);
- Dredging for navigation of Oregon Inlet by the USACE;
- Preservation and re-use of the (former) US Coast Guard Station at the north end of Hatteras Island;
- Future disposition of the terminal groin at the north end of Hatteras Island;
- Relocation of utilities in response to shoreline erosion; and
- Past and future development and redevelopment on privately held lands on the Outer Banks and the disturbance of beaches on public and privately held lands on the Outer Banks.

4.12.4.1 Future Development and Redevelopment

The *Dare County Land Use Plan* indicates that new development, particularly national retail franchises and "chains," should maintain the look and feel of the surrounding community. The plan anticipates that future development will shift from new development toward redevelopment of land. It supports the re-use of historic residential structures for business or commercial purposes. The plan also predicts that the limited number of commercial enterprises in the County will move toward serving the needs of year-round residents rather than seasonal visitors.

4.12.4.2 Relocation or Protection of Portions of NC 12

The Outer Banks Task Force is a partnership that includes representatives from the NCDOT, the FHWA, the USACE, the NPS, the USFWS, the National Marine Fisheries Service, the NCDENR, and other state and federal environmental resource and regulatory agencies. Its overall purpose under its now expired Memorandum of Agreement was to develop both short-term and long-term protection and maintenance plans for the transportation system on the Outer Banks. Its goals include:

- Preserving the natural barrier island system;
- Minimizing impacts to Hatteras and Ocracoke islands; and
- Maintaining access to and on the islands so that the transportation system is safe, efficient, and has minimal impact on the environment.

One objective of the work of the Outer Banks Task Force was to develop both short-term and long-term plans for maintaining a transportation system on the Outer Banks in light of recent trends of shoreline erosion and highway overwash along NC 12. The five replacement bridge corridor alternatives all would provide a long-term solution to highway overwash along NC 12.

4.12.4.3 Changes in Access within Pea Island National Wildlife Refuge/Cape Hatteras National Seashore

A bridge in the Pamlico Sound Bridge Corridor would provide transportation access between Bodie Island and Rodanthe instead of the existing road that passes through the Seashore north of Rodanthe, as well as the Refuge. The Parallel Bridge Corridor would leave NC 12 at or near its current location. In 1973, the NPS—realizing the problems that a managed dune system caused—decided to no longer attempt to stabilize the Outer Banks artificially. Their current desire is to let natural processes take their course. In its 1991 *Draft Revised Statement for Management*, the Park Service affirmed a desire to manage the Seashore in ways "that support the natural processes of barrier island dynamics..." (NPS, 1991). This long-term desire has not changed despite recent threats to existing NC 12 within the Seashore. The USFWS, which is responsible for the Refuge, affirms this desire. Dune restoration and beach nourishment efforts by the NCDOT to protect NC 12 are an exception to that desire. Given the location of the Pamlico Sound Bridge Corridor and Seashore/Refuge policies, officials of the Refuge and Seashore planned to reassess their approach to access within the Seashore north of Rodanthe and the Refuge if that Corridor had been selected as the Preferred Alternative.

4.12.4.4 Dredging for Navigation of Oregon Inlet by the US Army Corps of Engineers

The USACE intends to continue dredging in the Oregon Inlet area to provide for navigation between Pamlico Sound and the Atlantic Ocean for commercial and recreational boats.

4.12.4.5 (Former) US Coast Guard Station Preservation

The North Carolina Aquarium Society, a division of NCDENR, manages the (former) US Coast Guard Station at the north end of Hatteras Island (see Figure 3-3). They intend to restore it and use it as a part of their educational programs. The SHPO does not object to this intent. Although no specific plans or funding for the restoration of the station are finalized, the Aquarium Society let a project for bidding in July 2008 to stabilize the structure, remove its modern dormitory, and restore the exterior. The objective of this contract would be to stabilize the structure until final decisions are made regarding the Bonner Bridge replacement project. Additional options discussed in the past for the future disposition of the station include leaving it at its present site or moving it to another location near the ocean.

4.12.4.6 Future Disposition of the Terminal Groin

The continued migration of Oregon Inlet threatened the southern terminus of Bonner Bridge and the north end of Hatteras Island in the late 1980s. Thus, the NCDOT built a terminal groin to protect the bridge. Construction of the terminal groin began in October 1989, and it was completed in March 1991. The groin was designed by the USACE Wilmington District. With the construction of the terminal groin, Hatteras Island migration to the south was halted. The NCDOT has no current plans to remove the terminal groin on Hatteras Island after Bonner Bridge is demolished. The terminal groin is not needed in order to build and maintain a bridge in the Pamlico Sound Bridge Corridor, and neither is its removal. The groin is necessary for construction and maintenance of a bridge in the Parallel Bridge Corridor. The performance of the

terminal groin would not be affected by the construction of a bridge within either replacement bridge corridor alternative.

If a bridge in the Pamlico Sound Bridge Corridor is built, the terminal groin could serve parties other than the NCDOT and other immediate needs besides protecting Bonner Bridge. It is conceivable, however, that circumstances could change at some time in the future such that it could prove prudent to remove the terminal groin. In addition, the permit from the Refuge that allowed the construction of the terminal groin states that the purpose of the terminal groin is to: "…protect the southern segment of the existing Herbert C. Bonner Bridge and its southern approach of North Carolina Highway 12." The permit also states that the NCDOT can use the lands and waters occupied by the terminal groin for as long as they "are used for the purpose granted." Whichever replacement bridge corridor alternative is selected as the preferred alternative, a new permit would need to be obtained from the USFWS in order for the groin to remain after Bonner Bridge is taken out of service and demolished. If USFWS officials ask the NCDOT to remove the groin following completion of the demolition and removal of Bonner Bridge, the NCDOT and representatives of the USFWS would assess the impacts of groin removal in a separate environmental study, as needed, prior to any final decision to remove the terminal groin.

4.12.4.7 Relocation of Utilities

As the shoreline erodes west on Hatteras Island with all alternatives under consideration except when nourishment is a component, telephone and electrical lines will have to be moved west. These lines roughly parallel NC 12, on poles and on Bonner Bridge. Like NC 12, these utility lines also are placed in jeopardy by shoreline erosion. Thus, it is reasonably foreseeable that these lines would need to be moved one or more times between now and the design year of this analysis, 2060. Costs for such relocations are included in the non-highway and potential non-highway costs discussed in Section 2.12.3. How such relocations might occur is not known.

4.12.4.8 Outer Banks Shoreline Development and Use

Prior to human disturbance, the project area most likely consisted of beach, wetlands, low dunes, and maritime shrub/forest communities. Much of the Outer Banks, outside of state and federal lands, has been developed for residential and commercial use. Although largely "undeveloped," most of the project area was occupied by natural vegetation communities that have been altered by past or current human-influenced disturbances. Disturbances in the project area include the construction of NC 12, construction and maintenance of primary dunes designed to prevent natural, landward migration of Hatteras Island, and construction of man-made impoundments on the Refuge. Except for activities associated with the maintenance of NC 12, the shoreline in the project area is generally not disturbed as most of it is on Hatteras Island within the Refuge. Table 4-32 gives linear measurements describing the nature of the project area as it compares to the Outer Banks as a whole. In general, federal and state lands are undeveloped and include natural beach, while private lands are developed, adjacent to development, or potentially developed in the future. Natural shoreline, and the coastal habitat created by natural shoreline movement, is essential for imperiled species such as the piping plover, seabeach amaranth, and sea turtles.

Table 4-32 indicates that approximately 76.8 miles of 126.7 miles (123.6 to 203.9 kilometers) or 61 percent of the length of the Outer Banks remains in state and federal ownership and as such is generally not developed. The project area includes 14.5 miles (23.3 kilometers) or 19 percent of that length. When one focuses on undisturbed shoreline, Table 4-32 indicates that of the Outer Banks shoreline, only 10 percent can be considered undisturbed or potentially undisturbed by development and beach driving. Almost all of that area (92 percent) is in the project area.

Table 4-32. Disturbance of the Outer Banks

	Land Ownership[1]			Total Miles
	Federal	State	Private	
Miles (kilometers) of the Outer Banks (measured along the shoreline)				
• In the Outer Banks	76.2 (122.6)	0.6 (1.0)	49.9 (80.3)	126.7 (203.9)
• In the Project Area	14.5 (23.3)	0.0 (0.0)	1.4 (2.3)	15.9 (25.6)
• Percent of the Outer Banks Shoreline Occupied by the Project Area	19%	0%	3%	13%
Miles (kilometers) of Drivable Beach[2]				
• In the Outer Banks	63.1 (101.6)	0.6 (1.0)	36.7 (59.1)	100.5 (161.7)
• In the Project Area	2.4 (3.9)	0.0 (0.0)	1.4 (2.3)	3.8 (6.1)
• Percent of Drivable Beach Miles Occupied by the Project Area	4%	0%	4%	4%
Miles (kilometers) of Undisturbed Shoreline (Non-Drivable Beach Without Adjoining or Potential Adjoining Development)				
• Total in the Outer Banks	13.1 (21.1)	0	0	13.1 (21.1)
• Total in the Project Areas	12.1 (19.5)	0	0	12.1 (19.5)
• Percent in the Project Areas	92%	0%	0%	92%
Percent Undisturbed Beach in the Entire Outer Banks	17%	0%	0$	10%

[1]Indicates ownership of the shoreline along particular segments of the Outer Banks. Federal and state land boundary shapefiles obtained from NC OneMap, 2007. The Outer Bank includes the North Carolina barrier islands from the Virginia line to Ocracoke, inclusive of Bodie, Hatteras, and Ocracoke islands.
[2]Areas where driving is allowed at some time during the year. Only Duck, Southern Shores, Kitty Hawk, the Refuge, and approximately 1 mile (1.6 kilometers) of Hatteras Point were considered off-limits to beach driving. There may be other small sections where driving is restricted.

4.12.5 Potential Indirect Impacts

Indirect effects include induced growth and other effects related to induced changes in the pattern of land use, population density, or growth rate. Construction of a project within the replacement bridge corridor alternatives would not induce changes in development trends because it:

- Does not have an economic development purpose other than to allow the economic benefits offered by the existing Bonner Bridge to continue. The need for a crossing of the Oregon Inlet will continue past the end of the service life of Bonner Bridge. Continued demand for convenient daily and emergency access across Oregon Inlet is expected to occur. The purpose of the proposed project is to replace an existing bridge before the end of its reasonable service life.

- Would be consistent with local area land use goals and directions as they are depicted in the *Dare County Land Use Plan* and, from the perspective of development trends on Hatteras Island, the requirements of the CAMA.

Does not serve a specific land development, would be unlikely to stimulate land development having complementary functions, and would be unlikely to influence substantial intraregional land development location decisions. The project would replace an existing two-lane bridge and road or bypass a portion of existing NC 12 with a new two-lane bridge. As such, it is a replacement in kind. Road capacity, accessibility, and travel time to the developed section of the Outer Banks would not change noticeably. Thus, the project would not be expected to result in changes in development rates or patterns on Hatteras Island, nor would it generate changed or increased development-related impacts. Its influence on land use decisions would be confined to the Rodanthe terminus (except the Nourishment Alternative, which does not relocate NC 12 in Rodanthe) where the presence of the bridge terminus and associated noise could influence decisions on how that land might develop in the future. Much of the land in the area of the terminus is presently used for an automobile junkyard, although a portion of that junkyard was cleared and some of the land developed between 2003 and 2004. Both commercial and residential development also exists in the area.

- Is not being introduced to an area with notable natural features that could be lost to development, as described in the previous bullet point and in Section 3.1.2.

Therefore, a project in either the Pamlico Sound Bridge Corridor or the Parallel Bridge Corridor would be unlikely to generate additional development in the ICI study area or development that is not consistent with local goals for developable areas. New or changed use of environmental resources that can be associated with changes in development trends would not occur.

4.12.6 Potential Cumulative Impacts

Cumulative impact is the impact on the environment which results from the incremental impact of a proposed action when added to other reasonably foreseeable future actions. The following sections describe the potential for cumulative impacts from the perspective of the replacement bridge corridor alternatives and their interaction with other proposed actions in the ICI study area.

4.12.6.1 Impacts Associated with Outer Banks Task Force Goals

The proposed bridge in the Pamlico Sound Bridge Corridor would complement the Outer Banks Task Force goals by bypassing three locations on NC 12 (hot spots) where shoreline erosion and ocean overwash of the highway during storms is a particular problem. The proposed bridge in the Pamlico Sound Bridge Corridor would meet all three goals of the Outer Banks Task Force (see Section 2.3) for the area it serves. It would provide safe transportation access to Hatteras Island that would allow for future natural movement of the island north of Rodanthe, while minimizing impacts to the island and preserving the natural barrier island system.

The Parallel Bridge Corridor would provide safe transportation access to Hatteras Island north of Rodanthe. However, the Parallel Bridge Corridor alternatives would affect the Refuge via nourishment and artificial dunes (Nourishment and Phased Approach/Rodanthe Nourishment alternatives), construction of an aerial structure (All Bridge Alternative and both Phased Approach alternatives), or new road construction (Road North/Bridge South Alternative). The Phased Approach alternatives (including the Preferred Alternative) would be 15 feet (4.6 meters) higher than the height assumed for the All Bridge Alternative (see Section 2.2.2). The nourishment component of the Phased Approach/Rodanthe Nourishment alternative would affect only the southern end of the Refuge. As such, the Parallel Bridge Corridor alternatives (in particular, the Phased Approach alternatives) would be less supportive of task force goals of

preserving the natural barrier island system, minimizing impacts to Hatteras Island, and maintaining access in a manner that has minimal impact on the environment.

Additional NC 12 hot spots are located south of Rodanthe. The selection of any of the replacement bridge corridor alternatives as the preferred alternative would not preclude any alternatives at the other hot spots, nor necessitate the development of additional alternatives.

4.12.6.2 Impacts Associated with Changed Access within the Pea Island National Wildlife Refuge and Cape Hatteras National Seashore

With a replacement bridge within the Pamlico Sound Bridge Corridor, the officials of the Refuge and the Seashore plan to reassess their approach for access within the Seashore north of Rodanthe and the Refuge. Dare County officials view highway access within the Refuge as an important contributor to the Dare County economy. As described in Section 3.5, visitors rely on NC 12 to reach various recreational activities within the Seashore and the Refuge on the 11.8 miles (19.0 kilometers) of Hatteras Island that is north of Rodanthe. These activities include fishing, cycling, hiking, walking, and birding. A replacement bridge within the Parallel Bridge Corridor would leave a paved road or bridge the full length of the Refuge north of Rodanthe. The Nourishment Alternative would result in no changes in access. The Road North/Bridge South Alternative would alter access by virtue of its new location; however, access from NC 12 to any part of the Refuge would be available except at the southern end of the project where a bridge would take NC 12 out of the Refuge and into Pamlico Sound. The bridges associated with the All Bridge Alternative would limit access to three access points. The bridges associated with the two Phased Approach alternatives (including the Preferred Alternative) would limit access to the Refuge to a greater extent than any of the other Parallel Bridge Corridor alternatives. Two access points would be provided (see Section 4.5.3.1).

Although the Pamlico Sound Bridge Corridor would bypass the portion of the Seashore north of Rodanthe and the Refuge, some type of access to this portion of the Seashore would be maintained for recreational users by the Refuge.

4.12.6.3 Impacts Associated with US Army Corps of Engineers Dredging

A replacement bridge within the Pamlico Sound Bridge Corridor would make navigation channel dredging operations easier to undertake and could reduce the frequency and size of dredging operations from what is required today. The proposed bridge in the Pamlico Sound Bridge Corridor and its navigation zone would be west of Oregon Inlet in Pamlico Sound where sand movement is less. This change alone could reduce both the amount of dredging required to maintain a channel through Oregon Inlet, as well as the associated impacts to the bottom of Oregon Inlet and Pamlico Sound.

The USACE currently maintains the Oregon Inlet Channel/Old House Channel. Movement of Oregon Inlet over the life of the proposed bridge in the Pamlico Sound Bridge Corridor could shift the natural channel gorge (i.e., the deepest location) to the Davis Channel area. This eventuality, and its effects on channel dredging in the long-term, would be addressed in conversations with the USACE as it relates to the Pamlico Sound Bridge Corridor. The NCDOT's goal is to place the navigation zone of a bridge in the Pamlico Sound Bridge Corridor in a location that facilitates channel maintenance over the full life of the proposed bridge, which could be up to 100 years.

A replacement bridge within the Parallel Bridge Corridor also would make navigation dredging operations easier to undertake. With most Parallel Bridge Corridor alternatives' crossing of Oregon Inlet, the proposed bridge's navigation zone would include a series of navigation spans across Oregon Inlet for a distance of up to approximately 5,000 feet (1,524 meters). The long navigation zone would allow the dredged channel to move with the natural inlet gorge under the bridge. The navigation zone across Oregon Inlet would be 3,300 feet (1,006 meters) with the two Phased Approach alternatives (including the Preferred Alternative), thus offering less flexibility for the USACE to move the dredged channel as the natural channel moves south, which it tends to do. The shorter distance is necessitated by the inclusion of ramps down to the north end of Hatteras Island from the Phased Approach alternatives' bridges. Since the Parallel Bridge Corridor is in Oregon Inlet and the terminal groin would remain in place, the long navigation zone also would take into account the possible shift of the natural channel gorge to the Davis Channel area.

4.12.6.4 Effect to (Former) US Coast Guard Station Preservation

A replacement bridge in the Pamlico Sound Bridge Corridor has raised questions regarding the effect of this change on access to the (former) US Coast Guard Station at the north end of Hatteras Island. Refuge officials intend to maintain some type of public access within the Refuge, including access to the (former) US Coast Guard Station. The NCDOT would be willing to participate in the development of alternate access plans, and it would invite the SHPO to participate. If the alternate access provided by the USFWS and the NPS is found by the SHPO to contribute potentially to the further neglect of the (former) US Coast Guard Station, the NCDOT would help ensure this potential impact is adequately mitigated. With the Pamlico Sound Bridge Corridor, such mitigation would not include retaining NC 12 through the Refuge.

The proposed demolition and removal of Bonner Bridge has raised the question of whether the demolition would limit opportunities for relocating the (former) US Coast Guard Station to a site north of Oregon Inlet (should that be preferred over relocating it to the south), since no easy way to move the structure to a site north of Oregon Inlet would remain. If the Pamlico Sound Bridge Corridor had been selected as the Preferred Alternative, NCDOT would not plan to demolish Bonner Bridge until the future disposition of the (former) US Coast Guard Station was resolved. However, given the poor condition of Bonner Bridge, consideration would have had to be given to whether the weight of the (former) US Coast Guard Station could be safely borne by Bonner Bridge before relocation across the bridge could take place.

A replacement bridge in the Parallel Bridge Corridor would retain NC 12 through the Refuge and, if relocated to a site north of Oregon Inlet, the (former) US Coast Guard Station could be moved either across the replacement bridge or by barge as discussed in Section 4.4.1.2 under "(Former) Oregon Inlet US Coast Guard Station." The retention of the terminal groin, required by all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative), would allow the Station to remain on its current site, if desired by its owners. If it remains at its current site, road access to the (former) US Coast Guard Station would remain with all of the Parallel Bridge Corridor alternatives.

4.12.6.5 Future Disposition of the Terminal Groin

With a replacement bridge in the Pamlico Sound Bridge Corridor, the terminal groin would no longer be needed for bridge protection, since the southern bridge terminus would no longer be at the north end of Hatteras Island. If future circumstances—in association with the USFWS permit for the terminal groin or trends in Oregon Inlet and Hatteras Island movement—were to deem it prudent to remove the terminal groin, Oregon Inlet would be expected to revert to historical

migration trends (see Section 3.6.3). For example, it is anticipated that if the terminal groin were removed three years after a bridge in the Pamlico Sound Bridge Corridor opens, and the inlet began to migrate in the same linear fashion as it did before the groin was built, then 50 years after the proposed bridge opens, Oregon Inlet would migrate between 4,600 and 8,000 feet (1,400 and 2,440 meters) south. After 75 years, the inlet would have migrated between 6,900 and 10,300 feet (2,100 and 3,140 meters) south. This example likely represents a "worst-case" situation. Such a change would affect Oregon Inlet channel maintenance strategies, result in the loss of the site of the (former) US Coast Guard Station, and the loss of wildlife habitat. It would be consistent with the desire of officials of the Seashore and the Refuge, who oversee the area and its habitat, to let natural processes take their course. NCDOT has no current plans to remove the terminal groin if a replacement bridge in the Pamlico Sound Bridge Corridor is constructed. If USFWS officials ask the NCDOT to remove the groin following completion of the demolition and removal of Bonner Bridge, the NCDOT and representatives of the USFWS would assess the impacts of groin removal in a separate environmental study, as needed, prior to any final decision to remove the terminal groin.

With the Parallel Bridge Corridor, the terminal groin would be necessary to protect the southern terminus of the new bridge from the natural southward movement of Oregon Inlet. In the case of the Phased Approach alternatives (including the Preferred Alternative), the groin would be needed at least until Phase II of the project is completed. The NCDOT would seek a new permit from the Refuge to protect the new bridge. The current permit for the terminal groin is only for "the existing Herbert C. Bonner Bridge." The groin would need to remain in place for the life of the new bridge in the Parallel Bridge Corridor, except with the Phased Approach alternatives. The USFWS has indicated that the selection of a Parallel Bridge Corridor alternative as the Preferred Alternative will not guarantee the issuance of the new permit.

4.12.6.6 Relocation of Utilities in Response to Shoreline Erosion

Telephone and electrical lines are present in the project area and roughly parallel NC 12. Like NC 12, these utility lines also are placed in jeopardy by shoreline erosion. Thus, it is reasonably foreseeable that these lines would need to be moved one or more times between now and the design year of this analysis, 2060. This section discusses in general terms potential utility relocation scenarios and how they might add to the impacts assessed for the replacement bridge corridor alternatives. (Also see Section 4.1.6.8 and Section 4.1.6.10.)

Pamlico Sound Bridge Corridor Alternatives

These alternatives would not provide a connection to the north end of Hatteras Island. In this case, telephone and electrical lines would be placed on the new bridge or adjacent to the new bridge in Pamlico Sound. The costs reflected in Table 2-11 and Table 2-12 and listed in Section 4.1.6.8 and Section 4.1.6.10 assume that the telephone lines are placed on the Pamlico Sound Bridge Corridor bridge, and electrical lines are placed on poles adjacent to the bridge, which is expected to be the least expensive approach. Bottom disturbance would be associated with placing electrical line poles in the sound. These utility lines would connect back into Hatteras Island at Rodanthe. Lines in Rodanthe along NC 12 would likely be moved back as needed as a result of shoreline erosion. Given the developed nature of Rodanthe, substantial environmental impacts would not be expected from pole and line relocation in Rodanthe. Lines would be removed from the Refuge except as needed for Refuge facilities. The extent of the lines remaining in the Refuge would be up to Refuge officials. Given that Refuge facilities using telephone and electricity also would be lost to future beach erosion, the extent of the relocation of these lines in the Refuge would depend upon where the Refuge chooses to relocate its facilities.

Parallel Bridge Corridor with Nourishment Alternative

This alternative would protect NC 12 from shoreline erosion so that it can remain in its existing easement. Since electrical and telephone lines are west of NC 12 (except for at the southern end of the project area in Rodanthe), the nourishment associated with this alternative also would protect the utility lines. They would not need to be relocated with associated impacts.

Parallel Bridge Corridor with Road North/Bridge South, All Bridge, and Phased Approach Alternatives (Including the Preferred Alternative)

All three of these alternatives would involve building new bridges between Rodanthe and Oregon Inlet. Only the Road North/Bridge South Alternative also would involve road relocation at grade. Because of the high cost of placing electrical lines on bridges (approximately $2.5 million per mile in 2006 dollars) and the comparatively low cost (approximately $123,000 per mile over upland) of relocating electrical lines on poles, it is assumed likely that with these alternatives, the electrical lines would be relocated on poles on land and generally independent of the Bonner Bridge replacement project (with the sole exception of placing both utilities on the new bridge over Oregon Inlet). In the case of telephone lines, the cost per mile on a bridge is approximately $20,000 per mile versus $50,000 per mile on land, so in the case of the telephone lines, relocation on the proposed bridges could be advantages to the telephone company depending on the cost of line maintenance. Utility relocation on land could be accomplished in three ways:

- Moving the Utilities Back from the Ocean Multiple Times on Upland. As the shoreline erodes, sand overwash will fill wetlands near the shore creating new upland. Poles could be moved back as needed without the need for poles or equipment to pass through or use Refuge wetlands. Utility company equipment would have to drive on Refuge uplands to reach their lines to the extent that NC 12 is on bridges or has been relocated on road beyond the forecast 2060 high erosion shoreline as in the case of the Road North/Bridge South Alternative. This approach is assumed in the cost estimates reflected in Table 2-11 and Table 2-12 and are listed in Section 4.1.6.8 and Section 4.1.6.10.

- Moving Utilities Back to a Point Beyond the Forecast 2060 High Erosion Shoreline Once. In this particular case (with the exception of the road sections of the Road North/Bridge South Alternative) utility lines likely would be relocated into wetlands with associated higher relocation costs, construction impacts to wetland and upland habitat associated with bringing in equipment to erect the new lines, and long-term equipment movement impacts associated with inspection and maintenance.

- Erect New Lines in the Road North Easement. In the road section of the Road North/Bridge South Alternative, erecting new lines within the new NCDOT easement so that impacts occur for both activities (road and utility relocation) at the same time, and equipment can use the relocated road for maintenance and inspection access.

Thus, with these three alternatives repeated impacts to uplands and/or wetlands would occur in the Refuge between now and 2060, with associated disturbances to wildlife. In Rodanthe, impacts would be similar to those described above for the Pamlico Sound Bridge Corridor. The exact approach to utility relocation would likely be determined by utility and Refuge preferences, negotiations with the NCDOT for utilities placed on bridges or in an NCDOT easement, total cost to the utilities, and opportunities to spread costs over time.

4.12.6.7 Cumulative Effect of Habitat Loss or Change on the Ecological Integrity of the Outer Banks

The project area includes approximately 13 percent of the length of North Carolina's Outer Banks (see Section 4.12.4.8). Approximately 76.8 miles of 126.7 miles (123.6 to 203.9 kilometers), or 61 percent, of the length of the Outer Banks remains in state and federal ownership and is generally not developed. The project area includes 19 percent of that 76.8-mile (123.6-kilometer) length. From an ecological standpoint, this area is one of the most important portions of the Outer Banks. First, it is a large area of undeveloped habitat. Secondly, the presence of a National Wildlife Refuge provides an extensive area where land use decisions are based on maintaining natural systems.

Total habitat losses associated with the project are described in Section 4.7. General loss of habitat varies from 9.53 acres (3.86 hectares) with the Parallel Bridge Corridor with Phased Approach/Rodanthe Nourishment Alternative to 91.60 acres (37.07 hectares) with the Parallel Bridge Corridor with Road North/Bridge South Alternative. The majority of the lost area associated with the Phased Approach alternatives (including the Preferred Alternative) is currently occupied by existing NC 12 and Bonner Bridge. Of the Parallel Bridge Corridor alternatives, the Phased Approach alternatives would result in the loss of the least amount of undisturbed Outer Banks habitat when built. The Pamlico Sound Bridge Corridor alternatives would offer both the removal of NC 12 from the Refuge, as well as the removal of the disturbances to Refuge wildlife, including those related to NC 12 storm maintenance and traffic operations.

As indicated in Section 4.12.4.8, only about 10 percent of the Outer Banks shoreline can be considered undisturbed or potentially undisturbed by development and beach driving. Almost all of that area (92 percent) is in the project area. Although undisturbed by development or beach driving, the shoreline in the project area is disturbed by a human made dune system and the maintenance of the system in association with maintaining NC 12. The Pamlico Sound Bridge Corridor would eliminate the current disturbance associated with NC 12 maintenance and allow natural processes to occur. The Parallel Bridge Corridor Alternatives would affect this scarce, undisturbed, and protected beach as follows:

- Nourishment Alternative. The nourishment program and associated dune building would continue to disturb the shoreline (preventing natural erosion and overwash processes from taking place), although the frequency of emergency disturbances would be reduced by a wider beach and a stronger dune line.

- Road North/Bridge South. NC 12 would be moved away from the shoreline as a new paved road or placed on a bridge at a point at least 230 feet (70.1 meters) west of the 2060 high erosion shoreline. The existing dunes along the oceanside of NC 12 would not be rebuilt (i.e., they would be allowed to erode naturally). However, three 10-foot (3-meter) high dunes, totaling 2,100 feet (640 meters) in length would be built east of and near the new road, but not immediately. They would be built as needed as the shoreline erodes towards the relocated road. The first one is expected to be built by 2030. The dunes, once built, would resist or prevent overwash. The relocation of the road, while allowing for natural shoreline movement, would disturb new natural habitat in the refuge (as noted above), particularly wetlands, and associated wildlife. The pavement of existing NC 12 would be removed and the land replanted.

- All Bridge. NC 12 would be moved away from the shoreline and placed on a bridge at a point at least 230 feet (70.1 meters) west of the 2060 high erosion shoreline. The existing dunes along the oceanside of NC 12 would not be rebuilt (i.e., they would be allowed to erode

naturally). The relocation of the road, while allowing for natural shoreline movement, would disturb new natural habitat in the refuge (as noted above), particularly wetlands, and associated wildlife. The pavement of existing NC 12 would be removed and the land replanted.

- Phased Approach/Rodanthe Bridge Alternative (Preferred). This alternative would place NC 12 on a bridge in the existing right-of-way resulting in the least initial direct impact to natural habitat. Natural shoreline processes would be allowed to take place. The shoreline would erode underneath the bridge. Ultimately the project would have portions over the beach and in the ocean for distances shown in Table 4-23. The presence of the bridge in this location would adversely impact the shoreline from the perspective of its natural appearance (see Section 4.3.2), recreational use (see Section 4.5.3), the outcome of coastal processes along the beach (see Sections 4.6.8.3 and 4.6.8.5), and wildlife (see Sections 4.7.5.2, 4.7.6.6, and 4.7.6.7), including protected species that use beach habitat (see Section 4.7.9).

- Phased Approach/Rodanthe Nourishment. This alternative would have impacts similar to the Phased Approach/Rodanthe Bridge except in the nourishment area near Rodanthe, where the affects on the shoreline at the southern end of the Refuge would be those of the Nourishment Alternative.

4.13 Construction

Construction in the Pamlico Sound Bridge Corridor or the Parallel Bridge Corridor and demolition and removal of Bonner Bridge would be governed by:

- NCDOT's *Standard Specifications for Roads and Structures* (NCDOT, July 2006, or as current at the time of construction); and

- American Association of State Highway and Transportation Officials' (AASHTO) *Standard Specifications for Highway Bridges* (AASHTO, 2002, or as current at the time of construction).

Separate contracts would be issued for construction of the proposed project and demolition and removal of Bonner Bridge with the Pamlico Sound bridge. With an Oregon Inlet bridge, demolition could be within the same contract as construction. Mechanisms would be put in place to maintain traffic flow; minimize air quality, noise, and construction lighting impacts; manage waste disposal; protect surrounding natural resources; control erosion; and handle any accidental waste spills. Affected geodetic survey markers in the project area would be properly relocated. Specifics related to these construction and demolition issues are presented in the sections that follow.

4.13.1 Traffic Maintenance

Traffic would be maintained on NC 12 and Bonner Bridge throughout the construction of the replacement bridge corridor alternatives. With two exceptions described below, the only opportunity for construction to interfere with NC 12 traffic would be when new bridges or roads are connected into existing NC 12. If this part of the construction process coincides with the peak visitation period, two lanes of traffic would be maintained during the connections. In order to maintain traffic with the Parallel Bridge Corridor with All Bridge Alternative, a construction easement adjacent to NC 12 would be obtained and temporary pavement built south of the Refuge's ponds where the new NC 12 bridge would be built within the existing NC 12 easement for approximately 0.9 mile (1.4 kilometers).

The greatest challenge to maintaining traffic on NC 12 would be at the southern terminus of the Oregon Inlet bridge with the Parallel Bridge Corridor with Nourishment and with Phased Approach alternatives (including the Preferred Alternative). It is anticipated that the southern end of the existing Bonner Bridge would be partially removed for the purposes of constructing a temporary traffic maintenance bridge. The two phased approach alternatives also would be built with the existing NC 12 easement for their full length on Hatteras Island. A new easement permit, therefore, likely would not be needed from the USFWS.

With the Nourishment Alternative, the last two or three spans of the new bridge would be built over the final spans of Bonner Bridge so that the Bonner Bridge easement in the Refuge can be used by the new bridge. During construction, periodic short-term closings of NC 12, presumably at night and in the off-season, would be needed at a minimum as new precast bridge components are maneuvered into position over or adjacent to Bonner Bridge. Once a component is placed, Bonner Bridge would be reopened to traffic until contractors are ready to place the next component. On land, where Bonner Bridge ends and the approach road to Bonner Bridge begins, a temporary detour would divert NC 12 traffic out of the existing easement.

With the two Phased Approach alternatives (including the Preferred Alternative), two lanes of traffic would be maintained on NC 12 via temporary roads and a short bridge, as described in Section 2.10.

Brief periods of delay and disruption that result from construction vehicles operating on NC 12 could be encountered by motorists. Most of the bridge components with the replacement bridge corridor alternatives would be brought to the construction site by barge. The construction contractor would be required to meet the traffic maintenance requirements of NCDOT's *Standard Specifications for Roads and Structures* (NCDOT, July 2006, or as current at the time of construction). A traffic control plan would be developed, and special care would be taken to clearly delineate a safe travelway for traffic.

4.13.2 Air Quality

During construction, all materials resulting from clearing and grubbing and demolition would either be removed from the project site, burned, or otherwise disposed of by the contractor. Any burning would be done in accordance with applicable local laws and ordinances and regulations of the North Carolina SIP for air quality in compliance with 15 NCAC 2D.0520. Burning would be conducted only away from nearby buildings and only when atmospheric conditions do not create a hazard to the public. Any burning activities would be supervised at all times. In addition, appropriate measures would be taken to reduce dust generated by construction activities. The contractor would ensure that fugitive dust would be controlled at all times for the protection and comfort of motorists and area residents.

4.13.3 Noise

Construction noise varies greatly with the type of equipment in use and the phase of construction activity. Noise levels near a construction project therefore fluctuate greatly from day to day and hour to hour. The primary noise effect would be from the operation of construction equipment. Construction noise sources include truck and equipment engines; equipment noise from scraping, ripping, and excavating; back-up alarms; the slam of truck tailgates as asphalt truckers knock the last bit out of their dump beds; impact wrenches on structural bolts for bridges; rock drilling; pile driving; and blasting.

High noise levels of impact pile driving and combustion-engine-powered equipment usually are the main contributors to bridge construction equipment noise levels. It has been documented that the typical noise levels produced by pile driving operations range from 82 to 105 dBA regardless of the pile driving technique implemented. For proposed bridge substructures (foundation and support for the superstructure), precast piles are planned. Over water, these piles could be jetted (high-pressure water is used to move sand aside so the pile can drop into place) or, in some cases, driven (hit with a large hammer or vibrated to drive the piles into the ground). With jetted piles, it is common to use a pile driver to seat the pile (to bring it to its final stopping point). Over land, bridge piles could be driven or inserted into drilled shafts. In general, construction noise impacts within the Pamlico Sound Bridge Corridor and for the Oregon Inlet bridge in the Parallel Bridge Corridor would be minimal, since much of the effort would occur in open water, away from human activities. Bridge construction operations could take place 24 hours a day so that the proposed bridge could be opened to traffic within the construction timeframe as discussed in Section 2.10.1.3. Noise impact would be greatest at:

- The campground and fishing center at the northern terminus of the proposed Pamlico Sound and Oregon Inlet bridges (on Bodie Island);

- In the community of Rodanthe: at the southern terminus of the Pamlico Sound Bridge Corridor; at the southern terminus of the Rodanthe area bridge associated with the Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives; and along the length of the Phased Approach alternatives (including the Preferred Alternative); and

- Bridge foundation construction locations on Hatteras Island for the Parallel Bridge Corridor with All Bridge and Phased Approach alternatives (including the Preferred Alternative), where there would likely be disturbances to Refuge users and waterfowl, particularly if bridge piles are driven.

Control of construction noise at the source is the most effective approach to reducing noise. Several measures can be utilized in order to minimize noise resulting from construction activities. Such measures include, but are not limited to, the following:

- Minimizing the use of impact hammers to drive bridge piles into place;

- Requiring that construction equipment comply with noise standards adopted by the Occupational Safety and Health Administration (OSHA);

- Requiring construction equipment to have effective mufflers, have efficient silencers on air intakes of equipment, and to be properly maintained; and

- Placing continuously operated diesel-powered equipment, such as compressors and generators, in areas as far as possible from or shielded from noise-sensitive locations.

Other noises are best handled by indirectly managing the activities through decibel restrictions. Construction operations and associated noise generally would be restricted to daytime hours when near noise-sensitive receptors.

4.13.4 Lighting

Because construction activities could occur 24 hours a day, construction areas could be lit to daylight conditions at night. Night lighting would not occur near turtle nesting areas with any of the replacement bridge corridor alternatives.

The NCDOT would work with the NCDENR Division of Marine Fisheries and the National Marine Fisheries Service to determine if there are areas in the Pamlico Sound and Oregon Inlet where night lighting would need to be avoided or limited. Night lighting would not be used close to areas where people sleep, including the campground at the northern terminus of the project and in the Rodanthe area.

4.13.5 Waste Disposal

Excavated, dredge, and fill waste material generated by the replacement bridge corridor alternatives generally would be disposed of using one or more of the techniques that have been used regularly in the Oregon Inlet area in past years: open water disposal, diked as well as undiked disposal areas, and beach nourishment. Different disposal methodologies, as well as the type of material to be deposited, would have different potentials for environmental impact. The USACE has found that material dredged from the Ocean Bar channel at Oregon Inlet is more than 95 percent sand (USACE, 1980c) and has indicated that this would be the case for material dredged in connection with the replacement bridge corridor alternatives. A representative of the USACE has expressed interest in having suitable sand pumped onto Hatteras Island as a part of beach stabilization efforts. (Personal communication, August 15, 1991, and October 24, 2003, Howard Varnam, USACE Navigation Branch, Wilmington, NC.) If suitable (e.g., proper particle size, mineralogical composition, etc.) for beach nourishment, dredged material could be used a part of the first round of beach nourishment with the Parallel Bridge Corridor with Nourishment Alternative.

The advantages and limitations of these different scenarios are:

- Open Water Disposal. In the past, open water disposal has been used to remove sediments from dredging sites, including the Ocean Bar channel at Oregon Inlet. This type of disposal involves the discharge of slurry into surrounding waters. It is used most often in areas where no upland site is available. This method potentially would produce the most visible and greatest impact to water quality, especially when disposal sites are near critical habitats (i.e., SAV, oyster beds, and nursery areas). Critical habitats would be avoided. If dredged materials are compatible with the sediments of the disposal site, the site should revert back to its original state. The material to be dredged in connection with the replacement bridge corridor alternatives is expected to be suitable for open water disposal. Thus, it can be recycled back into the system.

- Undiked Disposal Area. The practice of undiked disposal has been used commonly throughout the coastal region over the years. With this method, dredged material is placed in unconfined disposal areas. When dredged materials are mostly sands (as is the case in the project area), the material can be directed roughly into defined areas within the site. When materials are of smaller fractions, the confinement is decreased even more, and the dredged material spreads over a greater area. The impacts to the water quality of the site depend on the type of material dredged. Higher sand concentrations cause little or no increase in turbidities, whereas finer sediments remain suspended longer and cause short-term and temporary turbidity-related impacts.

- Re-nourishment of Dredged Disposal Islands. Dredged materials might be suitable for use in re-nourishment of existing dredged material islands. Dredged material islands exist near the project area (see Figure 3-7) and are used as nesting sites for colonial waterbirds. An interagency coordinating committee has been established to facilitate the cooperation needed to successfully manage North Carolina's colonial waterbirds through activities such as depositing dredged materials in the coastal zone. During disposal of new material, nesting sites might be temporarily or permanently lost, according to the character and placement of dredged material. Additional dredged material islands exist west of the project site. They have unused capacity and might be available for placement of some dredged material. (Personal communication, August 15, 1991 and October 24, 2003, Howard Varnam, USACE Navigation Branch, Wilmington, NC.)

- Beach Nourishment. Beach nourishment is another alternative to disposal. Dredged material consisting of clean sands of the correct particle size is added to beach deposits to replace sand lost by erosion. The state requires that dredged material taken from close to shore to be deposited back onto the beaches. (Personal communication, October 24, 2003, Howard Varnum, USACE, Navigation Branch, Wilmington, NC.) Suitable material occurs within the project area. The USACE has found that material dredged from the Ocean Bar channel at Oregon Inlet is suitable for beach nourishment. The material along Bonner Bridge also could be suitable for beach nourishment, according to the USACE. (Personal communication, August 15, 1991 and October 24, 2003, Howard Varnam, USACE Navigation Branch, Wilmington, NC.) Currently, the majority of material dredged around Oregon Inlet (1,000,000 cubic yards [760,000 cubic meters] dredged in 2002) is deposited onto Hatteras Island. Special use permits would be required from the USFWS and the NPS if dredged material were used to re-nourish Hatteras Island's beaches or as a part of initial nourishment and dune building activities for the Parallel Bridge Corridor with Nourishment Alternative. Beach compaction would be prevented further by depositing dredged materials below the mean high-tide line. In addition, development activities, which can include nourishment, generally are not allowed during the nesting season from May 1 to November 15 to minimize disturbance to turtles. (Personal communication, October 31, 2003, Matthew Godfrey, State Sea Turtle Coordinator, North Carolina Wildlife Resources Commission.)

- Upland Disposal. Upland areas enclosed by earthwork dikes also have been used for disposal of coastal dredged material. Confinement allows settlement of the solids in the slurry and controls runoff of slurry water. Disposal of dredged material in this fashion usually results in a drastic change in land use. The short-term impacts, a result of diking and filling, involve removal of existing flora and fauna. Upland vegetation is covered by dredged material or killed from the salt. An island does exist near Wanchese (Island H on Figure 3-7) that can be used for diked disposal. The material in this area is not sand, and sand disposed there cannot be allowed to run off into the water. (Personal communication, August 15, 1991 and October 23, 2003, Howard Varnam, USACE Navigation Branch, Wilmington, NC.) During material disposal, nesting sites might be lost temporarily or permanently, according to the character and placement of dredged material.

The nondiscretionary measures outlined in the Biological and Conference Opinions (USFWS, 2008) for the Phased Approach/Rodanthe Bridge Alternative (Preferred) related to piping plovers specify that "all dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission." The NCDOT is committed to implementing this measure. The appropriate location for disposal would be determined based on the character of the materials

dredged, the availability of disposal sites, and coastal conditions near the time of construction. The information needed for NCDOT to develop a disposal plan would be obtained during the USACE permit preparation process. The disposal of excess material would be the responsibility of the contractor, who would be required contractually to handle and dispose of the material in accordance with NCDOT's Standard Specifications for Roads and Structures (NCDOT, July 2006, or as current at the time of construction), permit requirements, and local, state, and federal laws.

Any toxic and hazardous materials would be handled and used in accordance with package labels and manufacturers' directions. Wastes would be segregated, labeled, and stored in a manner that would prevent their release into the environment from an accident or spill. The contractor would dispose of these materials and their containers in accordance with applicable state and federal regulations.

4.13.6 Construction Access

4.13.6.1 Dredging

The contractor may elect to use barge-mounted equipment. It is anticipated that, in locations where the water depth is less than 6 feet (1.8 meters) deep, dredging would be required such that sufficient water depth is provided to float and move loaded construction barges. It was assumed that dredging would be to a depth of 8 feet (2.4 meters), which is deeper than absolutely necessary to float and move construction barges, because of the dynamic coastal conditions that exist in the project area. Tidal water movement, potential storm conditions, and complex sediment transport would have the tendency to fill back in dredged channels over a short period of time. Therefore, dredging deeper than absolutely necessary would alleviate the need to frequently re-dredge the channel.

It is assumed that barges could be loaded with crawler cranes along with major bridge components such as piles, formwork, girder sections, and other equipment. These components and equipment would likely be delivered by barge from the fabrication yard to the work barges.

The contractor would coordinate with NCDOT, USACE, USFWS, NMFS, and NCDENR in developing its dredging technique and disposal plan that would minimize harm to natural resources.

General guidelines for developing a detailed dredging plan would be prepared by the contractor and submitted for NCDOT review and approval. The following are dredged channel dimensions and locations:

- Maximum channel width = 120 feet (36.6 meters);
- Maximum channel depth = 8 feet (2.4 meters);
- Channel length shall be kept to the minimum dimension deemed practicable; and
- Dredging is prohibited in areas of SAV.

Dredging techniques also would require approval. The two basic techniques include pipeline or clamshell dredging and hopper dredging. However, hopper dredging would be prohibited.

4.13.6.2 Haul Roads and Work Bridges

The contractor could use haul roads and work bridges for access to facilitate construction of the replacement bridge corridor alternatives. Delivery trucks and crawler cranes would use the haul roads and/or work bridges to deliver and erect major bridge components such as piles, formwork, and girder segments. The potential use of a haul road is anticipated only west of Bodie Island with a Parallel Bridge Corridor alternative. The contractor would coordinate with the NCDOT, the USACE, the USFWS, the NMFS, and the NCDENR in its development of a site access plan that would minimize harm to natural resources. For example, haul roads would be prohibited in SAV areas.

Although a final approach would be developed by the contractor, it is anticipated that haul roads would consist of a main road a maximum of 65 feet (19.8 meters) wide that is aligned parallel to the new Oregon Inlet bridge alignment with pier access roads, or fingers, that are aligned perpendicular to the main road. The pier access roads would be a maximum of 40 feet (12.2 meters) wide and could be at each proposed pier location within the length of the haul road.

The following are requirements would be used for construction and removal of haul roads:

- Haul road material would be approved by the permitting agencies and NCDOT and could consist of fill obtained from the inlet or sound;
- Turbidity curtains or other means would be implemented to minimize disturbance of the sound bottom during placement of fill;
- Fill used for haul road construction would be placed on geotextile fabric;
- Side slopes of haul roads would be constructed with geotextile fabric to minimize erosion;
- Haul roads would be constructed to prevent leakage or seepage of liquid materials associated with construction equipment from entering adjoining waters or wetlands;
- Haul roads would be removed and disposed of in accordance with NCDOT and permitting agency requirements; and
- After a haul road is removed, the entire area covered by the haul road would be re-vegetated as directed by the NCDOT.

As a result of haul roads or dredging not being used in areas of SAV, work bridges would be needed at some locations along the construction of the new bridges in the inlet or sound. Structural and geotechnical design of the work bridge components would be in accordance with the latest edition of the NCDOT Structure Design Manual. The contractor would design the work bridges for actual construction equipment live loads and would coordinate the work bridge design with the proposed bridge erection sequence. A work bridge design also would comply with OSHA requirements. The following are requirements for construction and removal of work bridges:

- Work bridge materials would be coordinated with the permitting agencies and the NCDOT;
- Turbidity curtains or other means would be implemented to minimize disturbance of the sound bottom during placement of work bridge foundations;

- Work bridges would be constructed to minimize or prevent leakage or seepage of liquid materials associated with construction equipment from entering adjoining waters or wetlands; and

- Work bridges, including their foundations, would be removed and disposed of in accordance with NCDOT and permitting agency requirements.

4.13.7 Natural Resource Protection

Protection of the natural resources within the project area would involve implementing environmental safeguards during all stages of the project from planning through construction and demolition. Separate contracts would be issued for construction of the proposed project in the Pamlico Sound Bridge Corridor and demolition and removal of Bonner Bridge. With an Oregon Inlet bridge, demolition could be within the same contract as construction.

The first opportunity for protection of the natural resources and also the most successful is avoidance of sensitive areas. For example, the locations of SAV areas and a 10 foot (3.05 meters) buffer would be identified and delineated for avoidance. These areas would be monitored for changes every other month by the contractor. Updated SAV locations would be submitted by the contractor to NCDOT and the permitting agencies for review. Modifications to the construction plans, such as demolition plans, and site access plans may be required depending on how the SAV locations change over the duration of the construction.

The Pamlico Sound Bridge Corridor would avoid most of the sensitive areas identified in the project area and activities that would produce potentially adverse impacts. A work bridge would be used when construction equipment barges are over SAVs and water is not deep enough to float the barge without dredging. The Parallel Bridge Corridor would affect a much larger area of sensitive natural resources than the Pamlico Sound Bridge Corridor, as documented in Section 4.6.8. Oregon Inlet bridge construction in the Parallel Bridge Corridor would include construction of a temporary haul road, dredging or a work bridge behind Bodie Island. The Road North/Bridge South and All Bridge alternatives include bridges or roads over wetland and upland wildlife habitat in the Refuge for approximately 7 miles (11.3 kilometers). These bridges would be built from a work bridge.

Appropriate BMPs applicable to construction and maintenance for protection of surface waters, wetlands, and upland habitat would be used to control erosion, sedimentation, and stormwater runoff (see Section 4.13.8). All waters in the project area are classified as SA waters (Class A salt waters) with a supplemental classification of HQW. The most stringent application of the BMPs is expected where highway projects affect receiving waters of special designation, such as HQW (NCDOT, August 2003). The NCDOT's design standards for sensitive watersheds are applicable to the project because of the SA/HQW classification. If requested by appropriate agencies, attempts would be made to reduce dredging activities associated with Pamlico Sound or Oregon Inlet bridge construction as much as possible during the spring to avoid minor effects to the fisheries resources. Dredging plans and disposal of dredged material and construction within the Refuge would be coordinated with appropriate agencies to avoid affecting nesting by colonial waterbirds and sea turtles and to minimize other wildlife impacts. The nondiscretionary measures outlined in the *Biological and Conference Opinion*s (USFWS, 2008) for the Phased Approach/Rodanthe Bridge Alternative (Preferred) related to piping plovers specify that "all dredge spoil excavated for construction barge access must be used to augment either existing dredge-material islands or to create new dredge-material islands for use by foraging plovers. This

must be accomplished as per the specifications of the North Carolina Wildlife Resources Commission." The NCDOT is committed to implementing this measure.

For access to Bonner Bridge for demolition equipment, a work bridge likely would be used over wetlands on Bodie Island. Use of a temporary haul road could be requested if it is demonstrated that such access would not result in permanent impacts to marsh communities because these communities do not have an underlying organic subsoil, or if the cost of constructing and dismantling a temporary work bridge is so high that it would not be practicable to employ that methodology.

4.13.8 Erosion Control

North Carolina Administrative Code Title 15A, Chapter 4B entitled "Sedimentation Control" requires approval of a soil erosion control plan before land-disturbing activities can begin. The NCDOT would prepare an erosion control plan.

The control plan must identify critical areas subject to severe erosion, limit the size of the area exposed at any one time, limit the time exposed, control water runoff, prevent off-site sedimentation damage, and manage stormwater runoff. Impacts resulting from erosion and sedimentation likely would be kept to a minimum by employing BMPs such as silt check dams, silt fences, and silt basins. During construction of the proposed project and demolition and removal of Bonner Bridge (which would occur under a separate contract), appropriate improvement techniques would be employed, such as prompt establishment of appropriate grass species, sediment barriers, and proper grading of slopes in order to meet the standards set by the Sedimentation Pollution Control Act of 1973 as amended. These practices would include those in conformance with NCDOT's *Sediment and Erosion Control Program* and *Best Management Practices for Protection of Surface Waters*.

4.13.9 Waste Spill Contingency Planning

In the event of hazardous waste or oil spills, the contractor would follow the emergency response procedures established under the North Carolina Oil Pollution and Hazardous Substances Control Act of 1978, as amended. Immediately after discovery of a spill, the contractor would contact the Dare County Communications Center (911), which would alert the Dare County Emergency Management Office, appropriate fire departments, and other agencies or persons required under the County's emergency management plan and Title 3 of the Superfund Amendment and Reauthorization Act of 1986 (SARA). The contractor then would initiate cleanup of the spill as soon as possible.

The North Carolina Oil Pollution and Hazardous Substance Control Act applies to spills of oil and those chemicals listed in the Federal Clean Water Act, whether on the ground or in water bodies, including off-shore spills.

4.13.10 Geodetic Survey Markers

Geodetic survey markers in the project area would be properly relocated if affected.

4.14 Relationship between Long-Term and Short-Term Uses/Benefits

The local short-term impacts and the use of resources for any of the replacement bridge corridor alternatives would be consistent with the maintenance and enhancement of long-term productivity for Dare County and the State of North Carolina.

Bonner Bridge provides the only highway connection between Hatteras Island and the mainland; it is the only link between the Bodie Island and Hatteras Island portions of the Seashore. By providing a replacement crossing and maintaining NC 12 to Rodanthe, the replacement bridge corridor alternatives would provide regional benefits to the recreational and business community that outweigh the long-term adverse impacts associated with the construction of the project in a sensitive environment. With the replacement bridge corridor alternatives, direct motor travel service between Hatteras Island and the mainland via Bodie Island would continue uninterrupted, as would the delivery of goods and services from the mainland upon which island residents and visitors depend. The tourist and service-related industries of the region would be hindered by the reduction in access that would result from the No-Action Alternative.

The short-term impacts and use of resources in the construction of a Pamlico Sound Bridge Corridor project would be consistent with the maintenance and enhancement of the long-term productivity of Hatteras Island and the Seashore as defined by area plans. The proposed bridge in the Pamlico Sound Bridge Corridor would be consistent with the Refuge *Master Plan*'s goal of not moving the existing NC 12 alignment within the Refuge as the new alignment would bypass the entire Refuge. The proposed bridge also would be compatible with NPS and USFWS management policies to let natural processes of shoreline change take their course. Paved road access through the Refuge, as preferred by Dare County officials, however, would not likely continue with the Pamlico Sound Bridge Corridor. Refuge officials intend to provide an alternate type of access. The potential economic impact of this change is discussed in Section 4.1.5.

The short-term impacts and use of resources in the construction of a Parallel Bridge Corridor project would not be consistent with the maintenance and enhancement of the long-term productivity of the Refuge and the Seashore from the perspective of the goals of their respective plans discussed in the previous paragraph; however, the NPS and USFWS will be responsible for determining whether or not the Parallel Bridge Corridor alternatives (including the Preferred Alternative) are consistent overall with their respective plans. The Parallel Bridge Corridor alternatives would retain paved road access through the Refuge, as desired by Dare County officials, although the two Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) would provide only two points of access and the All Bridge Alternative would provide three. Although not an objective of Refuge officials, the Parallel Bridge Corridor with Nourishment Alternative would maintain the status quo for Refuge facilities, protecting the Refuge's ponds, Visitor Center, headquarters, and trails from the effects of future beach erosion (see Section 4.5).

4.15 Irreversible and Irretrievable Commitments of Resources

Implementation of any of the replacement bridge corridor alternatives would involve commitment of a range of natural, physical, human, and fiscal resources. Land used in the construction of any of the replacement bridge corridor alternatives would be considered an irreversible commitment

during the time period that the land is used for a highway and bridge facility. However, if a greater need arises for use of the land or if the bridge is no longer needed, the land could be converted to another use. At present, there is no reason to believe such a conversion ever would be necessary or desirable.

Considerable amounts of fossil fuels, labor, and highway/bridge construction materials (such as concrete and steel) would be expended. Additionally, large amounts of labor and natural resources would be used in the fabrication and preparation of construction materials. These materials generally are not retrievable. They are not, however, in short supply, and their use would not have an adverse effect on continued availability of these resources. Any construction also would require a substantial one-time expenditure of both state and federal funds, which would not be retrievable.

The commitment of these resources is based on the concept that residents in the immediate area, state, and region, as well as visitors to the area, would benefit by maintaining the quality of the current transportation system. These benefits would consist of continued accessibility, safety, and support of tourism. Such benefits are anticipated to outweigh the commitment of resources.

The No-Action Alternative would require the commitment of materials, labor, and funds to build, operate, and maintain a small-scale ferry operation.

Chapter 5

Final Section 4(f) Evaluation

5.0 Final Section 4(f) Evaluation

Section 4(f) of the Department of Transportation Act of 1966, as amended (49 *United States Code* [USC] 303), states that the US Department of Transportation (USDOT) may not approve the use of land from a significant publicly owned park, recreation area, or wildlife and waterfowl refuge, or any significant historic site, unless a determination is made that the project will have a *de minimis* impact or unless a determination is made that:

1. There is no feasible and prudent avoidance alternative, as defined in 23 CFR (*Code of Federal Regulations*) 774.17, to the use of land from the property; and

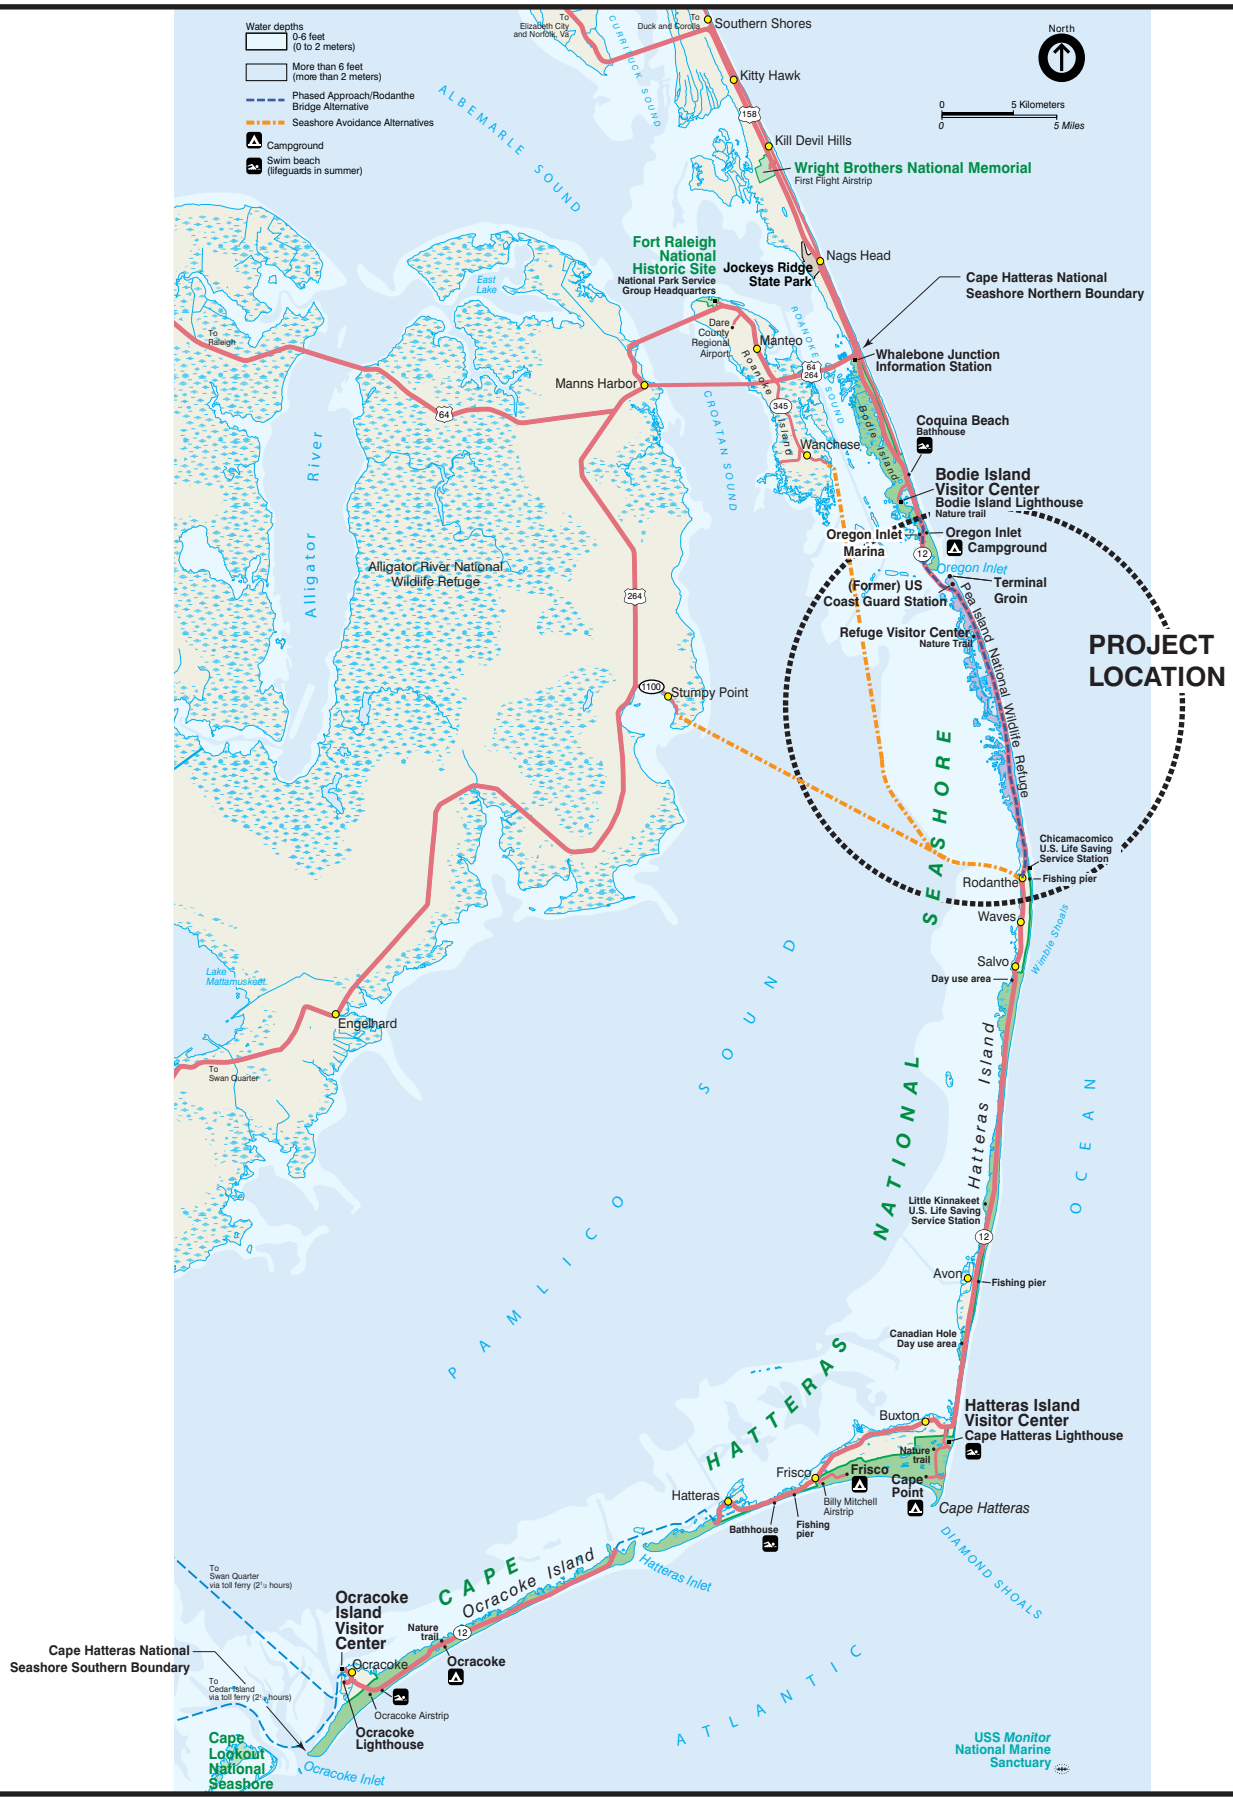
2. The action includes all possible planning, as defined in 23 CFR 774.17, to minimize harm to the property resulting from such use.

If the analysis of this section concludes that there is no feasible and prudent avoidance alternative, then the USDOT may approve only the alternative that causes the least overall harm in light of the statute's preservation purpose.

All five of the Parallel Bridge Corridor alternatives, including the Phased Approach/Rodanthe Bridge Alternative (Preferred), as well as the two Pamlico Sound Bridge Corridor alternatives would require land from the Cape Hatteras National Seashore (the Seashore) on Bodie Island at the northern end of the project area. The Seashore is a Section 4(f) property. The Parallel Bridge Corridor with Nourishment Alternative and the Phased Approach/Rodanthe Nourishment Alternative also would use land to varying degrees from the Pea Island National Wildlife Refuge (the Refuge) for beach nourishment. The Refuge, part of the Seashore, also qualifies as a Section 4(f) property given its function as a refuge and its eligibility for the National Register of Historic Places (NRHP). It also serves as a public park and recreational area. The Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives also would use land from both the Refuge and the Rodanthe Historic District. The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) would only use land from the Seashore. None of the alternatives would utilize land from the historic (former) Oregon Inlet US Coast Guard Station located on the northern end of Hatteras Island (see the discussion in Section 5.2 and the figures in that section).

This evaluation documents the location and characteristics of Section 4(f) properties in the project area, describes the impacts of the detailed study alternatives to the Section 4(f) properties, discusses why no prudent and feasible avoidance alternatives were identified, discusses the alternatives with regard to the least overall harm determination, discusses why there would be no constructive use of Section 4(f) resources, addresses the measures taken to minimize harm, and describes coordination with officials having jurisdiction over all Section 4(f) properties. The following evaluation was performed in compliance with the new Section 4(f) regulations (23 CFR 774) which became effective April 11, 2008.

5.1 Description of Section 4(f) Properties



5.1.1 Cape Hatteras National Seashore

The Cape Hatteras National Seashore (the Seashore) in Dare and Hyde counties stretches north to south across three islands: Bodie, Hatteras, and Ocracoke (see Figure 5-1). These barrier islands have a wealth of sand dunes (natural and man-made), marshes, and woodlands. The creation of the Seashore was authorized by Congress in 1937; 21 years later the final parcels were acquired and the Seashore was dedicated. The Seashore has contributed to the area's increase in tourism. It was the first in a series of national seashores established to preserve significant segments of unspoiled barrier islands along the Atlantic and Gulf coasts for the benefit and enjoyment of the people. The Seashore contains 30,319 acres (12,270 hectares) of land and 70 miles (113 kilometers) of open, virtually unspoiled beach. The State of North Carolina donated approximately 10,000 acres (4,047 hectares) of the Seashore's land.

The Seashore is a publicly owned park and recreation area that is owned by the federal government and administered by the National Park Service (NPS). At the south end of Bodie Island, the Seashore boundary follows the mean low water mark along the Atlantic Ocean side. On the Pamlico Sound side, the boundary follows the shoreline until it reaches Oregon Inlet. The Seashore boundary on Hatteras Island, between Oregon Inlet and Rodanthe, extends to the mean low water mark along the ocean-side and extends 150 feet (45.7 meters) from the shoreline into Pamlico Sound on the west side. Figure 5-3 in Section 5.2.1 shows the Seashore boundary in the vicinity of Oregon Inlet. The boundary does not follow the shoreline in the Oregon Inlet area and on southern Bodie Island because it was based on the shoreline location in the 1950s. The NPS and the US Fish and Wildlife Service (USFWS) share management duties where the boundaries of the Seashore overlap with those of the Pea Island National Wildlife Refuge (the Refuge) at the northern end of Hatteras Island. Within the Refuge, the NPS is responsible for visitors and visitor facilities, while the USFWS is responsible for wildlife management.

Eight villages exist within the Seashore's authorized boundaries (seven on Hatteras Island). These villages are neither parklands nor a part of the Refuge and therefore are not protected under Section 4(f). Only one village, Rodanthe, exists within the project area. The villages, the Seashore, and the Refuge are served by NC 12, a hard-surfaced, two-lane road approximately 50 miles (80 kilometers) in length bisecting the Seashore. By act of Congress, the section of the Seashore encompassing the Refuge was to include a road. This road, which connects Rodanthe to Oregon Inlet, was completed in 1953 and was connected to Bodie Island to the north by Bonner Bridge in 1963. The NPS contributed a substantial amount of the funds ($500,000) to construct Bonner Bridge, which was considered a benefit to the Seashore at that time. The roadway, including the bridge, was officially designated as NC 12 in 1963; it is maintained by the North Carolina Department of Transportation (NCDOT) under agreements with the US Department of Interior (DOI). NC 12 is the only road providing motor vehicle traffic through the Seashore. Vehicle access between Bodie Island and Hatteras Island is provided by Bonner Bridge across the Oregon Inlet. The easement for NC 12 is 100 feet (30.5 meters) wide and it is not considered to be a Section 4(f) property.

Access to Ocracoke Island is provided by the Hatteras Inlet ferry between Hatteras Island and Ocracoke Island, as well as by two NCDOT ferry routes operating between Ocracoke Island and the mainland. Ocracoke Island is outside the project area and thus not discussed in detail.

CAPE HATTERAS NATIONAL SEASHORE

Figure 5-1

5.1.1.1 Facilities

Seashore facilities administered by the NPS on Bodie Island are:

- Whalebone Junction Information Station;
- Bookstore;
- Coquina Beach Day Use Facility;
- Bodie Island Visitor Center and Nature Trail;
- Bodie Island Lighthouse;
- Oregon Inlet Campground*; and
- Oregon Inlet Marina and Fishing Center*.

Seashore facilities on Hatteras Island (including those within the Refuge) are:

- Refuge Visitor Center, wildlife trails, and boat ramp*;
- Rodanthe fishing pier;
- Little Kinnakeet US Life Saving Service Station;
- Avon fishing pier;
- Hatteras Island Visitor Center and Nature Trail;
- Cape Hatteras Lighthouse;
- Cape Point Campground and Day Use Facilities;
- Frisco Campground; and
- Frisco area fishing pier.

* Facilities marked with an asterisk (*) are in the project area.

Photographs of several of these facilities are shown in Figure 5-2. The Atlantic Ocean beach south of Whalebone Junction is completely within the Seashore and is open for public use beginning about 5 miles (8 kilometers) south of Whalebone Junction (see Figure 5-1). The Oregon Inlet Marina and Fishing Center, and the Oregon Inlet Campground are the only Seashore facilities near the Parallel Bridge Corridor alternatives (including the Preferred Alternative), the Pamlico Sound Bridge Corridor alternatives, and the Bonner Bridge (see Figure 5-2 and Figure 5-3 in Section 5.2.1). An unpaved beach access road intersects with NC 12 near the Oregon Inlet Marina and Fishing Center. Although not owned or maintained by the NPS, but rather by the NCDOT, catwalks used by fishermen are attached to Bonner Bridge off Hatteras Island. There also are catwalks on the Bodie Island side, but they are now over land and unusable for fishing. A parking lot and a path to the catwalks immediately south of Bonner Bridge are maintained by

1. Oregon Inlet Marina and Fishing Center at Seashore

2. (Former) US Coast Guard Station

3. North Pond in Refuge

4. Refuge Visitor Center

5. North Pond Wildlife Trail in Refuge

6. Refuge Boat Ramp

8. Other Buildings at Chicamacomico Life Saving Station

SECTION 4(f) PROPERTIES AND FEATURES

Figure 5-2

the NPS. The Refuge Visitor Center and its associated parking lot, the North Pond Wildlife Trail, and the boat ramp are all located near the Parallel Bridge Corridor alternatives (including the Preferred Alternative) (see also Section 3.5.2, as well as Figure 5-4 in Section 5.2.2).

5.1.1.2 Activities

Visitors to the Seashore enjoy a wide variety of recreational opportunities related to the unique natural, undeveloped, and protected character of the area. The recreational activities on the Seashore lands within the project area include:

- Camping at Oregon Inlet Campground on Bodie Island;
- Ocean fishing excursions from the Oregon Inlet Marina and Fishing Center;
- Surf fishing off Atlantic Ocean beaches;
- Fishing from the catwalks on the south end of Bonner Bridge (owned and maintained by NCDOT);
- Surfing in the Atlantic Ocean;
- Wind-boarding (windsurfing) and kite surfing in Pamlico Sound;
- Walking along the beach;
- Birding and hiking on wildlife trails in the Refuge;
- Visiting the Refuge Visitor Center;
- Cycling along NC 12;
- Fishing from the Rodanthe fishing pier; and
- Driving the "Outer Banks Scenic Byway," which includes NC 12 from Whalebone Junction south through the Seashore.

5.1.1.3 Plans

The *General Management Plan and Amended Environmental Assessment for Cape Hatteras National Seashore* (NPS, 1984) and the *Draft Revised Statement for Management* (NPS, 1991) serve as the NPS plans for the Seashore. These plans are described in Section 3.1.3.3.

5.1.2 Pea Island National Wildlife Refuge

The Pea Island National Wildlife Refuge (the Refuge), located within the Seashore, is a Section 4(f) property. In addition, it also is a significant publicly owned recreation area and a significant historic site eligible for inclusion on the NRHP.

The Refuge was established in 1938 by President Franklin Roosevelt through Executive Order 7864. The Refuge was created in recognition of the importance of the area for wildlife. Executive Order 7864 reserved the area for migratory birds and other wildlife to advance the

purposes of the Migratory Bird Conservation Act of 1929. The Refuge was named for the once-abundant dune peas in the area that attracted waterfowl. The Refuge was developed by Civilian Conservation Corps (CCC) projects in the 1930s. The Refuge is owned by the federal government and administered by the USFWS.

The primary purpose of the Refuge is to serve as a refuge and breeding ground for migratory birds and other wildlife. Refuge objectives are to:

- "Provide nesting, resting, and wintering habitat for migratory birds, including the greater snow geese and other migratory waterfowl, shorebirds, wading birds, raptors, and neotropical migrants.

- Provide habitat and protection for endangered and threatened species.

- Provide opportunities for public enjoyment of wildlife and wildlands resources. Public use programs focus on interpretation, environmental education, wildlife observation, wildlife photography, and fishing." (Pea Island National Wildlife Refuge web site, August 18, 2008.)

Executive Order 7864 also established a boundary for the Refuge, which extends to the mean high tide level on both sides of Hatteras Island. The northern boundary of the Refuge extends to Oregon Inlet and the southern boundary is immediately adjacent to private properties in Rodanthe (see Figure 3-1a through Figure 3-1c in Section 3.1.2). The Refuge contains 5,834 acres (2,361 hectares) of land. Proclamation Boundary Waters also were established in 1938 around the Refuge but are not a part of the Refuge. This is an area that extends into Pamlico Sound to protect migratory birds from hunters in areas adjacent to the Refuge. The Proclamation Boundary Waters cover approximately 25,700 acres (10,400 hectares) of Pamlico Sound. The USFWS Refuge has a Memorandum of Agreement (MOA) with the NPS to manage the parking lots and comfort station on Hatteras Island. The USFWS is responsible for the natural resources management within the Refuge.

The Refuge is comprised of ocean beach, dunes, upland, fresh and brackish water ponds, salt flats, and salt marsh (see Figure E-2 in Appendix E). Its bird list boasts more than 365 species; its wildlife list has 25 species of mammals, 24 species of reptiles, and five species of amphibians. Concentrations of ducks, geese, swans, wading birds, shore birds, raptors, and neotropical migrants are seasonally abundant in the Refuge. The Refuge has 1,000 acres (404.7 hectares) of manageable waterfowl impoundments. Several shorebird nesting areas and wading bird rookeries are on the Refuge. Endangered and threatened species include peregrine falcons, loggerhead sea turtles, and piping plovers (Pea Island National Wildlife Refuge web site, August 18, 2008).

The Refuge was also found to be eligible for the NRHP. It is eligible under Criterion A of the National Historic Preservation Act of 1966, as amended, in the areas of conservation and social history. The Refuge is an outstanding example of the national wildlife refuges that were created during the early twentieth century. With its manmade dikes and dunes, the Refuge also illustrates the efforts of the CCC on the Outer Banks to protect and revitalize natural resources. The US Congress established the CCC in 1933 during the Great Depression to employ young men in the conservation and development of natural resources. The original dunes constructed by the CCC no longer exist because of natural processes; however, they have been artificially maintained by NCDOT to protect the road and are still considered by the North Carolina State Historic Preservation Officer (SHPO) to be representative of the activities of the CCC. The original dikes still exist but have been altered over time. The eligibility determination was made by the

NCDOT and affirmed by the SHPO. A letter dated September 17, 2003 from the SHPO that affirms the above finding is contained in Appendix A.

Like for the Seashore, NC 12 provides the primary access to and through the Refuge. NC 12 runs the full length of the Refuge south to north, as decreed by Act of Congress. The length of NC 12 (south to north) within the Refuge between Rodanthe and Oregon Inlet is approximately 11.8 miles (19.0 kilometers). The width of the Refuge ranges from 0.25 mile (0.4 kilometer) to 1 mile (1.6 kilometers) from east to west (see Figure 5-4a and Figure 5-4b in Section 5.2.2).

5.1.2.1 Facilities

Facilities within the Refuge are:

- Salt Flats and North Pond Wildlife Trails*;
- Refuge Visitor Center*;
- Fishing catwalks at Oregon Inlet;
- A boat ramp;
- Seven parking lots; and
- Headquarters buildings*.

*Facilities marked with an asterisk (*) are managed by the USFWS.

Several of these facilities are illustrated in Figure 5-2 and their locations are shown in Figure 5-4a and Figure 5-4b in Section 5.2.2. The beach is open to the public.

5.1.2.2 Visitors and Their Activities

Based on traffic counts, the Refuge receives 2.7 million visitors annually (Pea Island National Wildlife Refuge web site, August 18, 2008). Most vehicles, however, only pass through the Refuge to and from other destinations on Hatteras Island. Refuge management estimated the number of visitors with the Refuge as a destination to be about 420,000 persons in 2003 and 540,000 persons in 2004. The peak-season for visitors to the Refuge is June through October. During the summer peak-season, many families visit the Refuge to participate in typical beach activities. The peak-season for birding is in the fall, but it is also popular in the spring and winter. The peak-season for fishing is also in the fall. All activities in the Refuge during the winter are weather dependent; on many cold and windy days, there is little activity in the Refuge, but nice winter days can be relatively active. Weekends are not necessarily the busiest times in the Refuge because many locals use the Refuge during the week to conduct their activities, including participating in Refuge sponsored programs during the week (Friday is the busiest day for Refuge programs). In particular, retirees and birders visit the Refuge during the week. "Wings over Water" is a program put on by the Refuge staff for birders and other wildlife enthusiasts each fall. It is a large program that visitors come to the Outer Banks specifically to participate in, as opposed to many of the Refuge's other programs that people tend to find out about and participate in while visiting the Outer Banks for other reasons.

5.1.2.3 Administrative and Management Law

The National Wildlife Refuge System Administration Act of 1966 created and provides for the administration and management of the National Wildlife Refuge System (NWRS). This system includes wildlife refuges, areas for the protection and conservation of fish and wildlife threatened with extinction, wildlife ranges, game ranges, wildlife management areas, and waterfowl production areas.

The National Wildlife Refuge System Improvement Act of 1997 amends and builds upon the 1966 act to ensure that the NWRS is managed as a national system of related lands, waters, and interests for the protection and conservation of our nation's wildlife resources. The 1997 Act further defines the mission of the NWRS as to "administer a national network of lands and waters for the conservation, management, and where appropriate, restoration of the fish, wildlife and plant resources and their habitats within the United States for the benefit of present and future generations of Americans." The 1997 Act also requires the US Secretary of the Interior to ensure the biological integrity, diversity, and environmental health of the NWRS is maintained, and it defines compatible wildlife-dependent recreation as "legitimate and appropriate general public use of the System." It establishes hunting, fishing, wildlife observation and photography, and environmental education and interpretation as "priority public uses" where compatible with the mission and purpose of individual national wildlife refuges. The 1997 Act also retained the refuge managers' authority to use sound professional judgment in determining compatible public uses on national wildlife refuges and whether or not they will be allowed, and established a formal process for determining "compatible use." Proposed uses must be concurrently evaluated for compatibility with refuge goals, objectives, and the refuge's establishing legislation. This evaluation, known as a Compatibility Determination, also requires public notice and comment. However, the 1997 Act was not intended "to in any way change, restrict, or eliminate" existing road right-of-ways within refuges.

The USFWS manages the Pea Island National Wildlife Refuge. As a first priority, federal law and regulation require the Refuge manager to ensure that all uses of the Refuge are compatible with Executive Order 7864 and the National Wildlife Refuge System Improvement Act of 1997, and that any allowed use of the Refuge be compatible with the mission ("wildlife first") and purpose of the Refuge.

5.1.2.4 Plan

The USFWS prepared a *Comprehensive Conservation Plan* (USFWS, 2006) to guide the management of the Refuge. The plan, which was published in September 2006, outlines programs and corresponding resource needs for the proceeding 15 years, as mandated by the National Wildlife Refuge System Improvement Act of 1997. The purpose of the plan is to identify the role that the Refuge will play in support of the mission of the National Wildlife Refuge System and to provide long-term guidance to the Refuge's management programs and activities. The plan is further described in Section 3.1.3.4.

5.1.3 (Former) Oregon Inlet US Coast Guard Station

The (former) Oregon Inlet US Coast Guard Station at the northern end of Hatteras Island is listed in the NRHP under Criterion A for maritime and social history and Criterion C for architecture. Built in 1898, the station was part of a 19th century initiative to establish life saving stations along the length of the Outer Banks. Small settlements for the life saving crews and their families

grew up around the stations. The Oregon Inlet Station—as it was constructed in 1898—was similar, but not identical, to other stations built along the Outer Banks during that period.

The US Coast Guard no longer uses the structure and does not plan to return to it. The State of North Carolina owns the building, and the North Carolina Aquarium Society (part of the North Carolina Department of Environment and Natural Resources [NCDENR]) oversees its operations and maintenance. The structure today is surrounded by sand on three sides and is in deteriorating condition. The North Carolina Aquarium Society let a project for bidding in July 2008 to stabilize the structure, remove the modern dormitory attached to the building, and restore the exterior. The objective of this contract would be to stabilize the structure until final decisions are made regarding the Bonner Bridge replacement project. If the terminal groin were removed, much of the northern end of Hatteras Island in the vicinity of Oregon Inlet, including the site of the (former) Oregon Inlet US Coast Guard Station, would be threatened by island erosion and likely would be lost to that erosion (see Section 3.6.3.5 for a discussion of the short- and long-term impacts of the removal of the terminal groin on Oregon Inlet and the northern end of Hatteras Island).

5.1.4 Rodanthe Historic District and Chicamacomico Life Saving Station

5.1.4.1 Rodanthe Historic District

The Rodanthe Historic District is eligible for the NRHP under Criterion A for social history. The string of early twentieth century houses originally built by early fisherman and merchants, the Chicamacomico Life Saving Station at Rodanthe, and the fish house on Rodanthe harbor, are rare illustrations of life in the pre-tourism age of the mid- to late-twentieth century. The metamorphosis of Dare County from an area of small, largely isolated, fishing villages to a tourist destination of international renown has almost completely eliminated any vestige of life on the Outer Banks before the late-twentieth century. The Rodanthe Historic District is also eligible under Criterion C for architecture. The contributing elements in the historic district have maintained its architectural integrity commensurate with the original setting of the village. The Rodanthe Historic District was found eligible by the NCDOT and affirmed by the SHPO (see Section 3.4.1.3 for additional information).

The boundaries for this small NRHP-eligible historic district encompass the greatest concentration of substantially intact historic resources in Rodanthe (see Figure 5-5 in Section 5.2.4). The Rodanthe Historic District encompasses approximately 17.1 acres (6.9 hectares). The following six buildings and associated resources were included in the district: the Levene W. (or Levine) Midgett House; the J. Frank Meekins Fish House; the (former) Rodanthe School (non-contributing); the Chicamacomico Life Saving Station; the Cornelius P. Midgett (or Payne) House, on its new site minus its boathouse and cemetery; and the John Allen Midgett House. The components of the district generally line the east and west sides of NC 12, in the Myrna Peters Road and Midgett Drive area. Descriptions of the contributing resources are in Section 3.4.1.3.

5.1.4.2 Chicamacomico Life Saving Station

The Chicamacomico Life Saving Station is illustrative of a property type unique to the Outer Banks (see Figure 5-2). Listed on the NRHP in 1976, Chicamacomico is the most complete of any of the life saving stations built along the North Carolina barrier islands. In addition to its original 1874 board-and batten station and 1911 shingle-style facility, Chicamacomico contains a detached frame kitchen, cisterns, a flag tower, and several frame boathouses, all of which are well-preserved. Surrounding the life saving station are several houses, including the Cornelius P.

Midgett House. The Chicamacomico Life Saving Station site illustrates both the persistence of traditional local architecture and the introduction of nationally popular architectural designs during the early-twentieth century in Dare County.

The Chicamacomico Life Saving Station is owned by the Chicamacomico Historical Association. The station is operated as a museum. It is open from mid-April through November, though the operational months may be extended in the near future. Future plans for the station include: restoration of the 1874 station house; construction of a museum building to house the growing collections; continued research; expansion of the programming, living history displays, and physical facilities; and creation of two separate historic interpretive areas on-site.

5.2 Use of Section 4(f) Properties

There are three types of use: permanent, temporary, and constructive. A Section 4(f) property "use" is defined in regulations (23 CFR 774.17) as:

1. When land is permanently incorporated into a transportation facility;

2. When there is a temporary occupancy of land that is adverse in terms of the statute's preservation purpose as determined by the criteria within 23 CFR 774.13(d); or

3. When there is a constructive use of Section 4(f) property as determined by the criteria within 23 CFR 774.15.

All project alternatives were reviewed to determine if they included one or more of these types of use. All of the Parallel Bridge Corridor alternatives, as well as the Pamlico Sound Bridge Corridor alternatives, include the permanent incorporation of Seashore land at the site of the new bridge over Oregon Inlet. All of the replacement bridge corridor alternatives, except for the Phased Approach/Rodanthe Bridge Alternative (Preferred) and the Pamlico Sound Bridge Corridor alternatives, would include additional uses of Section 4(f) properties. There are no adverse temporary uses of Section 4(f) properties with any of the alternatives; construction activities would occur within existing or acquired right-of-way/easement. Also, it was determined that there is not a constructive use of any Section 4(f) properties with the Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) (see Section 5.5 for additional discussion of constructive use). Additional discussion on the use of Section 4(f) properties follows.

5.2.1 Cape Hatteras National Seashore on Bodie Island

5.2.1.1 Parallel Bridge Corridor Alternatives – Including the Phased Approach/Rodanthe Bridge Alternative (Preferred)

The Parallel Bridge Corridor alternatives include five different alternatives:

1. Nourishment;

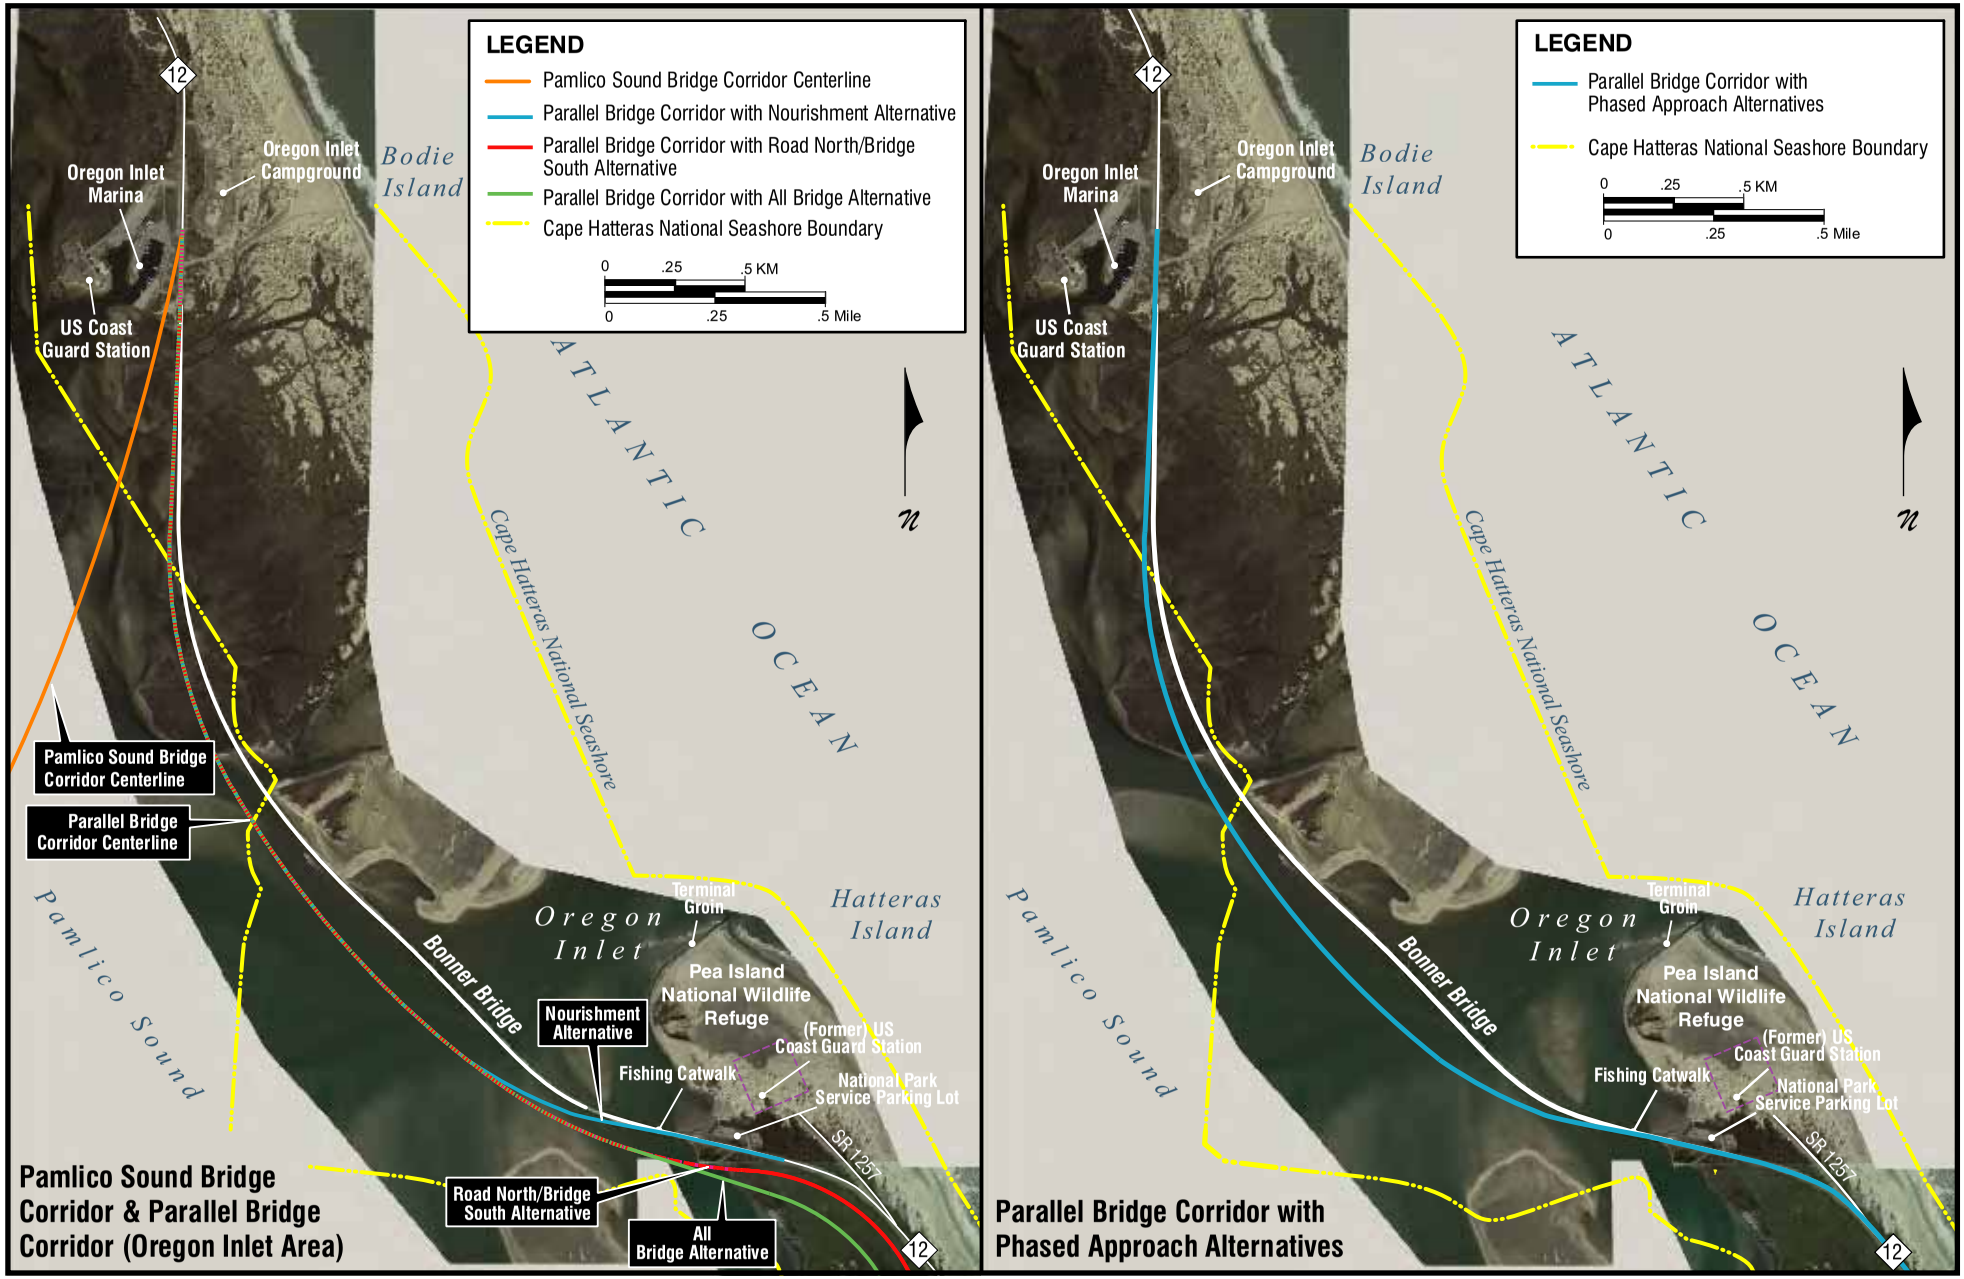
2. Road North/Bridge South;

3. All Bridge;

4. Phased Approach/Rodanthe Bridge (Preferred); and

5. Phased Approach/Rodanthe Nourishment.

These alternatives are shown in relation to the Seashore on Bodie Island in Figure 5-3.



All of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would require the permanent use of land from the Cape Hatteras National Seashore (the Seashore) on Bodie Island, adjacent to Oregon Inlet. Figure 5-3 shows the Parallel Bridge Corridor alternatives (including the Preferred Alternative). All Parallel Bridge Corridor alternatives would use approximately 6.3 acres (2.6 hectares) of Seashore land at the northern terminus of the proposed project on Bodie Island. It is the same 6.3 acres (2.6 hectares) for all of the Parallel Bridge Corridor alternatives. No Seashore land would be used on Hatteras Island (except in the area of the Seashore that also includes the Refuge, which is discussed in Section 5.2.2) or on Ocracoke Island under any of the Parallel Bridge Corridor alternatives.

On Bodie Island, the Bonner Bridge and NC 12 occupy approximately the same amount of land as would be used by any of the Parallel Bridge Corridor alternatives (including the Preferred Alternative). This land would be returned to the Seashore after the bridge is demolished and removed. Thus, the permanent use of approximately 6.3 acres (2.6 hectares) of the Seashore on Bodie Island under any of the Parallel Bridge Corridor alternatives is approximately equal to the 6.3 acres (2.6 hectares) of existing Seashore land that would be returned to the Seashore upon demolition of the existing bridge, resulting in no net gain or loss of Seashore lands by any of the Parallel Bridge Corridor alternatives.

As seen in Figure 5-3, the Oregon Inlet Marina and Fishing Center and the Oregon Inlet Campground are Seashore facilities within the replacement bridge project area on Bodie Island. The existing intersection between NC 12 and the Oregon Inlet Marina and Fishing Center driveway would be retained. As described in Section 4.5.1, with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) NC 12 would be relocated slightly west of its existing location in the vicinity of the driveways to the Oregon Inlet Marina and the Oregon Inlet Campground, but the driveways themselves would not be relocated and access to these facilities would not be affected. There is a septic system leach field used by the Oregon Inlet Marina adjacent to the west side of NC 12 to the south of the Oregon Inlet Marina driveway. The exact location of this leach field is not known, but if it is determined during final design that the proposed project would impact the leach field, it would be moved to an appropriate adjacent location so that Oregon Inlet Marina operations would not be affected. Access to all Seashore facilities on Bodie Island would be retained; additional discussion is in Section 4.5.3.

No substantial changes in views from the Seashore and its activities would occur (see Section 4.3.3). The Parallel Bridge Corridor alternatives (including the Preferred Alternative) would be approximately 26 feet (7.9 meters) to 62 feet (18.9 meters) closer to the Oregon Inlet Marina than the Bonner Bridge, with the lower distance being at the Marina entrance. The change increases to the 62 feet (18.9 meters) as the project proceeds south. Thus, the scale of the proposed project in relation to the marina would be slightly greater than that of Bonner Bridge.

Charter fishing boats operating out of the Seashore's Oregon Inlet Marina and Fishing Center follow an unmarked natural channel known as Bridge to Old House Channel (or known more commonly as the "crack") to reach the navigation span of Bonner Bridge instead of the Oregon Inlet Channel/Old House Channel maintained by the US Army Corps of Engineers (USACE). (Figure 3-7 shows the location of channels in the Oregon Inlet area.) On a peak day,

USE OF AND RELATIONSHIP TO SECTION 4(f) PROPERTIES NEAR OREGON INLET

Figure 5-3

approximately 130 charter vessels travel via "the crack." Following "the crack" shortens the distance traveled by vessels operating between the fishing center and the Bonner Bridge's navigation span from approximately 5 miles (8 kilometers) to about 2.5 miles (4.0 kilometers). As illustrated in Figure 3-7, the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would cross "the crack" as the bridge moves south across Oregon Inlet. Since charter fishing boats require as much as 30 feet (9 meters) of clearance, the proposed project would block these vessels from traveling along "the crack" and increase the time it takes for these vessels to travel from the fishing center to the ocean since they would need to follow the Oregon Inlet Channel/Old House Channel maintained by the USACE. The travel time to the ocean from the fishing center would be approximately 30 minutes longer via Oregon Inlet Channel/Old House Channel than via "the crack" according to Marina management. Crossing "the crack" with the Parallel Bridge Corridor alternatives (including the Preferred Alternative) cannot be avoided because "the crack" runs adjacent to and parallel to Bonner Bridge for part of its length. This increased travel time does not constitute a use of a Section 4(f) property, but it does represent an impact on people who travel by boat between the Marina and Oregon Inlet.

Carbon monoxide (CO) levels exceeding the National Ambient Air Quality Standards (NAAQS) would not be generated by the any of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) (see Section 4.9 for further discussion of air quality impacts).

The noise level and abatement analysis for the Parallel Bridge Corridor alternatives (including the Preferred Alternative) is discussed in Section 4.10 and indicates that Federal Highway Administration (FHWA) Noise Abatement Criteria (NAC) would not be exceeded at sensitive receptors in the Seashore on Bodie Island (see also Figure 4-2 and Table 4-31). The analysis also indicates that there would not be a substantial increase in noise levels at these receptors. Therefore, no traffic noise abatement would be needed at park facilities.

No new facilities or activities are planned by the NPS near the Bodie Island end of the Parallel Bridge Corridor alternatives (including the Preferred Alternative).

5.2.1.2 Pamlico Sound Bridge Corridor Alternatives

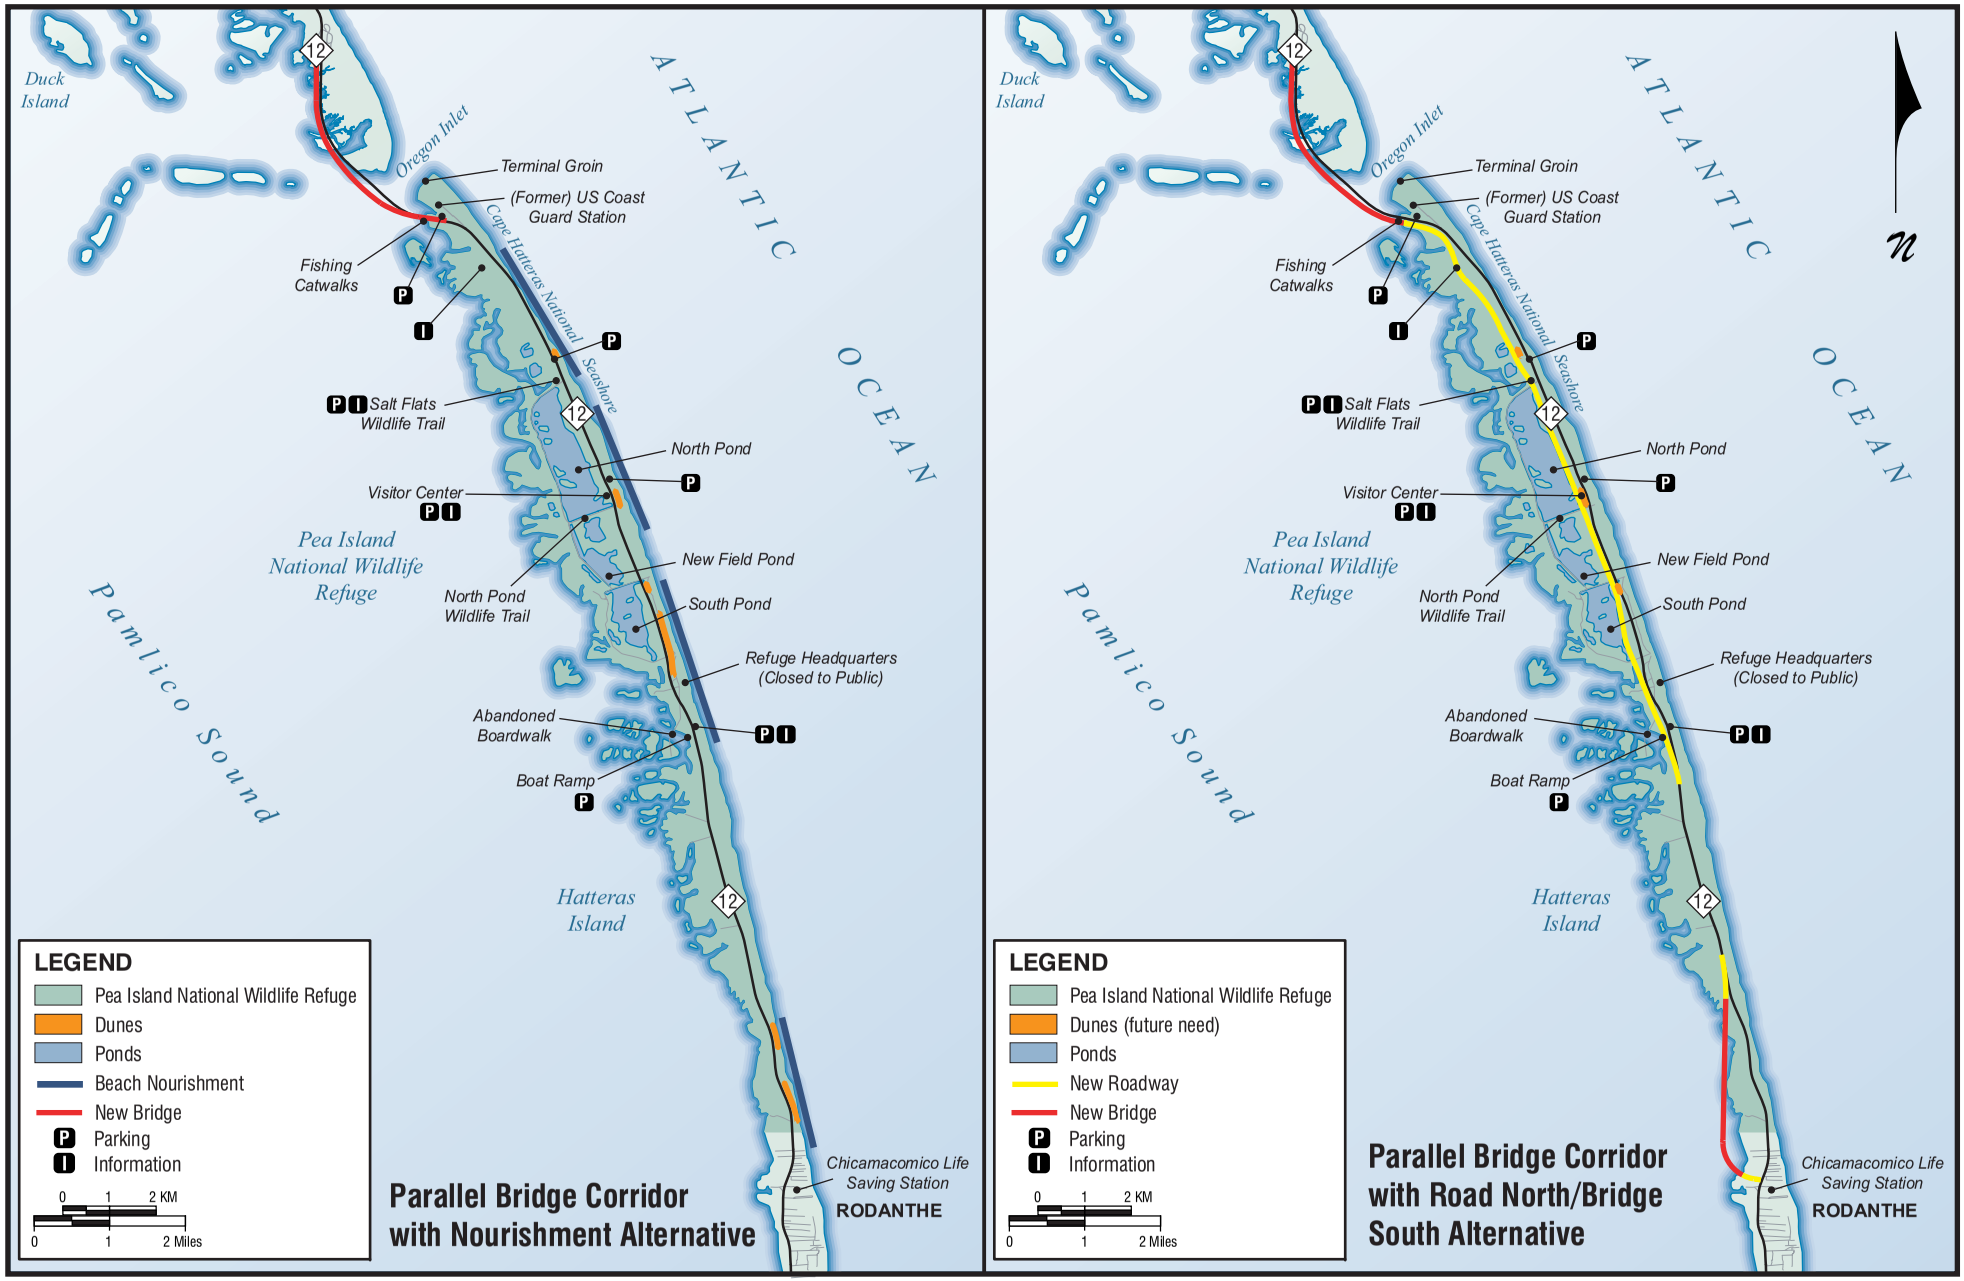
The Pamlico Sound Bridge Corridor alternatives (see Figure 5-3) would use approximately 7.3 acres (3.0 hectares) of the Seashore on Bodie Island. Like the Parallel Bridge Corridor alternatives, the approximately 6.3 acres (2.6 hectares) of the Seashore currently in use by the Bonner Bridge, would be returned to the Seashore upon the construction of the new bridge and the demolition of the old. This would result in a net use of 1.0 acre (0.4 hectare) of the Seashore lands on Bodie Island.

Other than a larger permanent use of Seashore properties, the impacts to Seashore facilities are similar to those discussed for the Parallel Bridge Corridor alternatives above, and there would be no substantial impact because of noise or carbon monoxide. A replacement bridge in the Pamlico Sound would be visible for a greater distance than Bonner Bridge given its longer length and height; however, it would appear as a thin line on the horizon as it would be located several miles to the west. Access to Seashore facilities would be retained.

No new facilities or activities are planned by the NPS near the Bodie Island end of the Seashore within the project area for the Pamlico Sound Bridge Corridor alternatives.

5.2.2 Pea Island National Wildlife Refuge/Cape Hatteras National Seashore on Hatteras Island

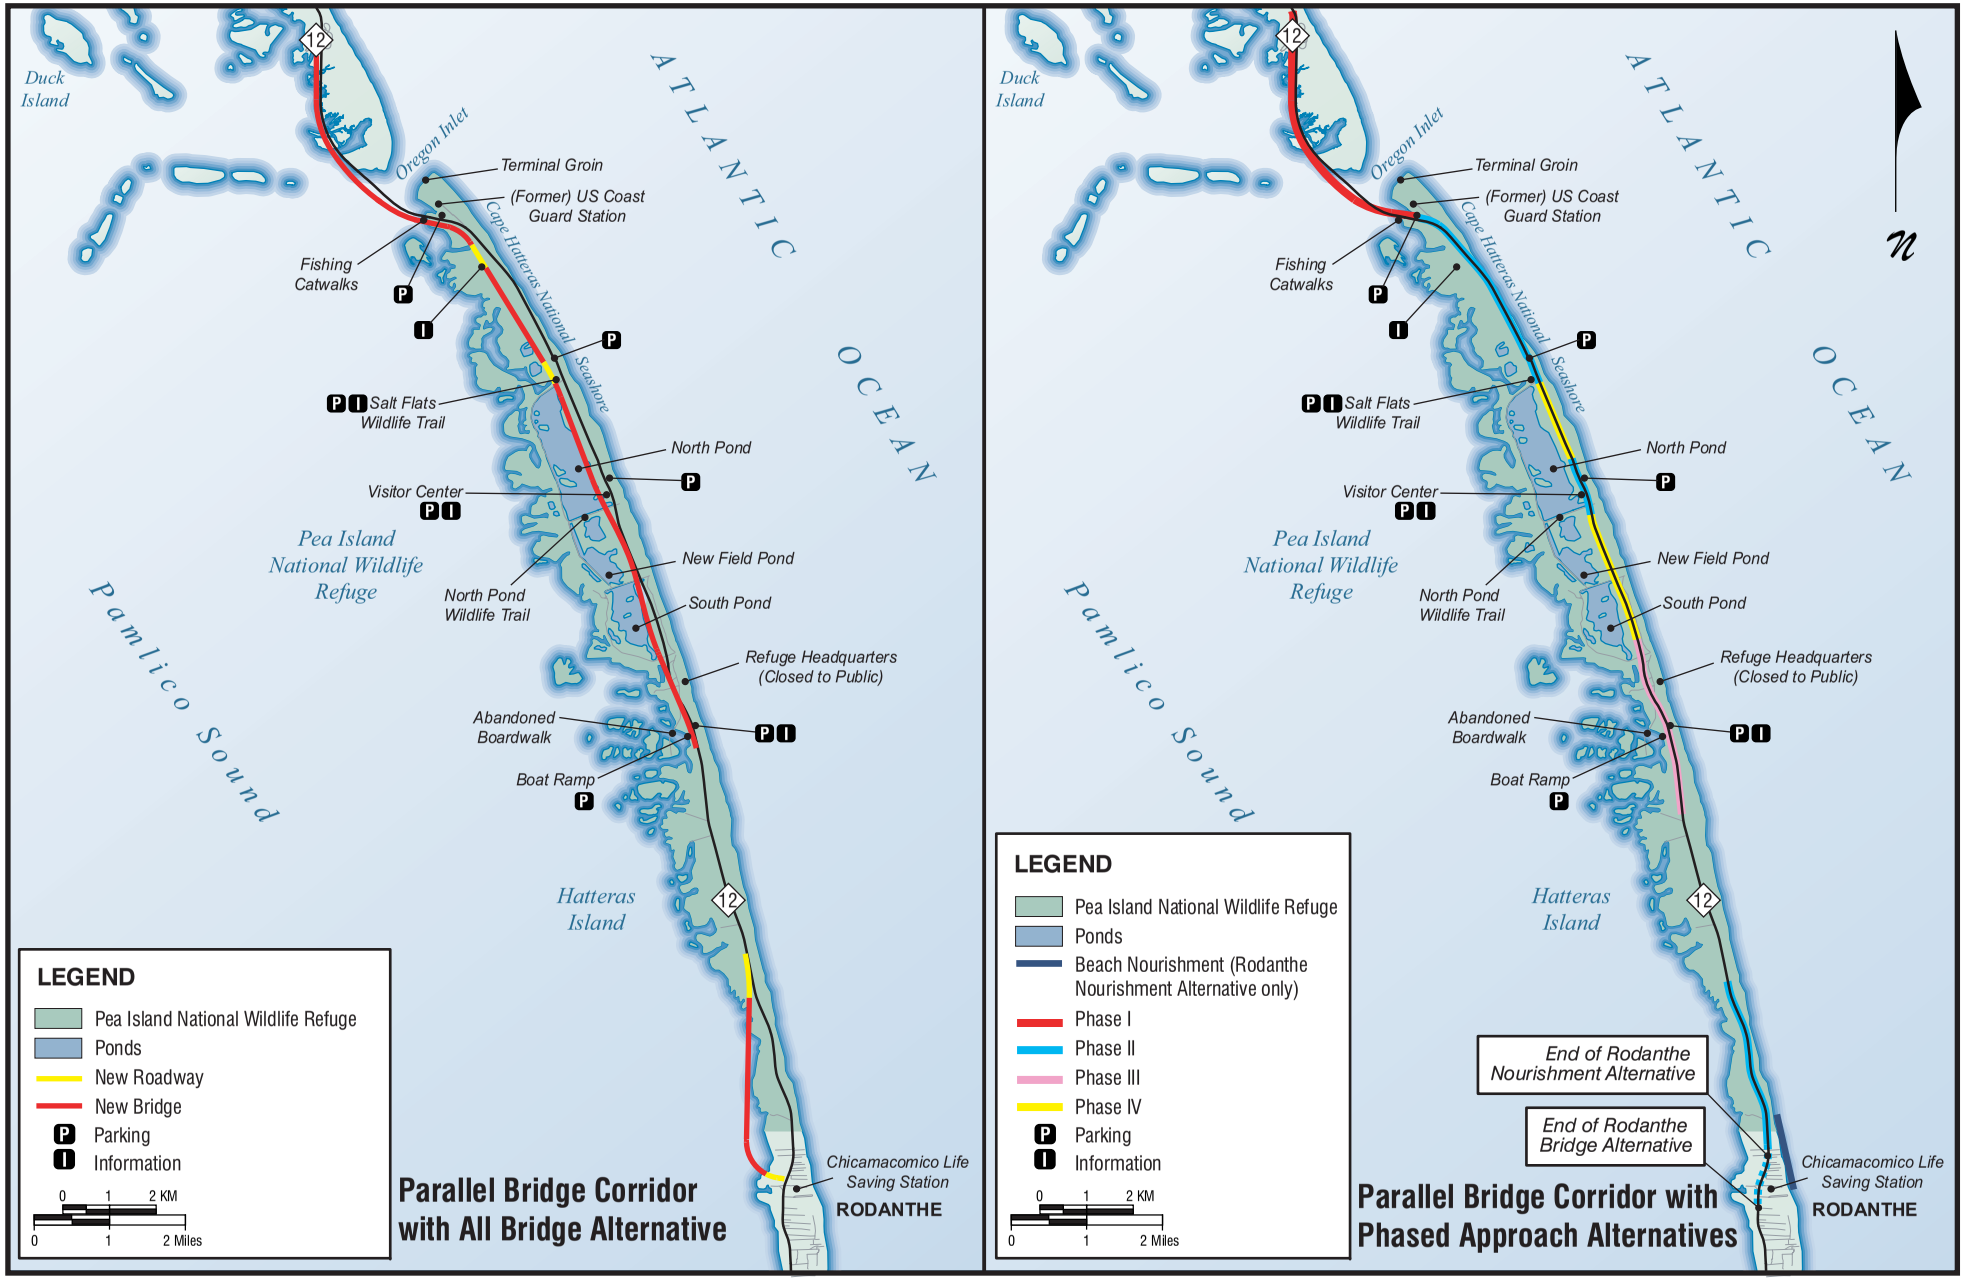
5.2.2.1 Parallel Bridge Corridor Alternatives – Including the Phased Approach/Rodanthe Bridge Alternative (Preferred)



All of the Parallel Bridge Corridor alternatives, except for the Phased Approach/Rodanthe Bridge Alternative (Preferred), would have different uses of property from the Pea Island National Wildlife Refuge (the Refuge) on Hatteras Island. As discussed earlier, the Refuge is also part of the Cape Hatteras National Seashore (the Seashore).

With the Nourishment Alternative, 19.7 acres (8.0 hectares) of Section 4(f) property associated with newly constructed dunes, plus nourishment of 6.3 miles (10.1 kilometers) of the Seashore within the Refuge would be required (see Figure 5-4a). A new access road to the Oregon Inlet area parking lot would require an additional 0.2 acre (0.07 hectare) of new right-of-way. NC 12 would remain in its existing easement. The Nourishment Alternative would have No Adverse Effect on the refuge as a historic resource, because the new dunes would be on the east side of NC 12 and the existing dikes and ponds would remain (see Section 4.4.1.2). Given that dunes are already present within the Refuge, the addition of new dunes would not represent a visual intrusion.

The Road North/Bridge South Alternative would require the use of 90.3 acres (36.6 hectares) of Section 4(f) property to establish a new 100-foot (30.5-meter) wide right-of-way to relocate NC 12 as a roadway and as a bridge (see Figure 5-4a). Approximately 2,961 feet (903 meters) of new bridge would be built over the Refuge. This alternative would also require a new access road to the Oregon Inlet parking area and 0.2 acre (0.07 hectare) of right-of-way would be needed, similar to the Nourishment Alternative. An additional 2.9 acres (1.2 hectares) also would be required for the construction of three new dunes. The Road North/Bridge South Alternative would have an Adverse Effect on the Refuge as a historic resource because the relocation of NC 12 would intrude up to 700 feet (213 meters) into the existing dikes and ponds (see Section 4.4.1.2). No long distance views would be blocked or altered. Vegetation that was disturbed with the construction of the new road would be restored upon completion. The long-term visual impact of this alternative would be minimal as it is similar to the natural changes in the current landscape resulting from beach erosion and ocean overwash.



The All Bridge Alternative would require the use of 89.6 acres (36.2 hectares) of Section 4(f) property to establish a new 100-foot (30.5-meter) wide right-of-way that would be used for the relocated NC 12 and new bridge (see Figure 5-4b). Approximately 7.6 miles (12.2 kilometers) of bridge would be built within the Refuge. A new access road to the Oregon Inlet area parking lot would necessitate 2.6 acres (1.1 hectares) of new right-of-way. The All Bridge Alternative would also have an Adverse Effect on the Refuge as a historic resource because the elevation of NC 12 on a bridge would place NC 12 over the existing dikes and ponds. The bridge would present a contrast with the natural character of the Refuge. The bridge would dominate views from the dunes lining the beach and, as the dunes disappear over time, it would also dominate views from the beach. It would also dominate views from the wildlife trails along the Refuge's ponds, interrupting the undeveloped and protected character of the Refuge that makes it rare along the eastern US seaboard in terms of views and a setting for recreation activities.

The visual impacts of both of the Phased Approach alternatives (including the Preferred Alternative) are described in Section 4.3.2. The Phased Approach alternatives (including the Preferred Alternative) would introduce a sizable new linear man-made feature for approximately 10 miles (16.1 kilometers) through the Refuge. NC 12 through most of the Refuge would be elevated on a bridge within the existing easement.

USE OF AND RELATIONSHIP TO SECTION 4(f) PROPERTIES

Figure 5-4a

USE OF AND RELATIONSHIP TO 4(f) PROPERTIES

Figure 5-4b

The bridge would be at an elevation of approximately 33.5 feet (10.2 meters) above mean sea level (approximately 30 feet [9.1 meters] above ground), allowing for the bottom of the superstructure to be a minimum of 25 feet (7.6 meters) above mean high water (see Figure 2-24). This is 15 feet (4.6 meters) higher than the height assumed for the All Bridge Alternative. Like the All Bridge Alternative, the bridge would present a contrast with the natural character of the Refuge. The bridge would dominate views from the dunes lining the beach and, as the dunes disappear over time, it also would dominate views of the beach and ultimately the ocean. It would not be characteristic of the undeveloped and protected character of the Refuge that makes it rare along the eastern US seaboard in terms of views and a setting for recreation activities.

The Phased Approach/Rodanthe Nourishment Alternative would use 1,500 feet (457.2 meters) of beach within the Refuge for beach nourishment activities (see Figure 5-4b). This alternative would also have an Adverse Effect on the Refuge as a historic resource because of the elevation of NC 12 on bridges as it passes through the historic Refuge landscape.

The Phased Approach/Rodanthe Bridge Alternative (Preferred) would not require the use of any property from the Refuge because it would be constructed and maintained entirely within the NCDOT's existing NC 12 easement (see Figure 5-4b). While the Phased Approach/Rodanthe Bridge Alternative (Preferred) would have an Adverse Effect on the Refuge as a historic resource because of the introduction of bridges as it passes through the historic Refuge landscape, the protected activities, features, and attributes of the Refuge would not be substantially impaired, and thus there would not be a constructive use of the Refuge (also see Section 5.5). All of the Parallel Bridge Corridor alternatives, except for the Phased Approach/Rodanthe Bridge Alternative (Preferred), would result in a permanent use of Refuge lands outside of the existing easement.

As described in Section 4.1.4.2, all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would maintain road access to the Refuge and its beaches. Section 4.5.3.1 provides specific discussion related to accessibility of Refuge facilities by the Parallel Bridge Corridor alternatives. The Nourishment Alternative would change the location of access to the fishing parking lot near Oregon Inlet; all other recreational facilities would remain accessible. Refuge access would be maintained in an altered format with the Parallel Bridge Corridor with Road North/Bridge South Alternative. Trail and beach access would be altered as NC 12 would be moved westward in the northern part of the Refuge, and the Rodanthe area bridge would bypass the southern 1.6 miles (2.6 kilometers) of the Refuge land near Rodanthe. The All Bridge Alternative would reduce Refuge access so that there would be only three locations to access Refuge facilities from NC 12. Access would be provided at the northern end of the Refuge near the catwalks parking lot, at the entrance to the Salt Flats Wildlife Trail to the north of the ponds, and south of the ponds. The All Bridge Alternative also would bypass the Refuge Visitor Center, the North Pond Trail, the Refuge headquarters, and the boat ramp. When completed, the bridges associated with both of the Phased Approach alternatives (including the Preferred Alternative) would limit access to the Refuge and to the beach to two locations off of NC 12; one access point would be at the catwalks parking lot at the northern end of the Refuge via access ramps constructed during Phases I and II. The second access point would be within the stable area south of the ponds. The two Phased Approach alternatives (including the Preferred Alternative) would bypass the Refuge Visitor Center, two trails, the Refuge headquarters, and the boat ramp. Access to the ocean and to the beach would be limited to the two access points. Figure 5-4a and Figure 5-4b show the Refuge access points for each of the alternatives.

CO levels exceeding the NAAQS would not be generated by the any of the Parallel Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

The noise level and abatement analysis for the Parallel Bridge Corridor alternatives is discussed in Section 4.10 and indicates that FHWA NAC would not be exceeded in the Refuge (see also Figure 4-2 and Table 4-31). Therefore, no traffic noise abatement would be needed at Refuge facilities.

No new facilities or activities are planned by the USFWS on the Hatteras Island side of the Parallel Bridge Corridor alternatives.

5.2.2.2 Pamlico Sound Bridge Corridor Alternatives

The Pamlico Sound Bridge Corridor alternatives would require no use of the Refuge, as they are not within the Refuge boundaries. In addition, the Pamlico Sound Bridge Corridor alternatives would have No Adverse Effect on the Refuge as a historic resource. The Pamlico Sound Bridge Corridor is not within the Refuge and is far enough from the Refuge to have no adverse visual effect.

The Pamlico Sound Bridge Corridor alternatives would eliminate access via a paved road to and from the Refuge, as NC 12 through the Refuge would not be maintained upon the completion of the Pamlico Sound Bridge. However, the USFWS and NPS would likely continue to provide some type of access to the Seashore and the Refuge for recreational users. Section 4.5.3.1 provides specific discussion relating to accessibility of Refuge facilities by the Pamlico Sound Bridge Corridor alternatives. While the loss of NC 12 would inconvenience Refuge visitors, the USFWS' view is that the primary purpose of the Refuge is not for recreation but to serve as a breeding ground and refuge for migratory birds and other wildlife, and that adequate access can be provided without a paved road.

CO levels exceeding the NAAQS would not be generated by the any of the Pamlico Sound Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

The noise level and abatement analysis for the Pamlico Sound Bridge Corridor alternatives is discussed in Section 4.10 and indicates that FHWA NAC would not be exceeded (see also Figure 4-2 and Table 4-31). The Pamlico Sound Bridge Corridor alternatives would reduce noise levels in the Refuge.

5.2.3 (Former) Oregon Inlet US Coast Guard Station

5.2.3.1 Parallel Bridge Corridor Alternatives – Including the Phased Approach/Rodanthe Bridge Alternative (Preferred)

None of the Parallel Bridge Corridor alternatives (including the Preferred Alternative), or the Pamlico Sound Bridge Corridor alternatives, would require any use of property from the (former) Oregon Inlet US Coast Guard Station, located on Hatteras Island within the Refuge (see Figure 5-3). However, all of the Parallel Bridge Corridor alternatives would have an Adverse Effect on the (former) Oregon Inlet US Coast Guard Station because of the greater height of the new Oregon Inlet Bridge (33.5 to 70 feet [10.2 to 21.3 meters] compared to the Bonner Bridge up to 15 feet [11.1 meters]). The visual impacts from the Parallel Bridge Corridor alternatives would alter the historic view, function, and setting of the station.

A replacement bridge in the Parallel Bridge Corridor would retain NC 12 through the Refuge and terminate at the southern tip of Bodie Island. The Parallel Bridge corridor could allow for the relocation of the (former) Oregon Inlet US Coast Guard Station across Oregon Inlet by bridge or

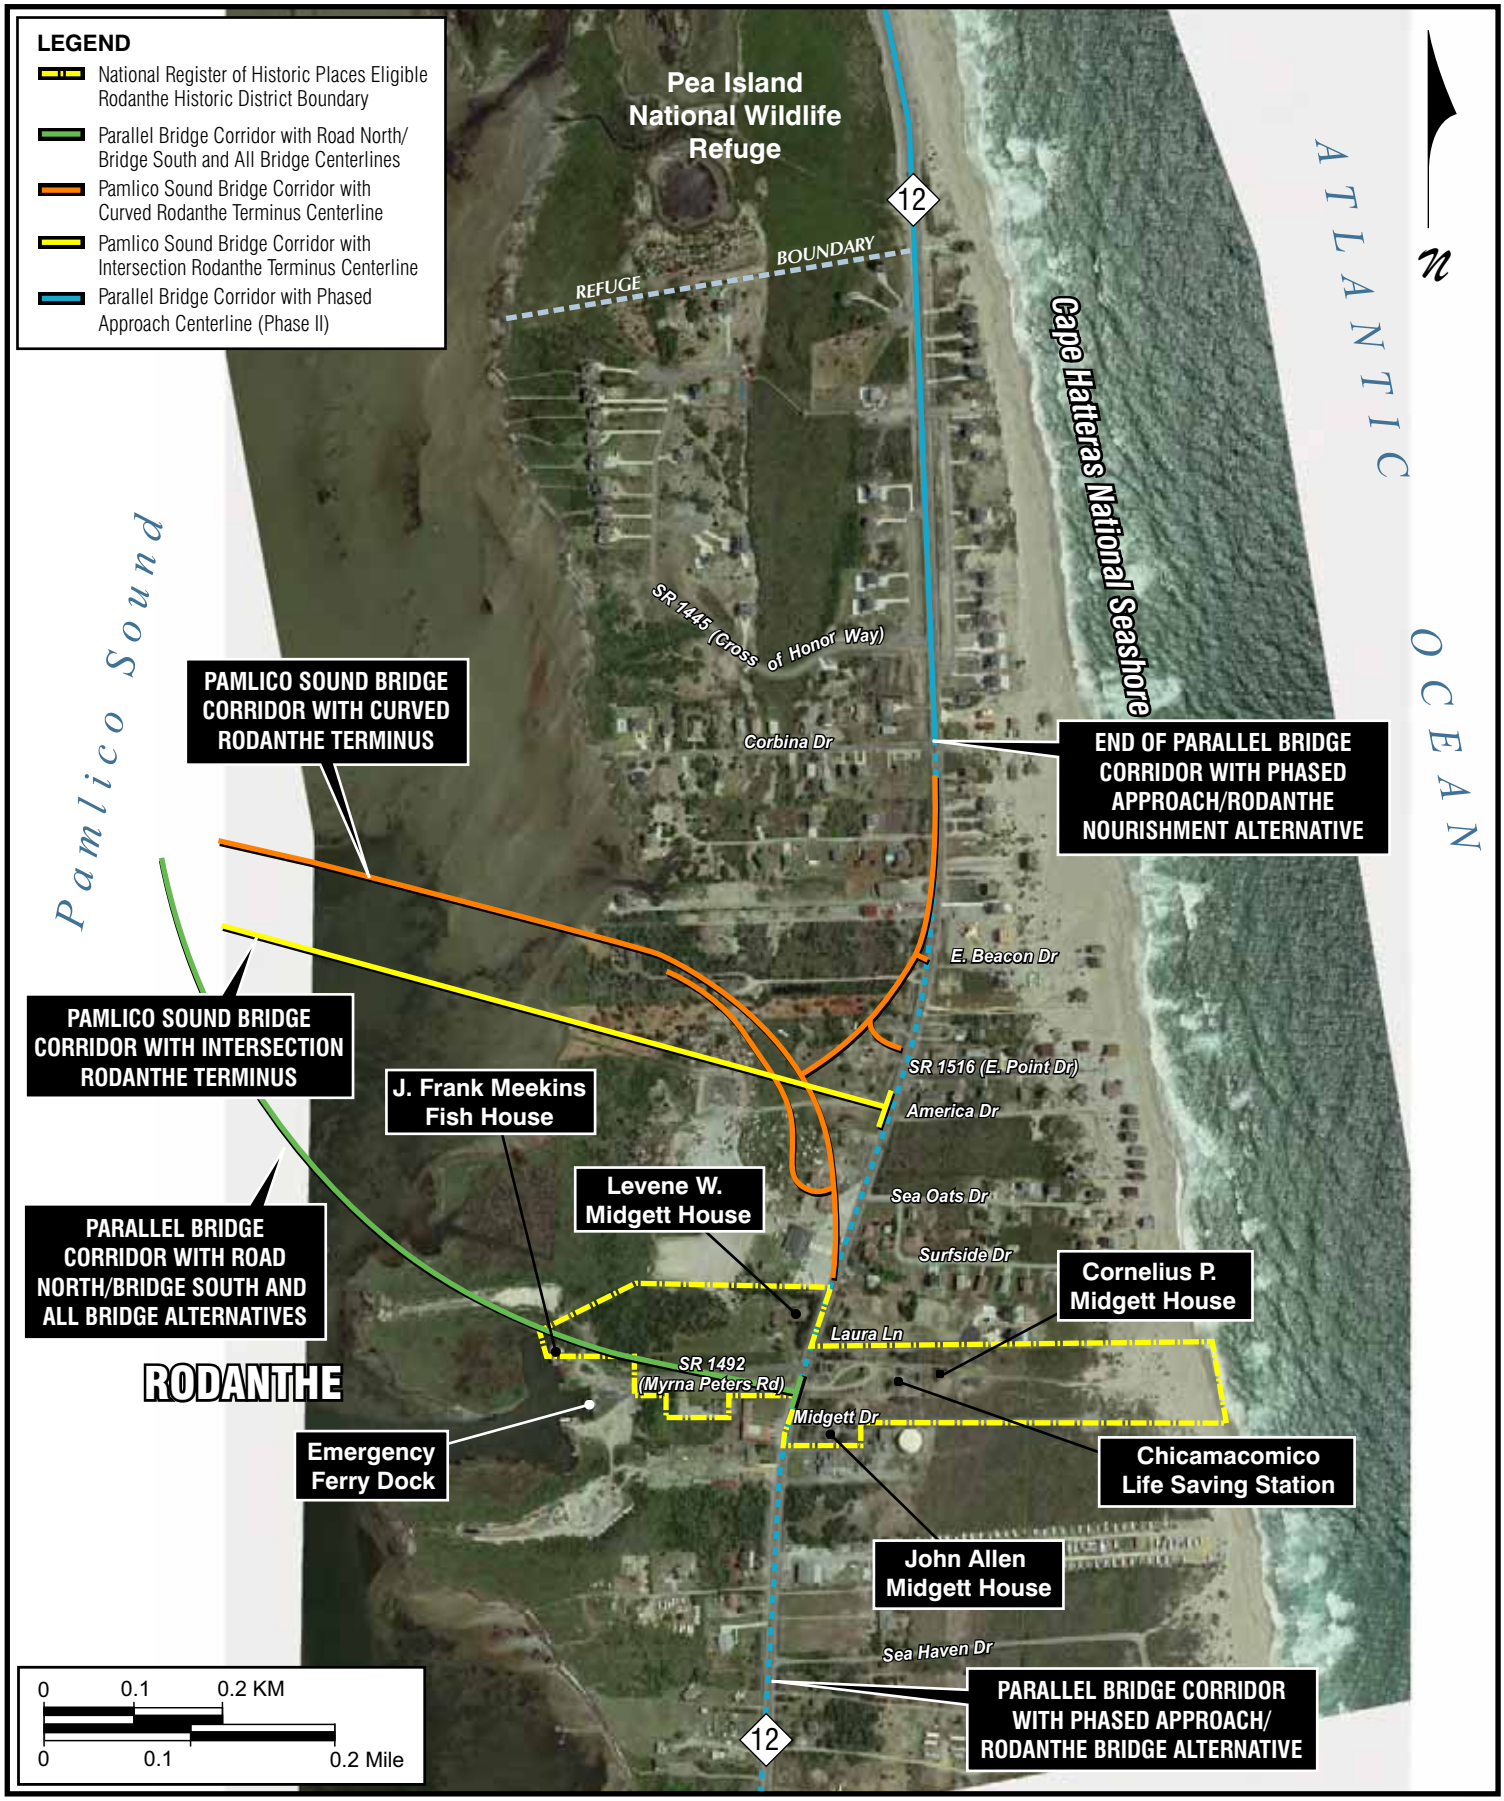
by barge as discussed in Section 4.4.1.2 under "(Former) Oregon Inlet US Coast Guard Station." The retention of the terminal groin, required by all of the Parallel Bridge Corridor alternatives, would allow the station to remain on its current site, if desired by its owners. If it remains at its current site, road access to the (former) Oregon Inlet US Coast Guard Station would remain with all of the Parallel Bridge Corridor alternatives.

CO levels exceeding the NAAQS would not be generated by the any of the Parallel Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

More specific detail as to the impacts of each of the Parallel Bridge Corridor alternatives on the (former) Oregon Inlet US Coast Guard Station is included in Section 4.4.1.2.

5.2.3.2 Pamlico Sound Bridge Corridor Alternatives

The Pamlico Sound Bridge Corridor alternatives would not require any use of the (former) Oregon Inlet US Coast Guard Station on Hatteras Island. However, these alternatives would have an Adverse Effect on the property because of the potential for loss of access to the facility and the potential for the removal of the terminal groin at the northern end of Hatteras Island upon completion of the proposed project. If the groin is removed, the northern end of Hatteras Island would continue its southward migration (see Section 3.6.2.5) and, unless relocated, the (former) Oregon Inlet US Coast Guard Station would be washed away. For more discussion of the terminal groin, see Section 4.6.3.



If the Pamlico Sound Bridge Corridor alternatives were selected for implementation, the Refuge and the Seashore plan to conduct an access study. The NCDOT would seek and accept an invitation to participate in the development of alternate access plans if one of the Pamlico Sound Bridge Corridor alternatives were selected for construction and it would suggest that the SHPO be invited to participate. If the alternate access provided is found by the SHPO to contribute potentially to the further neglect of the (former) Oregon Inlet US Coast Guard Station, the NCDOT would help ensure this potential impact is adequately mitigated. Such mitigation would not include retaining NC 12 in the Refuge. If mitigation would include relocating the (former) Oregon Inlet US Coast Guard Station to a site north of Oregon Inlet, the NCDOT currently expects not to demolish Bonner Bridge until that relocation occurred or until a process for taking the building across Oregon Inlet on a barge is developed. However, given the current condition of Bonner Bridge, consideration would have to be given to whether or not the weight of the (former) Oregon Inlet US Coast Guard Station could be safely borne by Bonner Bridge before relocation across the bridge could take place.

CO levels exceeding the NAAQS would not be generated by the any of the Pamlico Sound Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

5.2.4 Rodanthe Historic District – Including Chicamacomico Life Saving Station

5.2.4.1 Parallel Bridge Corridor Alternatives – Including the Phased Approach/Rodanthe Bridge Alternative (Preferred)

As shown in Figure 5-5, there would be no use of the Rodanthe Historic District (the historic district) or the Chicamacomico Life Saving Station with the Parallel Bridge Corridor with Phased Approach alternatives (including the Preferred Alternative) and the Parallel Bridge Corridor with

USE OF AND RELATIONSHIP TO SECTION 4(f) PROPERTIES IN RODANTHE

Figure 5-5

Nourishment Alternative, as these alternatives would remain within the existing NC 12 right-of-way within the historic district.

There would be no use of the historic district or the Chicamacomico Life Saving Station as a result of the Nourishment Alternative because no component of the alternative would be in proximity to these resources. The Nourishment Alternative would involve nourishment to protect NC 12 north of Chicamacomico and the historic district. No dunes would be built in proximity to Chicamacomico or the historic district. The alternative would have No Effect on these historic resources.

The Road North/Bridge South and All Bridge alternatives would be identical in the vicinity of the Chicamacomico Life Saving Station and other historic district features (see Figure 5-5). The alternatives would have an Adverse Effect on the Chicamacomico Life Saving Station and the historic district, as they would both pass through the district. These alternatives would approach Rodanthe on a bridge approximately 28 feet (8.5 meters) high through Pamlico Sound, and would enter the historic district at an elevation of approximately 18 feet (5.5 meters). Bridge foundations probably would be built every 100 feet (30.5 meters). The bridge component would end and the final fill leading down to an intersection at NC 12 would begin within the historic district. The alternatives would terminate at NC 12 across from the existing NC 12/Midgett Drive intersection, just to the south of the Chicamacomico Life Saving Station. The Road North/Bridge South and All Bridge alternatives would both use land from non-contributing properties within the historic district, and would pass 14 feet (4.3 meters) and 320 feet (97.5 meters), respectively, from two contributing structures – the J. Frank Meekins Fish House and Levene W. Midgett House. These alternatives would be visible from the watchtower that is a part of the Chicamacomico Life Saving Station building.

At one house within the historic district peak-hour noise levels in 2025 would approach or exceed FHWA's NAC with the Nourishment Alternative and with the two Phased Approach alternatives. Myrna Peters Road would be separated from NC 12 with the Road North/Bridge South and All Bridge alternatives, so an alternative access road to NC 12 immediately south of the (former) Rodanthe School would be provided to the J. Frank Meekins Fish House and the (former) Rodanthe School because their current access to NC 12 is via Myrna Peters Road. The Chicamacomico Life Saving Station would not leave control of its owners.

The Phased Approach/Rodanthe Bridge Alternative (Preferred) would involve building a bridge in the existing right-of-way with a one-lane/one-way frontage road on either side of the bridge substructure at grade to maintain access to adjoining properties (see Figure 5-5). These features would fit into the existing right-of-way in the historic district, but would use the entire right-of-way width. NC 12 would remain on bridge until a point on NC 12 is reached that is 230 feet (70.1 meters) from the 2060 high erosion shoreline. Because this point occurs south of the historic district, the bridge would pass through the historic district. The bridge would be at its full height of 33.5 feet (10.2 meters) above mean high sea level (approximately 30 feet [9.1 meters] above ground) as it enters the historic district from the north (see Figure 2-24). It would begin to drop down to grade within the historic district and would be approximately 12.5 feet (4.0 meters) above ground at the southernmost point of the district. It would still be 30 feet (9.1 meters) above ground in front of the Chicamacomico Life Saving Station. Direct vehicle access across the right-of-way would be eliminated in the historic district. Connections between the frontage roads would be approximately 963 feet (294.0 meters) south of the southern district boundary and 734 feet (224.0 meters) north of the northern district boundary. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would have an Adverse Effect on the Chicamacomico Life Saving Station and the historic district because of the change in the visual setting. The bridge would be a

feature not in keeping with the historic setting of the structures contained within the district in terms of its height and structural components, and it would impede views across NC 12; however, the elevated structure would allow travelers to see more of the landscape.

CO levels exceeding the NAAQS would not be generated by the any of the Parallel Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

Like the Parallel Bridge Corridor with Nourishment Alternative, the Phased Approach/Rodanthe Nourishment Alternative would maintain NC 12 in Rodanthe using beach nourishment, so it would have No Effect on the Life Saving Station or the historic district.

5.2.4.2 Pamlico Sound Bridge Corridor Alternatives

The two Pamlico Sound Bridge Corridor Alternatives would not require any use of lands in the historic district or the Chicamacomico Life Saving Station (see Figure 5-5). The proposed bridge within the Pamlico Sound Bridge Corridor would be visible from the watchtower that is a part of the Life Saving Station building. However, the viewshed currently is occupied by modern commercial and residential development and an automobile junkyard (partially removed between 2003 and 2004). Thus, the integrity of the view has already been compromised.

At one house within the historic district peak-hour noise levels in 2025 would approach or exceed FHWA's NAC with the Pamlico Sound Bridge Corridor. However, this noise level is associated more with the forecast growth in traffic than the implementation of a bridge within the Pamlico Sound Bridge Corridor. There would be no difference at the affected site between 2025 noise levels assuming Bonner Bridge remains in place and 2025 noise levels with the Pamlico Sound Bridge Corridor. In addition, 2025 noise levels with the Pamlico Sound Bridge Corridor would only be 2 dBA above existing conditions, an imperceptible difference. Since the Pamlico Sound Bridge Corridor ends north of the eligible district, the proposed bridge would not affect traffic volumes that pass through the historic district on NC 12. Because of the lack of direct or substantial indirect affects on the historic district, there is no reason to believe that a bridge in the Pamlico Sound Bridge Corridor would lead to neglect of the properties within the district.

CO levels exceeding the NAAQS would not be generated by the any of the Pamlico Sound Bridge Corridor alternatives (see Section 4.9 for further discussion of air quality impacts).

Given these findings, the Pamlico Sound Bridge Corridor has No Adverse Effect on the Chicamacomico Life Saving Station and the associated historic district as historic resources.

5.3 Avoidance Alternatives

FHWA cannot approve the use of a Section 4(f) property if there is a feasible and prudent avoidance alternative available. A feasible and prudent avoidance alternative is one that avoids using Section 4(f) property and does not cause other severe problems of a magnitude that substantially outweighs the importance of protecting the Section 4(f) property. Few avoidance alternatives exist for this project because of its location along the narrow barrier islands that largely consist of lands protected by Section 4(f). The rehabilitation of the Bonner Bridge is the only alternative presented in Chapter 2 that would completely avoid the use of lands from the Seashore. This section considers whether the rehabilitation of Bonner Bridge, as well as two other potential avoidance options, are feasible and prudent. The second avoidance option would involve building a bridge across the Pamlico Sound from Rodanthe, the northernmost location of

privately held land on Hatteras Island south of Oregon Inlet, to Wanchese on Roanoke Island. The third avoidance option would involve building a new Oregon Inlet bridge completely within the existing NC 12 right-of-way within the Seashore at the southern end of Bodie Island and over Oregon Inlet (see Figure 5-3).

The No-Action Alternative, which calls for the construction of a small-scale ferry service, is not an avoidance alternative because ferry facilities would have to be constructed within the Seashore and within either the Refuge or Rodanthe to provide service between Bodie and Hatteras islands. Access to the mainland also would remain via existing ferry routes from the mainland (i.e., Cedar Island and Swan Quarter) to Ocracoke Island and then the existing ferry route from Ocracoke Island to Hatteras Island. This route offers space for approximately 400 to 450 vehicle crossings per day during the summer. Emergency ferry service across Oregon Inlet was provided from November 1990 to February 1991 after Bonner Bridge had been damaged by a dredge and was closed. This emergency ferry service had a maximum transport of 900 vehicles per day and took 80 minutes, including loading and unloading. A similar service would not meet the existing demand or the 2025 average daily traffic of 9,600 vehicles per day and peak traffic of 25,200 vehicles per day (see Table 1-2 in Section 1.5.6). This alternative also would not avoid the use of land from Section 4(f) property.

5.3.1 Rehabilitate Bonner Bridge Avoidance Alternative

As discussed in Section 1.3.3, Bonner Bridge has recurring maintenance problems, insufficient ship impact strength, and a narrow navigation zone. Bonner Bridge has required continual maintenance since its construction.

Three major continuing maintenance problems exist:

- Deterioration of the bridge through extensive corrosion of the reinforcing steel and major spalling of concrete on the supporting structures;
- Scour to a depth equal to or greater than the critical depth for the piles supporting the substructure; and
- Natural channel migration that results in the periodic need for boat traffic to pass beneath a span adjacent to, and lower than, the bridge's primary navigation span.

Although these problems have been addressed in previous rehabilitation programs (and in a rehabilitation project currently underway), they continue to occur. Extensive maintenance and repair expenditures are expected to continue on a regular basis, and the required repairs are expected to grow in expense and complexity. The replacement of complete bridge piers and complete girders could eventually be needed, requiring closure of Bonner Bridge for months at a time. Thus, a rehabilitation alternative that dealt with bridge deterioration and scour would be an ongoing effort disruptive to traffic operations on the bridge, and not a one-time project to extend the life of Bonner Bridge for many years.

With continued rehabilitation, the narrow navigation span zone of Bonner Bridge would remain, and the potential benefits of reduced dredging associated with the proposed project would not occur. Navigation heights and widths cannot be changed without replacing those spans.

Finally, Bonner Bridge was not designed to withstand the impact of a dredge, a vessel type that regularly operates near the bridge. A hopper dredge demolished several spans of Bonner Bridge in late 1990, requiring the bridge to be closed from October 1990 to February 1991. Nothing short of replacing the substructure with the type proposed for either of the replacement bridge corridors (see Section 2.10.1.2) would provide the strength needed. The existing substructure is too short and too light to withstand the required ship impact loads.

The rehabilitation of the Bonner Bridge presents unacceptable safety, maintenance, and operational problems for the traveling public. This alternative would also fail to meet the purpose and need for the project as it would not include long-term maintenance and protection to NC 12 south of Oregon Inlet which is frequently threatened by shoreline erosion and overwash.

The severe problems described above outweigh the importance of protecting the 30,319 acre (12,270 hectare) Seashore from the use of the 6.3 to 7.3 acres (2.6 to 3.0 hectares) that would be required to complete the project with one of the other alternatives under consideration. Therefore, the Rehabilitate Bonner Bridge Avoidance Alternative is determined to not be a feasible and prudent avoidance alternative because the problems identified above cumulatively cause unique problems and impacts of extraordinary magnitude.

5.3.2 Bridge from Rodanthe to Roanoke Island Avoidance Alternative

A bridge from Rodanthe to either Roanoke Island (near Wanchese) or the mainland (at Stumpy Point) would avoid the use of Seashore lands. However, only the Roanoke Island terminus of this alternative would avoid using Section 4(f) property. The mainland terminus is not an avoidance alternative because it would require using land from the Alligator River National Wildlife Refuge, a Section 4(f) property. The Alligator River National Wildlife Refuge could not be avoided because US 264, the road leading to Stumpy Point, passes through the Alligator River National Wildlife Refuge (see Figure 5-1) and would need to be improved to adequately serve NC 12 traffic.

With the western bridge termini at Roanoke Island, existing roads would need to be improved in order to accommodate NC 12 traffic. Shifting traffic from one road to another often necessitates road improvements, such as wider lanes and shallower curves, to safely accommodate the increased traffic volumes. In order to add NC 12 traffic to Wanchese, such improvements would be needed on NC 345. Widening NC 345 would reduce the distance to adjacent development through Wanchese from 15 feet (4.6 meters) to approximately 6 feet (1.8 meters). The introduction of traffic, the loss of front yards, and the displacement of several homes would substantially reduce the quality of life of this rural community. In addition, the cohesion of the community would be reduced since the introduction of NC 12 traffic would make it more difficult to cross NC 345 to visit neighbors. Constructing a bypass around Wanchese would require construction on new location through estuarine wetlands (forested and marsh) for almost 2 miles (3.2 kilometers).

Further, the alternative of building a new bridge from Rodanthe to Roanoke Island would not meet the project's purpose and need, which calls for a "new means of access from Bodie Island to Hatteras Island." With the alternative of building a new bridge from Rodanthe to Roanoke Island, the internal traffic circulation patterns of the Outer Banks would be altered. The travel distance from Whalebone to Rodanthe for users of the Seashore would increase by 29 percent (from 24 miles [38.6 kilometers] to 31 miles [49.9 kilometers]). Road user costs would increase with distance, and travelers would no longer be able to go directly from Bodie Island to Hatteras

and Ocracoke islands. Response times for emergency service vehicles also would be increased by this alternative. Because the sole hospital serving the area is on Bodie Island, the loss of a direct connection to Bodie Island from Hatteras and Ocracoke islands would be a severe impact on residents and visitors.

The connection of electric and utility services to Hatteras Island also would need to be relocated from the southern end of Bodie Island (northern terminus of Bonner Bridge) to Roanoke Island at a northern terminus for a replacement bridge from Roanoke Island to Rodanthe. The major components of such a relocation would be moving the electrical substation now on Bodie Island to Roanoke Island, placing telephone lines on 22 miles (35.4 kilometers) of new bridge, and placing electric lines adjacent to 22 miles (35.4 kilometers) of new bridge. In contrast, a bridge in the Pamlico Sound Bridge Corridor would be 17.5 miles (28.2 kilometers) long and, as indicated in Table 2-11, relocating utilities in association with that bridge is estimated to cost $53.9 million. Based on the ratio of bridge lengths, the cost of line relocation with a bridge from Roanoke Island to Rodanthe would be approximately 26 percent higher ($67.8 million). A further additional cost would be the cost of the substation relocation and any costs that could be associated with the diversion of power from lines on Hatteras Island to lines on Roanoke Island.

The accumulation of severe problems described above outweighs the importance of protecting the 30,319 acre (12,270 hectare) Seashore from the use of the 6.3 to 7.3 acres (2.6 to 3.0 hectares) that would be required to complete the project with one of the other alternatives under consideration. Therefore, the Bridge from Rodanthe to Roanoke Island Avoidance Alternative is determined not to be a feasible and prudent avoidance alternative because the alternative would result in severe disruption to the established community of Wanchese, not meet the project's purpose and need, severely impact the operations of emergency services from Hatteras Island, and require substantial utility relocation.

5.3.3 Build the Replacement Bridge Completely within the Existing NC 12 Right-of-Way Avoidance Alternative

The Parallel Bridge Corridor with Phased Approach/Rodanthe Bridge Alternative (Preferred) avoids a Section 4(f) impact to the Seashore and the Refuge on Hatteras Island by building the project within the existing NC 12 easement, including the southern terminus of the Oregon Inlet bridge. Construction of the southern terminus of the Oregon Inlet bridge in the existing easement requires the demolition of the Bonner Bridge's southern terminus to provide room to accommodate the new bridge's southern terminus. Traffic operations would be maintained by building an approximately 2,600-foot-long (793-meter-long) traffic maintenance bridge to carry NC 12 traffic until the new southern terminus is completed. This is a reasonable and feasible approach because of the relatively short distance of temporary bridge involved. For the balance of the project within the Refuge and Seashore on Hatteras Island, a temporary road could be built to maintain NC 12 traffic operations in the existing easement during construction. Road construction is far less expensive than bridge construction.

The approach of staying within the existing easement/right-of-way applied on Hatteras Island, however, would not be a reasonable and prudent approach to avoiding a Section 4(f) use in the rest of the Seashore. Off of Hatteras Island, the Seashore encompasses most of Oregon Inlet and the area behind Bodie Island (see Figure 5-3). Almost all of NC 12 in this area is on Bonner Bridge. Bonner Bridge is centered on an existing 100-foot (30.5-meter) wide right-of-way. Bonner Bridge is 33.3 feet (10.1 meters) wide, leaving 33.4 feet (10.2 meters) of right-of-way on either side of the bridge. It would not be physically possible to build the new Oregon Inlet bridge

(42.6 feet [13.0 meters]) wide in that space while maintaining traffic. It would not be prudent to build a narrow (26-foot [7.9-meter] wide) temporary bridge for an additional distance of approximately 10,300 feet (3,139 meters) beyond the 2,600-foot-long (793-meter-long) traffic maintenance bridge discussed in the previous paragraph (i.e., the rest of the way across Oregon Inlet), demolish the existing bridge, build the new bridge over Oregon Inlet, and then demolish the temporary bridge. The end result would be NCDOT essentially building and demolishing two bridges with associated costs and environmental impact. Thus, this does not represent a feasible and prudent alternative.

There is no feasible and prudent avoidance alternative to the use of Section 4(f) property to construct the proposed action.

5.4 Least Harm Analysis

The sheer size and location of the Seashore and Refuge within the project area make it impossible to design an alternative that would avoid using any Section 4(f) property (see Figure 5-1). Section 5.3 of this Section 4(f) Evaluation documented that no feasible and prudent avoidance alternatives exist (i.e., all alternatives use Section 4(f) properties). In circumstances like this, where FHWA determines that there is no feasible and prudent avoidance alternative, the Section 4(f) regulations require FHWA to identify, from among the alternatives using Section 4(f) property, the alternative that causes the least overall harm. The regulations determine which alternative would cause the least overall harm with a balancing test that compares seven different aspects of the alternatives. Therefore, an assessment of the alternatives carried forward for detailed study (i.e., the five Parallel Bridge Corridor alternatives [including the Preferred Alternative] and the two Pamlico Sound Bridge Corridor alternatives) was conducted to determine which alternative meets the requirements of 23 CFR 774.3(c) for causing the least overall harm.

The Section 4(f) regulations, 23 CFR 774.3(c), specify that the alternative that causes the least overall harm is determined by balancing seven specific factors. These factors are:

1. The ability of the alternatives to mitigate adverse impacts to each Section 4(f) property (including any measures that result in benefits to the property);

2. The relative severity of the remaining harm, after mitigation, to the protected activities, attributes, or features that qualify each Section 4(f) property for protection;

3. The relative significance of each Section 4(f) property;

4. The views of the official(s) with jurisdiction over each Section 4(f) property;

5. The degree to which each alternative meets the purpose and need for the project;

6. After reasonable mitigation, the magnitude of any adverse impacts to resources not protected by Section 4(f); and

7. Substantial differences in costs among the alternatives.

A discussion is contained in the sections below to address these factors and provide the basis for the determination of the alternative that causes least overall harm. For this analysis, the two main

corridors, the Parallel Bridge Corridor (including the Preferred Alternative) and the Pamlico Sound Bridge Corridor, are compared. For many of the factors, the alternatives within the corridors are the same. Where there is a difference between the alternatives within the corridors under a factor, the differences are explained. The alternatives within the two main corridors are:

- Pamlico Sound Bridge Corridor:
  - With Curved Rodanthe Terminus; and
  - With Intersection Rodanthe Terminus.
- Parallel Bridge Corridor:
  - With Nourishment;
  - With Road North/Bridge South;
  - With All Bridge;
  - With Phased Approach/Rodanthe Bridge (Preferred); and
  - With Phased Approach/Rodanthe Nourishment.

5.4.1 Ability to Mitigate Adverse Impacts and Relative Severity of Remaining Harm

Below are combined discussions of the first two factors, the mitigation considered for impacts to the Section 4(f) properties used and the relative severity of the remaining harm to Section 4(f) properties for each alternative after mitigation. Section 4.7.10 contains a more complete discussion of all mitigation activities for the alternatives.

5.4.1.1 Cape Hatteras National Seashore on Bodie Island

All of the alternatives would avoid impacts to the activities, features, and attributes that qualify the Seashore on Bodie Island as a Section 4(f) property. More specifically, the alternatives were designed to avoid impacting the Seashore on Bodie Island (see Sections 2.4 and 2.6), and this resource would not be substantially affected by any of the alternatives (including the Preferred Alternative).

Impacts

The only impacts of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) and the Pamlico Sound Bridge Corridor alternatives within the Seashore on Bodie Island that are great enough to warrant mitigation would be those related to small potential construction-related impacts to piping plover nesting, and construction access impacts (dredging, work bridge, and/or haul road) to natural resources behind Bodie Island. Mitigation of wetland impacts that could result from construction or demolition access activities on Bodie Island (0.52 acres [0.21 hectares]) would consist of restoring these areas to their pre-construction condition following completion of this project. These areas would be replanted immediately following the restoration of the pre-construction elevation in order to provide rapid coverage and to prevent erosion. Species composition of the plantings would be based on pre-construction baseline data on species

composition of the areas to be impacted. Detailed monitoring of hydrology and vegetation would be conducted in order to ensure a return to full wetland function. A more complete description of mitigation for waters of the US can be found in Section 4.7.10.

The Parallel Bridge Corridor alternatives (including the Preferred Alternative) would require the permanent use of 6.3 acres (2.6 hectares) of the Seashore on Bodie Island. The Pamlico Sound Bridge Corridor alternatives would require 7.3 acres (3.0 hectares). Bonner Bridge currently occupies a corridor consisting of approximately 6.3 acres (2.6 hectares) that bisects the Seashore on Bodie Island. This corridor would be restored and returned to the Seashore after Bonner Bridge is demolished and removed. Other than the current Bonner Bridge corridor, there is no non-Seashore property in the area of the use that could be acquired and added to the Seashore as additional mitigation. Therefore, there would be no net loss of Section 4(f) property with the Parallel Bridge Corridor alternatives (including the Preferred Alternative), but an unmitigatable 1.0 acre (0.4 hectare) net loss of Seashore property with the Pamlico Sound Bridge Corridor alternatives. All of the alternatives were designed to avoid impacts to Seashore activities, features, and attributes that qualify the Seashore on Bodie Island as a Section 4(f) property. All alternatives would equally restrict the access of fishing vessels from the Oregon Inlet Marina and Fishing Center from following the "crack," a short cut to the ocean from the Marina. This would result in an average increase of approximately 30 minutes of travel time to reach Oregon Inlet. As stated in Section 5.2.1.1, this increased travel time is not a use of Section 4(f) property, but it does represent an impact on people who travel by boat between the Marina and Oregon Inlet.

In summary, after mitigation, all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would cause slightly less harm to the Seashore on Bodie Island than the Pamlico Sound Bridge Corridor alternatives. After mitigation (return of the land currently occupied by Bonner Bridge) the Seashore would not lose any net area with the Parallel Bridge Corridor alternatives, but would lose approximately 1.0 acre (0.4 hectare) with the Pamlico Sound Bridge Corridor alternatives. This 1.0 acre (0.4 hectare) net difference is considered important but not critical because the Seashore contains 30,319 acres (12,270 hectares) of land, so the 1.0 acre (0.4 hectare) net use is a very minor impact.

Conclusion

Therefore, the FHWA and NCDOT consider the two replacement bridge corridors (including the seven alternatives within the two replacement bridge corridors) to be substantially equal in terms of the agencies' ability to mitigate the adverse impacts to the Seashore on Bodie Island.

5.4.1.2 Pea Island National Wildlife Refuge/Cape Hatteras National Seashore on Hatteras Island

The following is a summary of the mitigation that has been considered for impacts on Section 4(f) resources on the Refuge and the remaining harm for each alternative. It should be noted that of the Parallel Bridge Corridor alternatives, only the Phased Approach/Rodanthe Bridge Alternative (Preferred) stays completely within the existing easement within the Refuge and, therefore, does not constitute a use of the Refuge under Section 4(f). The Pamlico Sound Bridge Corridor alternatives also avoid the use of Refuge lands.

Use of Refuge Land

As can be seen in Table S-1, all of the Parallel Bridge Corridor alternatives would have a use of the Refuge with the exception of the Phased Approach/Rodanthe Bridge Alternative (Preferred). The Nourishment Alternative would use 19.9 acres (8.1 hectares) of the Refuge, mostly through affecting the dunes and beach areas with beach nourishment and dune maintenance activities.

The Road North/Bridge South Alternative would use 93.4 acres (37.8 hectares) of the Refuge. The horizontal shift of NC 12 to the west would change the appearance of the surrounding terrain, change wetland to road, and narrow the ponds as much as 700 feet (213.4 meters). This alternative also would cross the dikes around the ponds, as well as the wildlife trails on top of the dikes associated with the northernmost pond. The All Bridge Alternative would use 92.2 acres (37.3 hectares) of the Refuge. The bridge through the Refuge with this alternative would be built as much as 900 feet (274.4 meters) west of existing NC 12. The bridge structure would pass above the wildlife trails on top of the dikes associated with the northernmost pond and over the ponds. The bridge would dominate views from the wildlife trails. The Phased Approach/ Rodanthe Nourishment Alternative would use approximately 1,500 feet (457.2 meters) of shoreline for nourishment activities just north of Rodanthe. The Phased Approach/Rodanthe Bridge Alternative (Preferred) and Pamlico Sound Bridge Corridor alternatives would not use any property from the Refuge/Seashore.

Since the Pamlico Sound Bridge Corridor alternatives and the Phased Approach/Rodanthe Bridge Alternative (Preferred) are the only alternatives that avoid permanently incorporating land from the Refuge, the FHWA and NCDOT consider them to be substantially equal as the best options in terms of use of Refuge lands under the requirements of Section 4(f).

Loss of Recreation Access

Though recreation is not defined as the primary purpose of the Refuge, it is a popular area for fishing, surfing, and other activities. With the Pamlico Sound Bridge Corridor, NC 12 between Bodie Island and Hatteras Island no longer would pass through the Refuge. Paved road access would continue in the Refuge with the Parallel Bridge Corridor. Access would focus on three points in the Refuge with the All Bridge Alternative and two points with the Phased Approach alternatives (including the Preferred Alternative). Access would be lost to the Refuge Visitor Center, headquarters, and North Pond Trail with the All Bridge and Phased Approach alternatives (including the Preferred Alternative).

When the first phase of the two Phased Approach alternatives (the new Oregon Inlet bridge) is complete, the bridge built to provide a temporary connection between Bonner Bridge and Hatteras Island while the replacement bridge is built in the existing easement could be left in place to be used as a fishing pier, replacing the existing catwalks. This could also occur with the Nourishment Alternative, which also would involve replacing the bridge in the existing easement at the north end of Hatteras Island. At this time, one viable approach for maintaining fishing access with the Pamlico Sound Bridge Corridor, the Parallel Bridge Corridor with Road North/Bridge South, and the Parallel Bridge Corridor with All Bridge alternatives appears to be leaving a portion of the Bonner Bridge for fishing. However, in order to maintain a portion of Bonner Bridge as a fishing pier, some government body or non-governmental organization would have to take responsibility for pier operation, maintenance, and liability. Construction of a "boardwalk" on top of the riprap that currently blankets the northern shore of Hatteras Island is another option.

Unlike the other Parallel Bridge Corridor alternatives, the Phased Approach alternatives (including the Preferred Alternative) would directly affect activities on the beach front, including fishing, hiking, surfing, wind surfing, kite boarding, swimming, ocean kayaking, and birding. Bridge piles in the ocean could change the types of fish that congregate around the shore. To the extent that certain sections of the bridged roadway would be over the beach, beach activities would be affected, but not precluded, by the presence of the bridge and bridge piles. Once the Phased Approach alternatives' bridge piles are in the ocean, the ability to surf in a particular area would be eliminated. The piles would change how and where the waves break, which would

interfere with the swells in such a way that the waves would no longer be conducive to good surfing. In addition, the presence of bridge piles every 120 feet (36.6 meters), in areas where the bridges would be less than 150 feet (45.7 meters) from shore, would be a safety hazard to surfers and other recreational ocean users. A complete description of the changes in recreational access to the Refuge is included in Section 4.5.3.

With the Pamlico Sound Bridge Corridor alternatives, however, access to fishing at either Oregon Inlet or within the Refuge would be more difficult because there would be no paved road within the Refuge as there would be with the Parallel Bridge Corridor alternatives (including the Preferred Alternative), as discussed in Section 5.2.2.2.

The Parallel Bridge Corridor alternatives (including the Preferred Alternative) are considered the best option by FHWA and NCDOT for maintaining recreational opportunities at Oregon Inlet and within the Refuge. With the Pamlico Sound Bridge Corridor alternatives, access to these areas would be limited because of the likely loss of paved road access.

Protected Species

As discussed in Section 4.7.9, the Pamlico Sound Bridge Corridor would not likely result in adverse impacts to the 13 federally-listed threatened or endangered species in Dare County. With the Pamlico Sound Bridge Corridor, the biological conclusion for 10 of these species is "May Affect – Not Likely to Adversely Affect," and the biological conclusion for three species is "No Effect."

The remaining discussion refers to mitigation and remaining harm for the Parallel Bridge Corridor alternatives (including the Preferred Alternative).

With the Parallel Bridge Corridor alternatives (including the Preferred Alternative), the biological conclusion for six of these species (five species with the Nourishment and Phased Approach/ Rodanthe Nourishment alternatives) is "May Affect – Not Likely to Adversely Affect," the biological conclusion for three species is "No Effect," and the biological conclusion for four species (five species with the Nourishment and Phased Approach/Rodanthe Nourishment alternatives) is "May Affect – Likely to Adversely Affect." These species include the piping plover, leatherback sea turtle, green sea turtle, loggerhead sea turtle, and the seabeach amaranth. Formal consultation was completed with the USFWS for the Phased Approach/Rodanthe Bridge Alternative (Preferred), and concurrence was obtained on biological conclusions from both the USFWS and National Marine Fisheries Service (NMFS). The biological opinions resulting from the formal consultation with the USFWS is reflected in the biological conclusions and discussed in Section 4.7.9.

Conservation measures agreed to with the USFWS and the NMFS for species under their jurisdiction are described in Section 4.7.10.4 for the Phased Approach/Rodanthe Bridge Alternative (Preferred). They also are incorporated in the Project Commitments. Reasonable and prudent measures and associated terms and conditions to minimize take of the piping plover, loggerhead sea turtle, green sea turtle, and leatherback sea turtle were also agreed to with the USFWS and are also presented in Section 4.7.10.4 and included in the Project Commitments. Though consultation was only completed for the Phased Approach/Rodanthe Bridge Alternative (Preferred), many of the terms and conditions could be applied to the other Parallel Bridge Corridor alternatives. However, additional mitigation measures likely would be required for the two Parallel Bridge Corridor alternatives that utilize beach nourishment.

FHWA and NCDOT believe that the remaining harm, after mitigation, to these species would be minor. The USFWS concurred that the proposed action would not jeopardize the continued existence of any endangered or protected species, and would not result in the destruction or adverse modification of habitat of such species. The USFWS agreed that there may be a take of the piping plover, loggerhead turtle, leatherback turtle, and the green sea turtle, as well as the proposed critical habitat of the piping plover. An incidental take statement for these species and the piping plover critical habitat has been issued by the USFWS. The FHWA and NCDOT consider the two replacement bridge corridors (including the alternatives within the two replacement bridge corridors) to be substantially equal in terms of the remaining harm to protected species in the Refuge after mitigation.

Historic

A more thorough discussion of impacts to the Refuge as a historic resource can be found in Section 4.4.1. The Phased Approach/Rodanthe Bridge Alternative (Preferred) does not permanently incorporate land from the Refuge. It does not constitute a use of Refuge property under Section 4(f), though it does have an Adverse Effect on the Refuge as a historic resource.

The Parallel Bridge Corridor with Nourishment Alternative would avoid impacts to the Refuge as a historic resource by maintaining the existing shoreline and the status quo regarding the historic CCC facilities. The Nourishment Alternative, as stated above, also would most protect Refuge facilities, including the landscape that contributes to its NRHP-eligibility. Also, as discussed in Section 5.2.2.1, current access to the Refuge facilities would be maintained. The Road North/Bridge South and All Bridge alternatives would have the most impacts to the historic CCC facilities, because both of the alternatives would place NC 12 over the existing dikes and ponds.

As discussed in Section 5.2.2.1, a replacement bridge within the Parallel Bridge Corridor would provide a paved road the full length of the Refuge. The Parallel Bridge Corridor with Road North/Bridge South and All Bridge alternatives, however, would bypass the Refuge Visitor Center, the North Pond Trail, the Refuge headquarters, and the boat ramp (see Figure 5-4a and Figure 5-4b). The Phased Approach alternatives (including the Preferred Alternative) would reduce Refuge access the most of the various Parallel Bridge Corridor alternatives. Once the full project is complete, only two access points off of NC 12 would be provided in the Refuge. The first access point would be the interchange adjacent to the fishing catwalks parking lot that would be started during Phase I and completed during Phase II. In Phase I, the Oregon Inlet bridge would be built and would end as a stub on Hatteras Island in the existing easement and adjacent to the catwalks parking lot. Ramps would be built on either side of the bridge to bring traffic down to the existing road. During Phase II, the bridge would be extended south and a second set of ramps would be built. The ramps would function as a highway interchange to bring NC 12 traffic down to the existing parking lot (see Section 2.10.1.2 and Figure 2-22). The second access point would be south of the ponds in the 2.1-mile (3.4-kilometer) section of NC 12 in the southern half of the Refuge that is not expected to be threatened by erosion prior to 2060 (see Figure 5-4b).

Potential mitigation strategies for impacts from the Phased Approach/Rodanthe Bridge Alternative (Preferred) on the Refuge as an historic resource were discussed with the Section 106 consulting parties at a July 10, 2008 meeting in Manteo, North Carolina. Although specific mitigation commitments will be fully documented in the final Section 106 MOA, some examples of potential mitigation include:

- Design bridge rail so that drivers can view Refuge;
- Research context for CCC involvement along the North Carolina coastline;
- Identify and map shipwrecks;
- Provide signs to direct people to the Refuge Visitor Center and view CCC installations;
- Provide USFWS information for the NRHP nomination, including previous historic architecture, terrestrial archaeology, and underwater archaeology surveys;
- Install interpretative text/displays and kiosks to provide visitors with information about historic significance of site; and
- Maintain access to site, including restoring road as part of staging for construction, possibly installing power, and creating visitor parking.

As discussed in Section 5.2.2.2 for the Pamlico Sound Bridge Corridor alternatives, although the USFWS and the NPS have indicated that they intend to maintain some type of access within the Refuge, the method of access would not likely be a paved road between Rodanthe and Oregon Inlet. There would be a reduction in visitors to the Refuge because of the loss of paved road access with associated economic impacts to Dare County (see Section 4.1.5.3). Regarding visual impacts, the Pamlico Sound Bridge Corridor alternatives would minimize impacts to views from the Refuge that are an attribute of its historic character. The Pamlico Sound Bridge Corridor alternatives would still be visible in parts of the Refuge, but not as visible as the Parallel Bridge Corridor alternatives (including the Preferred Alternative). No specific mitigation has been identified for the Pamlico Sound Bridge Corridor alternatives.

With regard to all alternatives, the FHWA and the NCDOT consider the Parallel Bridge Corridor with Nourishment Alternative to have the least impact to the Refuge as a historic resource by maintaining the existing shoreline and the status quo regarding the historic CCC features. The most substantial of the remaining harm to the Refuge as a historic resource is the visual impact of an elevated structure as proposed for the Phased Approach alternatives (including the Preferred Alternative) and the All Bridge Alternative. However, the Refuge would remain eligible for the NRHP and the historic features and attributes of the Refuge would not be substantially impaired, as discussed in Section 5.5. Overall, the Pamlico Sound Bridge Corridor alternatives, the All Bridge Alternative, the Road North/Bridge South Alternative, and the Phased Approach alternatives (including the Preferred Alternative) are considered to result in substantially equal harm after mitigation from a historic resource perspective. Although the Pamlico Sound Bridge Corridor alternatives were determined to have No Effect on the Refuge as defined in the regulations of the Advisory Council of Historic Preservation, the loss of visitors because of loss of paved road access was considered in determining the degree of harm to the Refuge as a historic resource.

Natural Systems – Wetlands and Biotic Communities

The biotic community impacts from fill by the Parallel Bridge Corridor alternatives would vary by alternative. The greatest impacts to biotic communities within the Refuge would come with the Road North/Bridge South Alternative at 60.98 acres (24.69 hectares). The Refuge biotic community impacts for the other Parallel Bridge Corridor alternatives (from greatest to least) would be: 19.92 acres (8.06 hectares) for the Nourishment Alternative; 7.95 acres (3.22 hectares) for the All Bridge Alternative; and 3.67 acres (1.49 hectares) for the two Phased Approach alternatives (including the Preferred Alternative). The land devoted to the existing road would be

returned to the Refuge for the All Bridge and Road North/Bridge South alternatives. Construction within the ponds in the interior of the Refuge associated with the Road North/Bridge South and All Bridge alternatives would generate localized impacts to water quality. These impacts would be temporary and most likely affect turbidity and siltation of sediments. The Pamlico Sound Bridge Corridor alternatives would have no impacts on biotic communities and wetlands within the Refuge.

Regarding wetland mitigation (as described in Section 4.7.10.3), the 1990 MOA related to wetland mitigation between the USACE and the USEPA states that "appropriate and practicable compensatory mitigation is required for unavoidable adverse impacts which remain after all appropriate and practicable minimization has been required." Compensatory mitigation refers to the restoration, creation, enhancement, or preservation of wetlands as compensation for unavoidable wetland impacts. Temporary impacts to wetlands would be mitigated on a 1:1 basis by restoring these areas to their pre-construction condition. Species composition of the plantings would be based on pre-construction baseline data on species composition of the affected areas. Detailed monitoring of hydrology and vegetation would be conducted in order to ensure a return to full wetland function. Permanent wetland losses would be mitigated by restoring, creating, or enhancing wetlands at agency-approved ratios. Potential compensatory wetland mitigation includes on-site restoration and enhancement of in-kind wetlands as compensation for as much of the permanently affected area as possible; however, the limited availability of potential mitigation sites in the immediate vicinity of the project area would necessitate an exploration of additional options, which include off-site restoration, creation, and enhancement of wetlands. Mitigation credit available from the Ballance Farm Mitigation Site in Currituck County could provide for all or a portion of the mitigation required for the Phased Approach/Rodanthe Bridge Alternative (Preferred). The amount of mitigation credit available from this site cannot be currently determined because other projects could debit credit from the site. Any mitigation not accounted for by the Ballance Farm would be reconciled through onsite mitigation and monetary contributions to North Carolina's *Ecosystem Enhancement Program* (EEP).

Some wildlife habitat would be regained by removing the existing NC 12 pavement where it is no longer needed and replanting with native vegetation. This habitat would not be equivalent to native, undisturbed habitat. However, potential habitat created by the removal of replaced portions of NC 12 could be colonized very quickly by ephemeral species that inhabit maritime islands. Natural shoreline movement, allowed to occur with most of the alternatives (including the Preferred Alternative), also would contribute to naturalizing this area of the Outer Banks, and benefiting wildlife in the Refuge.

The FHWA and NCDOT consider the Road North/Bridge South Alternative to have the greatest harm to wetlands and biotic communities. Since the other alternatives (including the Preferred Alternative) impact wetlands and biotic communities to a substantially lesser degree than the Road North/Bridge South Alternative, the FHWA and NCDOT consider the other alternatives within the two replacement bridge corridors to be substantially equal in this respect after mitigation as described above.

Natural Systems - Natural Shoreline Movement

As discussed in Section 4.7.7, a return to allowing natural changes in the barrier island environment to take place, including new inlet formation and shoreline migration, is a priority for the NPS and the Refuge. Taking into account natural changes in the barrier island environment is also a component of the project's purpose and need (see Section 1.2). The Nourishment Alternative would not allow for the natural barrier island processes. The other Parallel Bridge Corridor alternatives (including the Preferred Alternative), as well as the Pamlico Sound Bridge

Corridor alternatives, would allow for natural barrier island change to occur, with the exception of the 0.4 mile (0.6 kilometer) of dunes defined as a part of the Road North/Bridge South Alternative and the nourishment associated with the Phased Approach/Rodanthe Nourishment Alternative. In addition, all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would require the retention of the terminal groin.

FHWA and NCDOT consider the Pamlico Sound Bridge Corridor alternatives, as well as the Parallel Bridge Corridor with All Bridge Alternative and the Phased Approach/Rodanthe Bridge Alternative (Preferred), to be the best in terms of allowing natural process to take place, and also consider them to be substantially equal in terms of remaining harm. The Phased Approach/ Rodanthe Nourishment and the Road North/Bridge South alternatives have slightly more unmitigatable impacts, with the Nourishment Alternative having the most unmitigatable impacts on natural shoreline movement.

Conclusion

The FHWA and NCDOT consider the Pamlico Sound Bridge Corridor alternatives to have the least harm to the Refuge/Seashore on Hatteras Island because these alternatives would not be within the Refuge. The Phased Approach/Rodanthe Bridge Alternative (Preferred) would be confined to the existing easement, reducing its potential impact by not using Refuge lands, providing for fishing access, minimizing protected species impacts, minimizing direct impacts to habitat, and allowing for shoreline erosion. The other Parallel Bridge Corridor alternatives would cause greater harm after mitigation to the Refuge/Seashore on Hatteras Island because they would use from 1,500 feet (457.2 meters) of shoreline to 93.4 acres (37.8 hectares) of the property.

5.4.1.3 (Former) Oregon Inlet US Coast Guard Station

A replacement bridge in the Parallel Bridge Corridor would retain NC 12 through the Refuge and terminate at the southern tip of Bodie Island. All of the Parallel Bridge Corridor alternatives (including the Preferred Alternative) would introduce a taller or longer bridge into the viewshed of the (former) Oregon Inlet US Coast Guard Station resulting in an Adverse Effect from a historic resource perspective. However, no property would be used with any of the Parallel Bridge Corridor alternatives.

The Parallel Bridge Corridor could allow for the relocation of the (former) Oregon Inlet US Coast Guard Station across Oregon Inlet (most likely by barge) as discussed in Section 4.4.1.2 under "(Former) Oregon Inlet US Coast Guard Station." The retention of the terminal groin, required by all of the Parallel Bridge Corridor alternatives, would allow the station to remain on its current site, if desired by its owners. If it remains at its current site, road access to the station would remain with all of the Parallel Bridge Corridor alternatives (including the Preferred Alternative).

The Pamlico Sound Bridge Corridor alternatives would not require any use of the (former) Oregon Inlet US Coast Guard Station. Although the Pamlico Sound Bridge Corridor alternatives would minimize visual impacts to the property as compared to the Parallel Bridge Corridor alternatives, these alternatives would have an Adverse Effect on the property because of the potential for loss of access to the facility and the potential for the removal of the terminal groin at the northern end of Hatteras Island upon completion of the proposed project. If the groin is removed, the northern end of Hatteras Island would continue its southward migration (see Section 3.6.2.5) and, unless relocated, the (former) Oregon Inlet US Coast Guard Station would be washed away. Because of the current condition of Bonner Bridge, further consideration would have to be given to determine if the Bonner Bridge can safely bear the weight of the station in the attempt to relocate the structure to

the north. However, a barge could be used to relocate the structure to a new site to the north on Bodie Island should that be the desire of the North Carolina Aquarium Society.

Potential mitigation strategies for impacts from the Phased Approach/Rodanthe Bridge Alternative (Preferred) on the (former) Oregon Inlet US Coast Guard Station were discussed with the Section 106 consulting parties at a July 10, 2008 meeting in Manteo, North Carolina. Although specific mitigation commitments will be fully documented in the final Section 106 MOA, some examples of potential mitigation, not only limited to the Phased Approach/Rodanthe Bridge Alternative (Preferred), include:

- Restoration and interpretive displays/kiosks providing visitors with information about the historic significance of the site;
- If the terminal groin is removed, help in moving building to a new site;
- Provide signs to direct people to the site;
- Provide information for cultural interpretive exhibits;
- Update the NRHP nomination and develop measured drawings/structural report for the station; and
- Joint marketing for tourism with other US Coast Guard and Life Saving stations along the Outer Banks.

Conclusion
